Ranavirus Infection in Die-offs of Vernal Pool Amphibians in New York, USA

Amphibian ranaviruses have an apparently wide distribution in North America. The type virus in the genus *Ranavirus*, frog virus 3 (FV3), was isolated from aclinically infected leopard frogs (*Lithobates pipiens*) collected in Wisconsin and Minnesota in 1962 (Granoff et al. 1965). Since then, FV3-like viruses have been identified in California (Mao et al. 1999), Saskatchewan (Schock et al. 2008), Tennessee (Gray et al. 2007), North Carolina (Petranka et al. 2003), Alabama and Arkansas (Wolf et al. 1969), Ontario (Greer et al. 2005), Vermont (Clark et al. 1968), and Maine (Bank et al. 2007). To date, however, ranaviruses have not been reported from amphibians in New York State, although they have been isolated from Eastern Box Turtles (*Terrapene carolina carolina*) on Long Island, New York (Johnson et al. 2008). Here we report that FV3-like ranaviruses are widespread in New York State and associated with recurrent die-offs of larval Spotted and Jefferson Salamanders (*Ambystoma maculatum* and *A. jeffersonianum*) and Wood Frog tadpoles (*Lithobates sylvaticus*) in vernal pools.

During routine monitoring of vernal pools for amphibian breeding from May through early July in 2008 and 2009, we noted die-offs in several vernal pools in four locations in New York: the Albany Pine Bush, the Huntington Wildlife Forest in the Adirondack Mountains, the Teatown Lake Reservation in the lower Hudson Valley, and the Mohonk Preserve in the Shawangunk Mountains.

In each case, live larvae or tadpoles were haphazardly collected by hand or with a dip net, sent to the laboratory of JLB in pond water on ice, and frozen at -80°C until they could be screened for ranavirus infection. Samples were collected opportunistically and so sample sizes varied and were generally small. Samples from the Albany Pine Bush and Teatown Lake Reservation were bagged by pond rather than individually such that their independence cannot be guaranteed. Care was taken, however, to prevent contamination between ponds by disinfecting sampling equipment between ponds with a 10% bleach solution.

In early to mid-May 2008, KEB and CG visited a pond and vernal pool (ca. 150 m apart) located in the Albany Pine Bush where essentially every tadpole (apparently all *L. sylvaticus*) visible from shore or caught with a dip net was moribund or dead. The tadpoles had edema, diffuse petechial lesions along the ventral surface, especially near the cloaca and base of the tailfin, and about a third had a torn peritoneum, apparently because their abdomens were severely bloated. Similar mortality events were not observed in these two ponds during the two or three visits per breeding season in the previous several years. In 2009, both ponds dried by mid June, earlier than usual, and no apparent disease-associated mortality was noted.

In mid-June 2008, SAM observed dying *L. sylvaticus* tadpoles in three of eight vernal pools that have been regularly monitored for amphibian breeding in the Huntington Wildlife Forest (HWF), Essex County, New York, in the Adirondack Mountains. Moribund (listless, occasionally edematous, with petechial lesions) and apparently healthy *A. maculatum* larvae as well as *L. sylvaticus* tadpoles were collected from four vernal pools, one of which had obvious signs of mortality (pond VP65-2; named according to a grid at the HWF) and three of which did not (VP43-2, VP73-3, and VP70-1). In VP65-2, an apparently healthy adult, female Green Frog (*L. clamitans*) was captured by hand and a toe-clip was taken with a sterile razor blade. On 10 June 2009, moribund and dead *L. sylvaticus* tadpoles were found in two ponds that were sampled the previous year (VP43-2 and VP65-2) and one that had not (VP42-1). Five live tadpoles were collected across all three ponds.

On 19 June 2008, MJR noticed dead wood frog tadpoles in a vernal pool (HV2) at the Teatown Lake Reservation, in Westchester County, New York in the lower Hudson Valley; many more dead tadpoles were observed 26 June. On 30 June 2008 one to two live individuals per species were collected from each of five ponds: three (HV2, HV3, and HV4) where dead and dying *Ambystoma* larvae, probably *A. maculatum*, were noted, along with apparently healthy Grey Tree Frog tadpoles (*Hyla versicolor*), and two (CL1, and DH2) where dead *L. sylvaticus* tadpoles were found. One other vernal pool observed on that day did not have signs of mortality and no samples were collected from it. Five of seven vernal pools at Teatown Lake Reservation had die-offs of amphibian larvae in early July 2009 as well, but samples were not collected.

On 15 June 2009, MBK found a die-off in the James Stokes vernal pool in the Mohonk Preserve, Ulster County. Many dead *L. sylvaticus* tadpoles were found as well as apparently healthy and moribund *A. maculatum* and *A. jeffersonianum* larvae. Two

TABLE 1. *Ranavirus* infection status, no. positive samples/no. tested, of amphibian samples from New York, USA examined using both PCR of the MCP gene and virus isolation with cell culture. Parentheses represent animals that were transported in the same container; cross contamination cannot be ruled out. # indicates MCP gene was sequenced. * indicates lateral halves of the same individuals were tested by PCR.

of each ambystomatid species were collected alive, all with lesions and two with slight edema by the following day. Apparently healthy *H. versicolor* tadpoles and later metamorphs, and *L. clamitans* tadpoles were observed in this pond during periodic sampling at James Stokes vernal pool throughout the rest of the summer. No morbidity or mortality was noted during a visit two weeks earlier, or at another study site, North Mud pond. These two ponds had been studied extensively in the previous two years, but this was the first time a die-off was observed.

The carcasses or, for larger animals, one lateral half of a carcass was ground in cell lysis buffer with ca. 1 ml silicone-carbide sharp particles (1 mm diameter) using a Bead Beater 96 (Biospec Products, Bartlesville, Oklahoma, USA) and digested with 10 µl Proteinase K. DNA was then extracted using a standard salt extraction protocol (Sambrook and Russell 2001). In order to minimize surface contamination, the samples from Teatown and the Albany Pine Bush, which were bagged and transported in groups, were surface sterilized with a 10% solution of commercial bleach in water and then rinsed with distilled water before being placed in an individual tube and extracted. It is impossible, however, to guarantee independence among these samples. Animals from the Adirondacks and Mohonk Preserve were individually bagged.

Samples were screened with PCR using primers MCP4 and MCP5 (Mao et al. 1997), which target a ca. 500 bp region of the 5' end of the major capsid protein (MCP) gene. PCR products were separated by gel electrophoresis on 1.5% agarose gels and visualized with ethidium bromide staining. Samples were tested at least twice, but up to four times to resolve ambiguous or contradictory results, and scored by majority rules.

PCR products from two *L. sylvaticus* from the Albany Pine Bush, two *A. maculatum* from the Huntington Wildlife Forest, and three *Ambystoma* sp. from the Teatown Lake Reservation (Table 1) were purified using the QIAEX II gel extraction kit (Qiagen, Valencia, California, USA) and submitted to the Nevada Genomics Laboratory for sequencing in the forward direction. Sequences were aligned using Geneious 4.0.2 (Biomatters Ltd.) resulting in a common 471 bp of sequence.

Virus isolation was attempted in the laboratory of JLB on six dead *L. sylvaticus* tadpoles from the Albany Pine Bush; five moribund *L. sylvaticus* tadpoles from the Huntington Wildlife Forest; one moribund and one dead *A. maculatum* and two moribund *A. jeffersonianum* larvae from the Mohonk Preserve; and the un-extracted lateral halves of two *L. sylvaticus* tadpoles and three *Ambystoma* larvae from the Teatown Lake Reservation (Table 1). Samples were homogenized in 5% fetal bovine serum in minimum essential medium with Hanks salts (HyClone, Ottawa, ON, Canada) in tubes filled with silicone-carbide sharp particles (Biospec Products) using a Mini-Beadbeater-96 (Biospec Products). The homogenates were then filtered

through a 0.45-µm filter and inoculated onto *epithelioma papulosum cyprini* (EPC) cells. Samples were passed twice, except for the sample from VP43-2 in which bacterial contamination prevented a second pass, and observed for signs of cytopathic effects using an inverted light microscope at 100× magnification. Isolation of ranavirus was verified using PCR, as above.

Twenty-two of 57 animals tested positive for ranavirus with PCR and ranavirus was isolated from 19 of 20 animals, including the lateral halves of two tadpoles that were negative by PCR (Table 1). Animals from all three regions tested positive, including *Ambystoma* larvae and *L. sylvaticus* tadpoles, as well as the toe of one adult *L. clamitans*, which consistently produced weakly visible bands. Given our small samples sizes, imperfect diagnostic tests (Greer and Collins 2007), and because these samples were collected opportunistically from die-offs, which can occur very rapidly and last for only two or three weeks (Gray et al. 2009), it seems likely that our data underestimate the prevalence, geographic range, and host range of these ranaviruses. Indeed, ranaviruses have been identified in all of the species we tested (Duffus et al. 2008; Gray et al. 2009), even though we never detected ranavirus in *H. versicolor*.

The major capsid protein (MCP) gene sequences of all eight sequenced samples were identical to each other and to the published sequence of Frog Virus 3 (GenBank accession # AY548484) across all 471 bases. It is not clear whether these virus isolates are in fact a single, widespread virus. The MCP is highly conserved among ranavirus species, and so sequence data from the MCP gene alone is not sufficient to differentiate species (Chinchar et al. 2009). Moreover, Schock et al. (2008) have shown that ranavirus isolates with identical MCP sequences can have distinct restriction profiles and perhaps different ecology interactions. Isolates from *L. sylvaticus* and *A. maculatum* collected from two vernal pools in the Teatown Lake Reservation, however, were statistically indistinguishable in terms of the rate and timing of mortality that they caused in an LD_{50} study in *L. sylvaticus* (Warne et al. 2010) and *A. maculatum* (JLB, unpubl. data). Further study is required to determine whether there is one widespread or many, somewhat distinct ranaviruses in New York State.

We must emphasize that while ranaviruses are known to cause catastrophic mortality in larval amphibians (Gray et al. 2009) and several of the virus isolates we collected are highly lethal (Warne et al. 2010) we did not screen for other agents or complete a post mortem exam on these larvae and so we cannot conclude that ranavirus was the cause of these vernal pool die-offs, but merely that amphibians were infected with ranavirus during these die-offs. Whatever the cause, these were not the first die-offs noted in the Huntington Wildlife Forest, which has been systematically monitored for breeding activity every year since the mid 1990s. There was a report of "red-leg," which can be associated with ranaviral disease (Green et al. 2002), in *L. sylvaticus* tadpoles during mortality events in 1999 and 2000 (Quail 2001). Similarly, a die-off of *L. sylvaticus* tadpoles and *A. maculatum* larvae was observed in 2006, with moribund animals showing similar signs of infection as seen in the 2008 and 2009 die-offs. It is worth noting that there is no obvious sign of declines in breeding output in the vernal pools of the Huntington Wildlife Forest (SAM, unpubl. data). Moreover, die-offs may not be completely catastrophic to recruitment. Pond VP65-2, which had a die-off in mid-June of 2008, produced *L. sylvaticus* metamorphs by mid-July.

In summary, FV3-like ranaviruses were identified in live and dead *Ambystoma* larvae and *L. sylvaticus* tadpoles during mortality events in vernal pools across New York State. These epidemics and the occurrence of ranavirus recurred in the same ponds over two years, as has been observed elsewhere (e.g., Petranka et al. 2007). It remains to be determined whether these virus isolates represent a single widespread virus or whether there are several closely related strains of ranavirus with different ecologies. It is clear, however, that these virus isolates are capable of infecting multiple hosts. Whether they were the cause of the die-offs we observed or have long-term impacts on their host populations is not known, but the potential for ranaviruses to cause catastrophic mortality has been established (Gray et al. 2009; Green et al. 2002; Teacher et al. 2010). We urge amateur and professional biologists working in vernal pools in New York State to take basic steps to prevent the spread of these highly lethal viruses including washing and disinfecting boots and equipment between sites and taking care not to move water, sediment, or organic materials between ponds (Bryan et al. 2009; Green et al. 2009).

SSAR Silent Auction Donations

SSAR announces the Fifteenth Annual Silent Auction to be held at the 2011 Joint Meeting of Ichthyologists and Herpetologists (JMIH) in Minneapolis, 6–11 July. Again this year we are glad to accept any herp-related donations including but not limited to frameable art (photographs, paintings, and line illustrations), books, music, glassware, jewelry, clothing, and gift certificates for Minnesota area services/events during the meeting week. The SSAR Student Travel Committee organizes the Annual Silent Auction to raise money to fund the student travel awards to the JMIH. Increasing travel costs each year make it more difficult for students to attend meetings and become involved in societies. However, your continued support through donations to the silent auction helps offset these costs enabling students to attend, network, and present their research. If you are interested in donating an item or two (tax deductible for U.S. residents), please contact **Mike Jorgensen** (e-mail: mj207406@ohio.edu) for more information.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations in the field, with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Notes concerning captive animals should be directed to our Herpetoculture section (see inside front cover for section editor contact information).

Electronic submission of manuscripts is requested (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Color figures can be submitted electronically as JPG files, although higher resolution TIFF or PDF files will be requested for publication. Please DO NOT send graphic files as imbedded figures within a text file. Additional information concerning preparation and submission of graphics files is available on the SSAR web site at: http://www.ssarherps.org/HRinfo.html. Manuscripts should be sent to the appropriate section editor: **Jackson Shedd** (crocodilians, lizards, and *Sphenodon*; jackson.shedd@gmail.com); **Charles Painter** (amphibians; charles.painter@state.nm.us); **J. D. Willson** (snakes; hr.snake.nhn@gmail.com); and **James Harding** (turtles; hardingj@msu.edu).

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*. SSAR Herpetol. Circ. 37:1–84, available from SSAR Publications Secretary, ssar@herplit.com; for Mexico as it appears in Liner and Casas-Andreu 2008, *Standard Spanish, English and Scientific Names of the Amphibians and Reptiles of Mexico*. Herpetol. Circ. 38:1–162), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s), if relevant to your report. Then skip a line and close with name and address in full—spell out state or province names—no abbreviations. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Medina, P., and R. L. Joglar. 2008. *Eleutherodactylus richmondi*: reproduction. Herpetol. Rev. 39:460.

CAUDATA — SALAMANDERS

***AMBYSTOMA OPACUM* (Marbled Salamander). ALBINISM.** On 27 Sept 2009, I captured a gravid adult female (ca. 9.5 g) *Ambystoma opacum* in a wetland located at Bear Hollow Wildlife Management Area in Franklin Co., Tennessee, USA that was completely void of any pigmentation (Fig. 1) and is, therefore, a complete albino (e.g., complete lack of melanin, red eyes: Hensley 1959. Publ. Mus., Michigan State Univ. 1[4]:133–159). The albino, and 17 other gravid females displaying typical pigmentation, was captured in a pitfall trap as they migrated to a wetland (35.02035°N, 86.01425°W).

Various forms of albinism in *A. opacum* have been documented in both the larvae and adults, in populations from six states. Dyrkacz (1981. Recent instances of albinism in North American amphibians and reptiles. Society for the Study of Amphibians and Reptiles. 31 pp.) reported three larvae in Maryland and eight larvae in Mississippi.

FIG. 1. A) Albino gravid female *Ambystoma opacum* found in Franklin County, Tennessee. Note the complete lack of body pigmentation. B)Closeup of head showing red eyes.

Partial albinism in larvae has been documented in Rhode Island and Connecticut (Deegan et al. 1998. Herpetol. Rev. 29:229). Mitchell and Church (2002. Banisteria 20:67–69) collected two larval leucistic *A. opacum* in Virginia and stated this form of albinism rarely occurs in nature. Walston and Regester (2004. Herpetol. Rev. 35:365) reported partial albinism in larvae and a gravid female from a population in Illinois. A frequency of 0.24 for the occurrence of an albino phenotype was reported for the Illinois population (Walston and Regester 2004, *op. cit.*). I examined 9387 Marbled Salamanders at this wetland (5031 adults, 4356 metamorphs) between December 2007 and May 2010 and this was the only individual exhibiting any form of albinism, further illustrating the rarity in which albinism occurs in this species. To my knowledge, this is not only the first report of albinism in *A. opacum* for Tennessee, but also the first report range-wide of a complete albino gravid female.

I thank Brian Miller for comments on the manuscript and Robert English and Andrea English, Leaps, for allowing the use of their photographs.

JOSHUA R. CAMPBELL, Middle Tennessee State University, 1301 East Main Street, Murfreesboro, Tennessee 37132, USA; e-mail: jrc6t@mtsu.edu.

***EURYCEA BISLINEATA BISLINEATA* (Northern Two-lined Salamander). LARVAL PREDATION.** *Eurycea bislineata* is a semi-aquatic plethodontid salamander at the northeastern extreme of its geographic distribution in Québec and New Brunswick, Canada (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.). Terrestrial predators of both larval and adult *E. bislineata* include Common Garter Snakes (*Thamnophis sirtalis*) (Uhler et al. 1939. Trans. Fourth North American Wildlife Conference. Washington, D.C.). Spring salamanders (*Gyrinophilus porphyriticus*) are known to prey on larval *E. bislineata* (Wright and Haber 1922. Copeia 105:31–32; Bishop 1941. The Salamanders of New York. New York State Mus. Bull. 324), and Rainbow Trout have been observed feeding on *E. bislineata* (Mathews 1982. J. Tennessee Acad. Sci. 57:82–83).

American Eels (*Anguilla rostrata*) are known to be generalist predators, consuming a variety of aquatic invertebrates, insects, and small fish (Lookabaugh and Angermeier 1992. J. Freshwater Ecol. 7:425–431; Denoncourt and Stauffer. 1993 Am. Midl. Nat. 129:301–308; Daniels 1999. Diet of American Eels [*Anguilla rostrata* LeSueur] in Five Freshwater Lakes, Maine, USA. Ph.D. dissertation, Univ. Maine, Orono. 61 pp.); however, amphibians have not been observed in eel diets. Here we document the first reported incidence of eel predation on amphibians. One *E. bislineata* larva (32.5 mm TL, 17.1 mm SVL) was recovered undigested from the stomach of an American Eel (354 mm TL, 61.8 g) captured as bycatch from a Fisheries and Oceans Canada juvenile salmonid assessment on 20 Aug 2009 in the Nashwaaksis River, York County, New Brunswick, Canada (46.08059°N, 66.76832°W). The stomach of this eel contained only the *E. bislineata* larva. Identification was based on comparisons with collections in the New Brunswick Museum. The *E. bislineata* larva was deposited in the New Brunswick Museum (NBM 9142).

***TYLOTOTRITON ASPERRIMUS* (Black Knobby Newt). REPRODUCTION.** *Tylototriton asperrimus* is distributed in Central and South China, reaching the southwestern limit of its range in the northernmost provinces of Vietnam (Nguyen et al. 2009. Herpetofauna of Vietnam, Edition Chimaira, 768 pp.). Chinese literature (Fei [ed.] 1999. Atlas of Amphibians of China. Henan Science and Technology Press, Zhengzhou, China) reports clutches of 30–50 eggs, 3–4 mm in diameter, with light brown animal pole and creamy white vegetable pole, laid under fallen leaves on pond embankments some distance away from the water. The same literature refers to an aquatic phase of the adult salamanders, but reproductive activity has not been observed.

On 12 May 2010 we found an adult *T. asperrimus* (Fig. 1) 75 mm SVL, 145 mm total length, under a large rock in a marshy area where part of the forest was cleared at Pia Oac, SW of Tinh Tuc at 1596 m altitude, in the province of Cao Bang (22°60.556N, 105°87.530E) in northern Vietnam. Air temperature was 22–24°C, humidity 70–75%. Some 30 m further, by turning stones we discovered two assemblages of 123 total eggs, possibly representing two clutches. One assemblage was found in moist soil under a stone sticking out from the side of a forested slope (Fig. 2); the other was situated above the same stone, between the stone and adjacent undergrowth. The diameter of the egg capsule was 10–11 mm. Judging by the shape of the creamy white embryos in the transparent jelly capsules, we estimated the eggs were about one week old. The closest water body was a shallow (5–10 cm deep) puddle formed by rain water in a car track on a path, measuring 200 × 60 cm, water temperature was 17°C, pH 6.4, KH 0–3, GH <3. The stone was situated beside, and not directly above the puddle, on a slope overgrown with ferns and bamboo. On a vertical plane, one egg assemblage was some 20 cm removed from the level of the puddle, the other 50 cm. With the ensuing rainy season, the volume of the puddle would probably increase and rains would flush the emerging larvae from their capsules. NTT found 12 adult males, one female, and 24 larvae in the same puddle in early June

FIG. 1. Adult *Tylototriton asperrimus* found under a stone at Pia Oac, Cao Bang, Vietnam.

FIG. 2. Egg clutch of *Tylototriton asperrimus* found under a stone at Pia Oac, Cao Bang, Vietnam.

FIG. 4. Eggs and recently hatched larva of *Tylototriton asperrimus* from Pia Oac, Cao Bang, Vietnam.

2009, when the water level was higher (Fig. 3). Approximately 10 m further down there was a marshy area ca. 30 × 30 m with a small stream and several small pools with submerged and bordering vegetation. We did not find eggs, larvae, or adults there.

This discovery of eggs on land is comparable to an earlier find of *T. asperrimus* eggs on Mt. Tay Con Linh in Vi Xuyen district, Ha Giang province, Vietnam. Those eggs, believed to represent five clutches, were found 5 cm underground, adjacent to a small, temporary forest pool at 1700 m elev. (Bain and Nguyen 2004. Am. Mus. Novit. 3453:1–42).

We collected some of the eggs from the assemblage to study further development. On hatching the larvae measured 21–22 mm, had a long pigmented tail, no remains of yolk, no balancers, and four well-developed legs (Fig. 4). They were very agile and strong enough to actively flip from the spoon by which they were handled.

On the basis of a number of physiological and ecological similarities some authors have included *T. asperrimus* in the genus *Echinotriton* (Zhao and Hu 1988. Studies on Chinese Salamanders 12–26; Zhao and Adler 1993. Herpetology of China. Society for the Study of Amphibians and Reptiles, 522 pp.; Yu and Zhao 2005. Sichuan J. Zool. 24:646–650). One of these similarities is the laying of large eggs in one clutch on land, under a surface of fallen leaves. Larvae of *T. asperrimus* hatch at an advanced stage of development, and have resorbed the balancers, just like larvae of *E. chinhaiensis* (Cai and Fei 1984. Acta Herpetol. Sinica 3:71–78). Hatchling larvae of both *Echinotriton* species are known to migrate to the water body by making active leaping or wriggling movements (Utsunomiya et al. 1979. Proc. Japan Acad. 54[1978]:341–346; Xie et al. 2000. Herpetol. J. 10:111–118). We believe that hatchlings of *T. asperrimus* are capable of doing the same.

If adult *T. asperrimus* enter the water, it is difficult to imagine what else they would do there apart from breeding and/or foraging. *Echinotriton* species never enter the water. So in this respect *T. asperrimus* is more similar to other species of *Tylototriton*, which typically enter water for breeding. It looks like the reproductive mode of *T. asperrimus* is situated somewhere between that of other *Tylototriton* and *Echinotriton*. We anticipate that future observations will provide additional information.

ANURA — FROGS

***BUFO PUNCTATUS* (Red-spotted Toad) and *THAMNOPHIS CYRTOPSIS* (Black-necked Garter Snake). PREY-PREDATOR.** Several species of anurans breed in ephemeral rock pools in the American Southwest (Dayton and Fitzgerald 2001. Oecologia 129:430–435). These species breed explosively when ephemeral habitats fill and then rapidly complete development prior to pool drying. The advantage of breeding in ephemeral pools is that most aquatic predators require permanent water to complete their life cycle. However, predators that can effectively forage in ephemeral pools can potentially take advantage of an abundant food source.

On 3 July 1999, rock pools in Blackwater Canyon, Peloncillo Mountains, New Mexico, USA (31°30.465'N, 109°00.615'W, WGS84) filled overnight after a storm delivered 1.2 cm of rain. On 3 and 5 July we collected adult *Bufo punctatus* that had been preyed upon (or scavenged) by adult Sonoran Mud Turtles (Ligon and Stone 2003. Herpetol. Rev. 34:241–242), suggesting that breeding for this species began immediately after the pools filled. On 8 July 1999, we captured a juvenile *Thamnophis cyrtopsis* (165 mm SVL; 49 mm tail length; 3.0 g) in a rock pool. While we were examining the snake, it regurgitated 35 *B. punctatus* tadpoles, six of which were still alive. We collected 24 tadpoles, and assigned Gosner stages to 21 of these. The other tadpoles were too badly decomposed to collect or stage. Gosner stages ranged from 26–29 with a mode of 28 (N = 10 tadpoles), indicating that tadpoles were midway through development. The snake was measured and released, and the 24 tadpoles were deposited in the Herpetology Division of the University of Central Oklahoma Natural History Museum (UCO 803).

Thamnophis cyrtopsis is a well-known tadpole predator, and there are several observations of it preying on *B. punctatus* tadpoles (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman, Oklahoma. 332 pp.). Our observation adds to this database and provides a time frame

for the latency to response to the environmental cue (rainfall) that made the interaction possible.

We thank Mike O'Brien for field assistance and Erica Becker for assigning Gosner stages to the tadpoles. Fieldwork was conducted under permits issued by the New Mexico Department of Game and Fish and the U.S. Forest Service. The Office of Research and Grants at the University of Central Oklahoma provided financial support for fieldwork.

***CRAUGASTOR ALFREDI ALFREDI* (Northern Alfred's Rainfrog). PREDATION.** Because anurans often are locally abundant, small to moderate in size, and have soft skin, they are common prey for a variety of predators of all classes of vertebrates, as well as some arthropods. Various species of predaceous spiders feed on anurans (Menin et al. 2005. Phyllomedusa 4[1]:39–47). In some cases the frogs are caught in webs and subsequently killed and eaten, but crab spiders, tarantulas, and other hunting spiders spring on anuran prey, grasp them, and kill by injection.

On 11 Nov 2009, I found a partly-eaten *Craugastor alfredi alfredi* in Cañón del Metlac (18.9029°N, 97.0062°W, 800 m elev.), Ixtaczoquitlán, Veracruz, México. The frog was found on a banana tree leaf, and nearby was a female hunting spider, *Cupiennius salei* (species identification based on Benítez and Castañeda 1994. La Ciencia y El Hombre 16:37–48), which had partially consumed the frog. Because of the posture of the frog and the removed skin on the posterior part of the body, I suspect that it was attacked from behind. Photographs of the frog and the spider were deposited in the Colección de Anfibios y Reptiles, Facultad de Biología, Campus Peñuela, Universidad Veracruzana. The frog measured 46 mm SVL; cephalothorax to abdomen length of the spider was 44 mm. Identification of the frog was verified by Uri Omar García Vázquez.

***DUTTAPHRYNUS SCABER* (Ferguson's Toad). PREDATION BY BEETLES.** Invertebrate predation of vertebrates is widely known (Duellman and Trueb 1986. Biology of Amphibians. John Hopkins Univ. Press, Baltimore, 670 pp.). Beetle predators that specialize on vertebrates are uncommon (McCormick and Polis 1982. Biol. Rev. 57:29–58). Even rarer and little known are the beetle parasitoids of vertebrate hosts (Eggleton and Belshaw 1993. Biol. J. Linn. Soc. 48:213–226). Both adult and larval carabid beetles have been documented eating frogs (Littlejohn and Wainer 1978. Vict. Nat. 95:251–252; Ovaska and Smith 1988. Can. J. Zool. 66:599–604), but larvae in the carabid tribes Brachinini, Chlaeniini, Lebiini, and Peleciini exhibit more specialized predatory and parasitoid life cycles (Brandmayr et al. 2010. Zootaxa 2388:49–58; Erwin and Erwin 1976. Biotropica 8[4]:215–224; Frank et al. 2009. ZooKeys 14:1–36; Saska and Honek 2008. Ann. Entomol. Soc. Amer. 101[3]:533–538). The documented larvae of Peleciini and Lebiini are primarily ectoparasitic on chrysomelid beetle larvae and pupae, but a few non-chrysomelid hosts are known—other beetles (Dytiscidae, Endomychidae, and Hydrophilidae), mole crickets (Gryllotalpidae), and a millipede.

The documented chlaeniine larvae consume frogs and toads. Two blood-feeding carabid larvae were reported parasitizing a toad in South Africa (Moore 1971. Ann. Nat. Mus. 20:479–482). *Chlaenius darlingensis* Castelnau was reported as consuming *Crinia signifera* (Eastern Common Froglet) and *Uperoleia laevigata* (Smooth Toadlet) (Robertson 1989. Herpetol. Rev. 20:7–8; Toledo 2005. Herpetol. Rev. 36:395–400). Another chlaeniine, larvae of *Epomis nigricans* Wiedemann, was reported eating frogs: *Hyla* sp. and *Rhacophorus schlegelii* (Schlegel's Green Tree Frog) (Shiina and Tachikawa 1998. Abstracts 48th Ann. Meet. Entomol. Soc. Japan; Tachikawa 1994. Atlas 48th Spec. Exhib. Otaru Museum, Otaru), and both tadpoles and adults of *Pelophylax nigromaculatus* (= *Rana nigromaculata*; Toledo 2005. J. Zool. 271:170–177; Toshiaki 2006. Bull. Herpetol. Soc. Japan 2:99–100) in Japan. Elron et al. (2007. Herpetol. Rev. 38[1]:30–33) reported the biology of *Epomis dejeani* Dejean and *Epomis conscriptus* (Duftschmid) whose larvae attack adult frogs, *Pseudepidalea viridis* (= *Bufo viridis*; Green Toad) and *Hyla savignyi* (Yellow Lemon Tree frog), in Israel. Here we report another specialized carabid larval predator of an adult toad from India (Fig. 1).

The observation and photograph were made around 1000 h, 1 April 2008, near Karanji Lake, campus of the Regional Museum of Natural History, Mysore, Karnataka, India, 12°18.333'N, 76°40.45'E. The lawn was not well-maintained, and grasses and bushes along with scattered puddles provided good habitat for many insects. VB startled the toad, which appeared lean and jumped sluggishly; then he noticed the larva protruding from the abdomen. The photograph was taken but no specimens were collected. Kotambylu Vasudeva Gururaja, an expert on the regional herpetology at the Indian Institute of Science, Bangalore, identified the toad as *Duttaphrynus scaber*. *Duttaphrynus scaber* is found in India (Orissa State and southwards) and at lower elevations of Sri Lanka (view distribution at http://berkeleymapper.berkeley.edu/). CSC identified the larva as Carabidae based on her work with other carabid parasitoids of Chrysomelidae; given that only chlaeniines have been documented consuming frogs in this way, our larva is likely a chlaeniine but we cannot go further with an identification.

Elron et al. (2007, *op. cit.*) revealed that an individual *E. dejeani* larva may use up to four frogs to complete the life cycle; the 1st instar is ectoparasitic, feeding on body fluids, while the 2nd and 3rd instars chew body tissues. Toledo et al. (2005, *op. cit.*) termed this behavior "temporary specialized predators." It is a challenging question whether such specialized feeding represents an evolutionary step towards parasitoidism, in which one individual completes its life

FIG. 1. *Duttaphrynus scaber* from southern India with a carabid larva parasitoid embedded in the abdomen. Photo by V. Barve.

cycle on one host (Eggleton and Belshaw 1992. Phil. Trans. R. Soc. B 337:1–20).

We thank K. V. Gururaja for identification of the toad and C. D. Michener for comments on the manuscript.

VIJAY V. BARVE, Department of Geography, 1475 Jayhawk Blvd, 223 Lindley Hall, University of Kansas, Lawrence, Kansas 66045-7613, USA (e-mail: vijaybarve@ku.edu); **CAROLINE S. CHABOO**, Division of Entomology, Natural History Museum and Department of Ecology and Evolutionary Biology, 1501 Crestline Drive – Suite 140, University of Kansas, Lawrence, Kansas 66049-2811, USA (e-mail: cschaboo@ku.edu).

***ECNOMIOHYLA MIOTYMPANUM* (Small-eared Treefrog) and *CHARADRAHYLA TAENIOPUS* (Porthole Treefrog). REPRODUCTIVE BEHAVIOR.** *Ecnomiohyla miotympanum* and *Charadrahyla taeniopus* are endemic to the Atlantic Versant in the Sierra Madre Oriental of México (Duellman 2001. The Hylid Frogs of Middle America. Society for the Study of Amphibians and Reptiles, in cooperation with the Natural History Museum of the University of Kansas. 1170 pp.). Male *E. miotympanum* reach 38.4 mm SVL, and attract females by means of an advertisement call, whereas acoustic communication for mate acquisition in *C. taeniopus* (whose females are 70 mm SVL) does not seem to be important (Duellman 2001, *op. cit.*). Despite these differences in size and presumably in reproductive behavior, here we report an observation of amplexus between these two hylid frogs.

On 30 Oct 2009, we surveyed anurans along the Apulco River (19°57'N, 97°32'W; 1041 m elev.), located in the Sierra Norte of Puebla, México. At 0008 h, one of us (FGVC) found a male *E. miotympanum* in amplexus with a female *C. taeniopus*, on a stone at the river's edge (Fig. 1). Although the couple was manipulated, they remained in amplexus during the observation period which lasted for at least 23 min. We cannot be certain how long the frogs remained in amplexus after our observations. This kind of interspecies interaction may increase the risk of predation, and implies an unsuccessful time investment that otherwise could be utilized for mating with conspecific individuals (Butler 2007. Herpetol. Rev. 38:444; Höbel 2005. Herpetol. Rev. 36:55–56). Indeed, if gamete release occurred, it would mean a considerable loss of energy, at least for the female.

RICARDO LURÍA MANZANO (e-mail: doumbek@hotmail.com) and **FLOR GABRIELA VÁZQUEZ CORZAS**, Laboratorio de Herpetología, Escuela de Biología, Benemérita Universidad Autónoma de Puebla, C.P. 72570, Puebla, México.

FIG. 1. Male *Ecnomiohyla miotympanum* in amplexus with a female *Charadrahyla taeniopus* found in the Sierra Norte of Puebla, México.

***ENGYSTOMOPS PUSTULOSUS* (Tungara Frog). PREDATION.** On 1 Aug 2010 at 2000 h local time, at Parque Nacional Palo Verde, Provincia Guanacaste, Costa Rica (10.34459°N 85.34080°W), we observed a large belostomatid (giant water bug) predating an adult male *Engystomops pustulosus* (Fig. 1). This took place in a flooded roadside ditch, in close proximity to several calling male *E. pustulosus*. We did not observe the bug seize the frog, but the frog appeared fresh and alive (though not moving), and was presumed to have been recently captured. As we photographed the bug, it swam away with the frog still in its grasp, and we presume that it consumed the frog. Belostomatids are among the most common invertebrate predators of frogs, and the ecologically similar *Physalaemus cuvieri* has been observed to fall prey to these insects (Toledo 2005. Herpetol. Rev. 36:395–400). However, this is the first observation of predation of *E. pustulosus* by a belostomatid. Two species of *Lethocerus* are reported from Costa Rica: *L. medius* (Guérin-Méneville) and *L. collosicus* (Stål) (Perez-Goodwyn 2006. Stutt. Beiträge zur Natur. 695:1–71). The belostomatid reported here was large (> 8 cm), and well outside the reported geographic range of *L. medius*. Because of its size and the geographic region, the tentative identification of this insect is *L. collosicus*.

FIG. 1. Belostomatid (likely *Lethocerus collosicus*) predating *Engystomops pustulosus*.

We thank Christiane Weirauch (University of California, Riverside) for additional bug identification consultation for this note. This observation was made under RESOLUCIÓN No 018-2009-ACAT (MINAET, Ministry of Environment, Energy, and Telecomunications) while conducting research funded by the NSF IRES grant to the Organization for Tropical Studies.

***HYLA CINEREA* (Green Treefrog). WINTER AGGREGATION.** Hibernation site selection is poorly known for adult North American treefrogs, and true winter aggregation has not been reported. Here, I report a winter aggregation of *Hyla cinerea* in southern Louisiana, USA.

At 1230 h on 28 Dec 2009, I discovered 31 adult-sized *H. cinerea* between two 0.5 × 61 × 244 cm plywood boards (air temperature

TABLE 1. Hibernation sites for adult North American treefrogs (*Hyla* and *Pseudacris*). In the "N" column, groups of individuals found together are separated by a comma.

5.3°C). The boards were among ~20 others in a pile stored ~1 m above the ground, under the west side a house that was elevated 4 m on pilings. Natural ground elevation was ~0.5 m, thus the frogs' refuge was ~1.5 m above sea level, in an area largely surrounded by brackish marsh and open waterways. The pile of boards had been in the weather for at least 6 months, and had warped to form ~1 cm crevices between them. The frogs were initially clustered next to each other in a roughly oval shape between the boards. Within three minutes of removing the board hiding them, all of the frogs had crawled slowly until each fell off the edge onto the ground, and continued to disperse into vegetation. The site was located at 30.303427°N, 90.330054°W, just south of the Joyce Wildlife Management area, ca. 8 air km E of the village of Manchac, Louisiana, USA.

Table 1 summarizes reported hibernation sites, most of which represent only one locality within each species' geographic range. Note that each account includes <5 individuals. Habitat descriptions in the Table 1 references suggest that many species move to different habitat for winter hibernation sites. Some of these sites were at higher elevation and may be above flood level, particularly in canyon habitat that may be prone to seasonal flooding. The present report is of a remote location in brackish marsh that potentially experiences flooding and increased salinity by wind-driven tides through Lake Pontchartrain. Variation in elevation in most of this marsh is less than 1m, such that sustained light east wind for 2–3 days would likely flood most of the area. Historical floods levels in the local area suggest that the frogs would have been above most flooding associated with normal weather patterns, but not catastrophic floods like those produced by organized storms (i.e., tropical depressions, tropical storms, hurricanes), which do not normally occur there during winter. Thus, a potential explanation for the unusually large aggregation of frogs reported here is that suitable hibernation sites above flood level are rare in the area. Alternatively, and perhaps in addition, a frog aggregation may reduce evaporative water loss by reducing the amount of exposed body surface area.

CLIFFORD L. FONTENOT, JR., Department of Biological Sciences, Southeastern Louisiana University, Hammond, Louisiana 70402, USA; e-mail: cfontenot@selu.edu.

***HYLA CINEREA* (Green Treefrog). CANNIBALISM AND DEFENSIVE POSTURE.** Cannibalism among larval amphibians is not unusual (Pfennig et al. 1993. Anim. Behav. 46:87–94; Poelman and Dicke 2007. Evol. Ecol. 21[2]:215–227), and adults of large anuran species like Cane Toads (*Rhinella marina*) are also known to prey on smaller anuran species or smaller conspecifics (Pizzatto and Shine 2008. Behav. Ecol. Sociobiol. 63[1]:123–133). However, reports of adult treefrogs cannibalizing smaller conspecifics are rare (McCallum et al. 2001. Herpetol. Rev. 32[2]:99–100), and to my knowledge there has never been a report of a Green Treefrog consuming a smaller conspecific.

Here I report an incident of cannibalism of a recently metamorphosed *Hyla cinerea* (20.7 mm SVL) by an adult, male *H. cinerea* (41.6 mm SVL) (Fig. 1), which occurred on 23 June 2009 at a pond

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Adult male Green Tree Frog (*Hyla cinerea*) consuming a recently metamorphosed conspecific. Inset: Semicircular scars left on back of juvenile.

at Bowens Mill Fish Hatchery in Georgia, USA. I observed the frogs from when the male had apparently just captured the juvenile (only the juvenile's head was inside the male's mouth), until he had largely swallowed it (only one hind leg protruded out of the mouth). *Hyla cinerea* consume a variety of invertebrate prey, including insects and spiders of similar size to those of recently metamorphosed conspecifics. At the time the cannibalistic behavior occurred, recently metamorphosed frogs were relatively abundant at the site, and could thus provide a readily available food source for appropriately sized adults.

During the process of being preyed on, the juvenile struggled and showed defensive posturing which included spreading and locking of arms and legs. Although these defensive postures did not deter further ingestion, they seemed to interfere with the predator's ability to swallow its prey. It took the male more than 15 minutes to proceed beyond the outstretched arms of the juvenile, and another15 min to swallow it to the point where only one leg protruded from its mouth. After more than 30 min of observation I captured the male to document its size, at which point he regurgitated its prey. Without this intervention, it is certain the juvenile would have been fully consumed. The juvenile was still alive, but showed a series of semicircular scars across its back (Fig. 1-inset). Both frogs were released at the site of capture immediately after size measurements were taken.

GERLINDE HÖBEL, University of Wisconsin-Milwaukee, Department of Biological Sciences, Lapham Hall, Milwaukee, Wisconsin 53201, USA; e-mail: hoebel@uwm.edu.

***HYLA INTERMEDIA* (Italian Treefrog). CANNIBALISM.** Cannibalism often occurs in crowded conditions where resources are limited (Crump 1983. Amer. Nat. 121[2]:281–289) and the predator benefits from a gain in nutrients, a reduction in competition for food, and consequently increased fitness. Amphibians breeding in ephemeral pools are especially likely to experience crowding and food limitation as the pond dries, leading to intraspecific predation (Crump 1983, *op. cit.*; Crump 1990. Copeia 1990:560–564; Jordan et al. 2004. Western N. Amer. Nat. 64[3]:403–405). As a temporary pond dries, larvae are subject to intensifying pressure for oxygen, food, space, and there is also a build-up of waste products, which can lead to intra-larval competition and inhibition of growth of some larvae (Kovaks and Sas 2009. North-West. J. Zool. 5[1]:206–208). In such pond drying situations, larger larvae may prey on smaller conspecifics (Kovaks and Sas 2009, *op. cit.*).

We observed the larvae of the prolonged breeding anuran, *Hyla intermedia*, in an ephemeral pool formed by rainwater collecting in the tire tracks of agricultural vehicles. The pool was located near San Ruffino Lake, Le Marche, Italy (43.0011°N, 13.3844°C). Observations at the breeding pool were made daily from 16 May to 13 June 2010 but the time of day at which observations were made varied. Two cohorts of larvae hatched in the pool during the study period. Spawn was laid on 17 May and 24 May. The first cohort hatched on 24 May and the second on 30 May. This indicates a developmental time to hatching of 7 and 5 days, with the increased developmental time of the second cohort probably reflecting the increasing temperature of the pool. This agrees with the observations of Sayim and Kaya (2008. Biologia 63[4]:588–593) who observed hatching after 5 or 6 days in the laboratory at 20°C in the closely related species *Hyla arborea*. The different cohorts were easily distinguished by their size and development stage. Early developmental stages were determined by comparing to those shown in Sayim and Kaya (2008, *op. cit.*).

The pond dried steadily over the course of the study and by 13 June there was <1 cm of water left and between 12 June and 13 June the younger larvae were no longer visible in the pool. There are several possible reasons for this. Small larvae may have burrowed into the mud at the bottom of the pool, but this is unlikely due to the probable low O_2 levels as the pond dried. Alternatively, larvae may have died due to a build-up of waste products, low O_2 levels, or lack of food. However no remains were seen and we think that this would have been unlikely to affect all larvae simultaneously.

The most likely explanation is that the smaller larvae were consumed by their larger conspecifics as an response to the drying up of a small, ephemeral pool, a condition in which cannibalism is likely to be common (Hoff et al. 1999. *In* R. W. McDiarmid and R. Altig [eds.], Tadpoles. The Biology of Anuran Larvae, pp. 215–239. Univ. Chicago Press, Chicago, Illinois). Unfortunately, we were not able to compare the responses of larvae in a non-ephemeral pool. To our knowledge this is the first time that cannibalism has been reported in *Hyla intermedia* tadpoles.

RACHEL GRANT, Department of Life Sciences, The Open University, Milton Keynes, MK7 6BJ, United Kingdom (e-mail: Rachelannegrant@gmail.com); **TIM HALLIDAY**, 21 Farndon Road, Oxford, OX2 6RT, United Kingdom.

***HYPSIBOAS RANICEPS* (Chaco Treefrog). PREDATION.** Anurans are potential prey to all classes of vertebrates, many invertebrates, and even carnivorous plants (Andrade-de-Figueiredo et al. 2010. Herpetol. Notes 3:053–054; Ghizoni-Jr et al. 2000. Melopsittacus 3[3]:137–139; Morais et al. 2010. Herpetol. Rev. 41[3]:336; Pombal 2007. Rev. Bras. Zool. 24[3]:841–843). Studies on the predation of amphibians are sparse and are based mostly on fortuitous observations. This is due to the difficulty of observation and quantification of predation events, but it has been estimated that such events occur frequently (Pombal 2007, *op. cit.*).

Hypsiboas raniceps is a medium-sized hylid commonly found in Brazilian Cerrado, Atlantic Rainforest, and Caatinga biomes (Arzabe 1999. Ver. Bras. Zool. 16[3]:851–864; Guimarães et al. 2003. Iheringia 93[2]:149–158). They occur in Amazonian Colombia, Venezuela (Amazonas), French Guiana, eastern Brazil, Paraguay, northern Argentina, and eastern Bolivia (Frost 2010. Amphibian Species of the World: an Online Reference. Version 5.4 [8 April 2010]. Electronic database accessible at http://research.amnh.org/vz/herpetology/amphibia/. American Museum of Natural History, New York. Accessed 14 Sept 2010).

FIG. 1. Adult male *Leptodactylus latrans* predating an adult male *Hypsiboas raniceps*.

Leptodactylus latrans is also a medium-sized anuran with a wide distribution in South America, occurring in Paraguay, Argentina, Uruguay, and practically all of the Brazilian territory (Oliveira et al. 2009. Biodivers. Pampeana 7[1]:44–46).

On 29 Aug 2010 at 1930 h an adult male *L. latrans* (81.6 mm SVL) was observed predating an adult male *H. raniceps* (72.3 mm SVL) (Fig. 1). The observation occurred 6 m from the margin of a temporary pond at the U.C. Refuge for Wildlife Mata do Junco (10.291037°S, 36.583701°W, 120 m elev.), in the city of Capela, Sergipe, Brazil. The anurans are deposited in the Herpetological Collection of the Federal University of Sergipe (CHUFS C0607, C0608). *Leptodactylus* spp. are well known predators of small anurans (Haddad and Sazima 1992. Unicamp. FAPESP. 321 pp.), and may contribute significantly to the anuran community structure in this region.

ANTHONY SANTANA FERREIRA (e-mail: anthonyyferreira@hotmail.com), **RENATO GOMES FARIA**, **IZABEL REGINA SOARES DA SILVA**, and **SOFIA CERQUEIRA SCHETTINO**, Laboratório de Herpetologia, Universidade Federal de Sergipe, CEP 49000-000, São Cristovão, Aracaju, Sergipe, Brazil.

***INDIRANA SEMIPALMATA* (Brown Leaping Frog). REPRODUCTION.** The ranid frog genus *Indirana* contains 11 species, all of which are endemic to the Western Ghats Mountains of southern India. Limited information is available regarding the breeding biology of this genus other than anecdotal notes, mostly about the most widespread species, *I. beddomii* (Daniels 2002. The Book on Indian Reptiles and Amphibians. Bombay Nat. Hist. Soc., Oxford Press, Mumbai, India. 238 pp.; Daniels 2005. Amphibians of Peninsular India. Universities Press India: Hyderabad 268 pp.; Das and Dutta 2007. Hamadryad 31:152; Inger et al. 1984. J Bombay Nat. Hist. Soc. 81[2]:406; Roelants et al. 2004. Mol. Phyl. Evol. 31:730), all of which remark that *Indirana* breed on rock faces in the immediate surroundings of splashing water. The semi-terrestrial tadpoles of *I. beddomii* are morphologically specialized with strongly hooked beaks and a long, strongly developed tail with reduced fin membranes which allow the tadpoles to skip across the rock surfaces on which they feed (Bossuyt and Milinkovitch 2000. PNAS 97:6585; Kuramoto and Joshy 2002. Hamadryad 27:71). *Indirana semipalmata* is a rarely encountered species, the life history of which is unknown, except for a study on its tadpoles by Kuromoto and Joshy (2002, *op. cit.*). Herein we report observations of egg laying sites of *I. semipalmata*.

Observations were made during the southwest monsoons, in the month of July at the Agumbe Rainforest Research Station (ARRS),

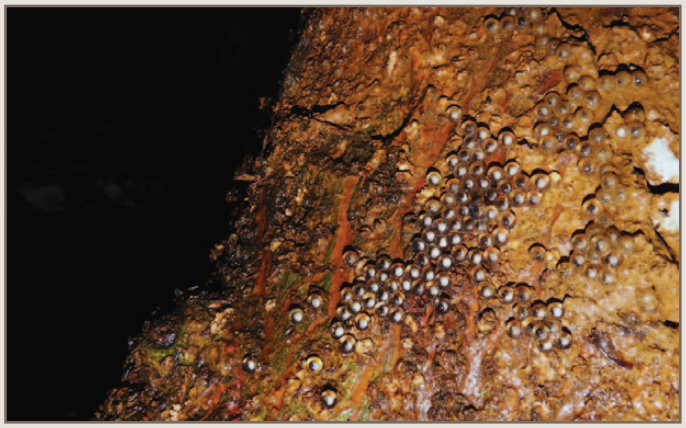

FIG. 1. Egg clutch of *Indirana semipalmata* on the bark of *Erythrina variegata*.

FIG. 2. Tadpole of *Indirana semipalmata* feeding on the bark of *Erythrina variegata*.

Agumbe, Shivamogga District, Karnataka, India (13°N, 75°E, 600–700 m elev). ARRS is a 3.2-ha area consisting of a Betel Nut (*Areca catechu*) plantation and fallow paddy fields bordered by secondary tropical rainforest. Temperature ranges between 10–35°C and average annual rainfall is ca. 7000 mm/yr. Three egg clutches were observed. The eggs were attributed to *I. semipalmata* because adult male frogs were observed sitting alongside possibly guarding the eggs. When the eggs hatched the tadpoles were similar to those of *I. beddomii* "with strongly hooked beaks and a long strongly developed tail with reduced fin membranes" (Kuramoto and Joshy 2002, *op. cit.*). The first egg clutch was observed on 7 July 2010 on the concrete steps of a bungalow located in a Betel Nut plantation. The eggs were laid 68 cm above the ground in a film of water that accumulated from water splashing as it ran from the roof tiles onto the concrete area below the steps. Clutch size was 343 eggs and average egg diameter 2.7 mm. The eggs hatched on 11 July 2010. Tadpoles remained on the concrete surface feeding post hatching.

The second egg clutch was observed on 15 July in a metal dish that had been left on a granite slab which formed the seat of a bench 47 cm off the ground. This granite bench was also situated in the Betel Nut plantation. Clutch size was not determined as the eggs were at different stages of development and inferred to represent multiple clutches. Tadpoles remained on the granite surface post hatching and were observed feeding. The third egg clutch was first observed on 15 July under a piece of wood propped up against the bark of an Indian Coral Tree (*Erythrina variegata)* at the edge of the Betel Nut plantation (Fig. 1). The eggs were laid 75 cm above the ground and the clutch size was 143 eggs with an average egg diameter of 2.9 mm. Eggs began hatching on 19 July. During the day one tadpole with hind limbs (therefore from an earlier clutch) was observed feeding on the bark surface of this tree, indicating that tadpoles remain on the tree once they have hatched (Fig. 2). It was notable that there were no pools of standing water within 3 m of any of the egg deposition sites mentioned.

These observations indicate that the eggs of *I. semipalmata* are laid, develop, and hatch outside of standing water. This differs from previously published accounts (Daniel 2002, *op. cit.*; Daniels 2005, *op. cit.*; Inger et al. 1984, *op. cit.*; Kuramoto and Joshy 2002, *op. cit.*) for other species of this genus. In each of the cases the eggs were hydrated when water was splashed upon them, when it dripped from the leaves or roof tiles above or ran down the branch upon which the eggs were laid. As far as we are aware, this is the first known case where tadpoles have been observed feeding on a bark substrate and subsequently metamorphosing on the bark of a tree. Given that there is such high rainfall in Agumbe, an adaptation where eggs are able to develop out of water may be a localized phenomenon. To determine if this is a viable life history strategy elsewhere would require further study in the Western Ghats.

The highly specialized, semi-terrestrial tadpole of *Indirana* is restricted to the Western Ghats by ecogeographical barriers (Roelants et al. 2004, *op. cit.*). The specialized life history of *I. semipalmata* described here makes them vulnerable to changes in rainfall pattern/climate and at the mercy of the monsoon.

***LEPTODACTYLUS FUSCUS* (Whistling Frog). HABITAT AND DIET.** *Leptodactylus fuscus* is widely distributed in South America east of the Andes, between Panama and northern Argentina, and is found in open fields, pastures, marshes, degraded forests, and urban habitats (Reynolds et al. 2004. *In* IUCN Red List of Threatened Species. Version 2010.1. <www.iucnredlist.org>. Downloaded 01 June 2010). Here we report on the occurrence of the species in mangrove forests, where the abundant invertebrate fauna is likely an important alimentary resource.

Leptodactylus fuscus is a "sit-and-wait" forager (Perry and Pianka 1997. Trends Ecol. Evol. 12:360–384), which typically feeds on small arthropods, principally Isoptera and Coleoptera, as well as insect larvae (De-Carvalho et al. 2008. Biota Neotropical 18:105–115). Between April 2008 and May 2009, 30 *L. fuscus* (7 males, 10 females, and 13 juveniles) were recorded on the Bragança Peninsula in the Brazilian state of Pará. The local mangrove forests cover a total area of ca. 467 km² of mudflats, and are dominated by tree species of the genera *Avicennia* and *Rhizophora* (Souza-Filho and El-Robrini 1996. Geonomos 4:1–16).

FIG. 1. Capture of a crab of the genus *Uca* by *Leptodactylus fuscus* in the mangrove forest on the Bragança Peninsula, Pará, Brazil. Photo by R. P. Silva.

The analysis of stomach contents (males: 52.1 mm SVL, females: 47.3 mm SVL, and juveniles: 39.4 mm SVL) revealed a predominance of arthropods in the diet (Formicidae – 35.2%, Acari – 16.0%, insect larvae – 10.3%, and Coleoptera – 9.8%), as well as a crab of the species *Pachygrapsus gracilis* (Crustacea: Decapoda). The observation of the capture of a crab of the genus *Uca* by a Whistling Frog (Fig. 1) further reinforces the ability of the species to adapt to the diversity of habitats and resources available within its broad geographic distribution. The exploitation of a wide range of invertebrate prey and the occupation of the mangrove ecosystem, which is relatively inhospitable for the majority of ectothermic vertebrates, appears to represent an advantageous adaptive strategy for *L. fuscus*, in particular by reducing competition with other organisms, including anurans, that compete for more typical resources in shared habitats.

FERNANDES** (e-mail: mebf@ufpa.br), Laboratório de Ecologia de Manguezal, Instituto de Estudos Costeiros, Campus de Bragança, Universidade Federal do Pará, Al. Leandro Ribeiro s/n, Bragança, 68.600-000, Pará, Brazil.

***LEPTODACTYLUS LATRANS* (Butter Frog). DIET.** *Leptodactylus latrans* is a large nocturnal frog that is widely distributed throughout South America east of the Andes (Frost 2010. Amphibian Species of the World: an Online Reference. Version 5.4 [8 April 2010]. Electronic database accessible at http://research.amnh.org/vz/herpetology/amphibia/). The species inhabits natural environments such as ponds, rivers, and lakes as well as urban areas. Ferreira and Tonini (2010. Herpetol. Notes 3:237–238) reported *L. latrans* occupying crab burrows in a mangrove ecosystem, which was the first report of a frog living in this type of habitat. The generalist diet of *L. latrans* is well known (França et al. 2004. Stud. Neotrop. Fauna Environ. 39:243–248; Sanabria et al. 2005. Rev. Peruana Biol. 12:472–477; Solé et al. 2009. Herpetol. Notes 2:9–15; Strussman et al. 1984. J. Herpetol. 18:138–146; Teixeira and Vrcibradic 2003. Cuad. Herpetol. 17:113–120). *Leptodactylus latrans* feeds on a variety of

invertebrates and small vertebrates, including anurans and fish (Teixeira and Vrcibradic, *op. cit.*; Teixeira et al. 2010. Herpetol. Bull. 112:41–42). Solé et al. (2009, *op. cit.*), studying a population of *L. latrans* at a Cacao plantation, reported the first decapod crustacean in the diet of *L. latrans*. In March 2005, in the mangrove ecosystem of the Federal University of Espirito Santo (20.2667°S, 40.3°W), an urban area of the municipality of Vitoria, southeastern Brazil, RBF observed a female (8.42 cm SVL; 92.6 g) *L. latrans* eating a juvenile Mangrove Crab. This frog was captured and brought to the laboratory for further examination. An examination of the stomach contents revealed two coleopteran larvae, one lepidopteran larva, one orthopteran, and one Araneae in addition to the crab. This is the first published report of *L. latrans* eating a mangrove crab.

***LITHOBATES CATESBEIANUS* (American Bullfrog). PREDATION.** Great Blue Herons (*Ardea herodias*) commonly prey on anurans (Butler 1997. The Great Blue Heron: A Natural History and Ecology of a Seashore Sentinel. UBC Press, Vancouver, British Columbia) and frequently have been photographed eating bullfrogs (e.g., http://www.whatbird.com/forums/forums/thread/114157.aspx). On several occasions between April and June 2010, in a newly mitigated (100 m^2) wetland in Hancock County, northwest Ohio, USA (40.9905°N, 83.7596°W), we observed *A. herodias* stalking and eating frogs, many of which we tagged with transponders (Biomark Inc., TXP148511B**,** 8.5 mm × 2.12 mm, 134.2kHz ISO, 0.067 g). On 27 Aug 2010, we located a patch of forested land with heron nests in three ca. 30 m tall sycamore trees (40.9849°N, 83.6904°W), the tallest trees in the woodlot, 5.87 km from the aforementioned wetland. Although the birds vacated the site at the end of July 2010, patches of heron droppings were visible on the ground around some trees. A search directly under the nests with a Pocket Reader (Biomark Inc.) revealed a transponder that was placed in an American Bullfrog tadpole (95 mm total length) on 11 April 2010. The transponder was located about 1 cm below a ground litter of fragmented tree bark, twigs, and dried leaves. A frog clavicle was found 10 cm from the transponder. To our knowledge this is the first reported incidence of predation on frogs by herons in which the feeding habitat and the nesting site were determined by recovering a transponder from the remains of a defecated (or regurgitated) bullfrog.

JILL A. DENTEL, ALEX REIST, OLIVIA HORNACEK, JESSICA McBRIDE, CHRIS WHITE, and **TERRY D. SCHWANER,** College of Sciences, The University of Findlay, 1000 North Main Street, Findlay, Ohio 45840, USA (e-mail: schwaner@findlay.edu); **JIM SPURGAT,** 6781 Country Road 26, Rawson, Ohio 45881-9731, USA.

***ODONTOPHRYNUS MAISUMA* (NCN). CANNIBALISM.** *Odontophrynus maisuma*, Cycloramphidae, is a fossorial frog that was recently described as a new species distinct from populations of *O. americanus* (Rosset 2008. J. Herpetol. 42:135). This species occurs on the coast of southern Brazil and Uruguay and is associated with wet environments and open grasslands (Achaval and Olmos 2003. Anfíbios y Reptiles del Uruguay. Graphis Impresora, Montevideo, Uruguay. 136 pp.). On 14 May 2009 at 0900 h, we collected a female *O. maisuma* (35 mm SVL; 7.0 g) in a pitfall trap that contained a juvenile *O. maisuma* (23 mm SVL; 0.3 g) in her stomach. The capture was made in wetland habitat associated with coastal sand dunes (32.1654°S, 52.1523°W, datum Corrego Alegre, sea level) in municipality of Rio Grande, RS, southern Brazil. The bucket in which the individual was captured was relatively large (40 cm diameter) and the individual remained in the trap for no more than 12 h, which perhaps reduced the possibility that the cannibalism occurred due to stress. Moreover, the bucket contained numerous arthropods that could be utilized as a food source. Records of cannibalism are rare among post-metamorphosed anurans, and this is the first report for the family Cycloramphidae. The lack of dietary studies of *O. maisuma* increases the importance of this information for understanding the feeding habits of the species. The anurans collected were deposited in the Collection of the Laboratório de Ecologia de Vertebrados Terrestres of FURG (AMRG48; AMRG49). We thank CNPq and Fapergs for financial support and ICMBio for collecting permits.

***OLLOTIS ALVARIA* (Sonoran Desert Toad). REPRODUCTION.** Adult male anurans have been known to attempt amplexus with conspecific females and males, both sexes of other species of anurans and even inanimate objects. Streicher (2008. Herpetol. Rev. 39:75) provided a photograph of an adult male American Toad (*Anaxyrus americanus*) in amplexus with a tennis ball for ca. 2 min. in Fairfax County, Virginia. We provide observations and a photograph of an adult male Sonoran Desert Toad (*Ollotis alvaria*) discovered in amplexus with a non-native adult male American Bullfrog (*Lithobates catesbeianus*).

At 2200 h on 19 July 2008, CBG and M. Davis discovered a large adult male *O. alvaria* in amplexus with a similar-sized adult male *L. catesbeianus* (Fig. 1) on the sandy margin of the Santa Maria River, ca. 12 km SE of Bagdad, Yavapai County, Arizona (USA) (34.484722°N, 113.055125°W; 712 m elev.). These male anurans remained in amplexus and did not move from their position during the ca. 5 min they were observed and photographed. The surrounding soil was very damp due to heavy rain during the previous night.

FIG. 1. Adult male *Ollotis alvaria* in amplexus with an adult male *Lithobates catesbeianus*. Photo by Charles Grogan.

CHARLES B. GROGAN, 65 Pine Ridge Road, Flagstaff, Arizona 86001, USA (e-mail: cgrog@earthlink.net); **WILLIAM L. GROGAN, JR.**, Florida State Collection of Arthropods, Florida Department of Agriculture and Consumer Services, Gainesville, Florida 32614, USA (e-mail: groganw@doacs.state.fl.us).

***OOPHAGA PUMILIO* (Strawberry Dart Frog). HABITAT USE.** *Oophaga pumilio* occurs in lowland rainforests from Nicaragua to Panama. In these habitats, they typically will utilize the forest floor for foraging as well as defending territories. After eggs hatch in the leaf litter, the female will transport the larvae to arboreal water sources such as bromeliads (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). Previous research has shown that *O. pumilio* will travel up to 12 m into a tree to deposit tadpoles (Young 1979. Biotropica 11:238–239). Here, I report the distance frogs will travel is far greater and that frogs are likely establishing territories in the canopy as well as on the forest floor.

In June 2010 on Isla Colon, Bocas del Toro, Panama, I ascended into the canopy of a *Ficus* sp. to 30 m and observed an *O. pumilio* on a branch next to the climbing line. This frog examined a small bromeliad before continuing to climb up the branch higher into the canopy. In August 2009, I ascended a different tree to 40 m and heard the advertisement call of a male in the tree next to the one I was climbing which was approximately at my level. Further, on both excursions, males could be heard through the entire ascent although height of males could not be determined. Other individuals have been seen as high as 46 m into the canopy (J. Maher, pers. comm.). As advertisement calls vary significantly from aggressive calls in this species (Bunnell 1973. Copeia 1973:277–284), frogs heard calling in the canopy presumably were calling to establish a territory and attract mates.

Utilization of canopy resources may be more important to *O. pumilio* than previously thought. Virtually all previous research on this species has taken place at ground level; thus future studies on populations and ecology of *O. pumilio* should include a canopy component to better understand habitat use of this species.

J. P. LAWRENCE, Department of Fisheries and Wildlife, Michigan State University, East Lansing, Michigan 48824, USA; e-mail: lawre161@msu.edu.

***OSTEOPILUS SEPTENTRIONALIS* (Cuban Treefrog). PREY.** *Osteopilus septentrionalis* is native to Cuba, Cayman Islands, and Bahamas (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida. 155 pp.), and has been introduced into five states in the USA, but is established only in Florida (Barbour 1931. Copeia 1931:140; Crother 2008. Scientific and Standard English Names of Amphibians and Reptiles of North America. SSAR Herpetol. Circ. 37, 84 pp.). In Florida, *O. septentrionalis* is known to prey primarily on roaches (Dictyoptera), but has also been documented consuming lizards (anoles and geckos), frogs (including its own species) (Meshaka et al. 2004, *op. cit.*), native Florida Brown Snake (*Storeria victa*) (Maskell et al. 2003. Herpetol. Rev. 34:137) and Ring-necked Snake (*Diadophis punctatus*) (Krysko and Halvorson 2010. Herpetol. Rev. 41:339–340) in Florida. Herein, we report *O. septentrionalis* preying upon a native Florida Striped Scorpion (*Centruroides hentzi*) in Florida.

On 2 Oct 2010 at 945 h, an *Osteopilus septentrionalis* (ca. 49.5 mm SVL) was collected at the Natural Area Teaching Laboratory, Univ. Florida campus, Gainesville, Alachua Co. (29.63384°N, 82.36851°W, WGS84; elev. 26 m) inside a vertical PVC pipe set up to sample treefrogs. This nonindigenous *O. septentrionalis* was deposited in the Florida Museum of Natural History (UF 160926), dissected and found to contain a native Florida Striped Scorpion (*C. hentzi*) (34.5 mm total length) in its stomach. This is the first known record of this nonindigenous frog preying upon a native scorpion in Florida.

We thank Walter E. Meshaka, Jr. for information.

MICHAEL C. GRANATOSKY, LINDSAY M. WAGNER, and **KENNETH L. KRYSKO**, Florida Museum of Natural History, Division of Herpetology, P.O. Box 117800, University of Florida, Gainesville, Florida 32611, USA (e-mail: mgranato@ufl.edu).

***PSEUDIS PLATENSIS* (Paradox Frog). PREDATION.** Amphibians are common prey for a great variety of vertebrates, arthropods, and even carnivorous plants (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York. 670 pp.; Pough et al. 1998. Herpetology. Prentice-Hall, New Jersey. 577 pp.). *Pseudis platensis* is reported to be preyed upon by *Caiman yacare* (Santos et al. 1996. Herpetol. J. 6:111–117) and the Rufescent Tiger Heron (*Tigrisoma lineatum*) (Prado 2003. Herpetol. Rev. 34:231–232). Predation of anurans by birds is considered to be occasional and opportunistic (Toledo et al. 2007. J. Zool. 271:170–177). Predation of anurans by the Guira Cuckoo (*Guira guira*) is rare and limited to three reports; *Physalaemus* cf. *fuscomaculatus* (Kokubum and Zacca 2003. Herpetol. Rev. 34:232–233), *Leptodactylus ocellatus* (Repenning et al. 2009. Zoologia 26:443–453), and *Rhinella granulosa* (Mesquita 2009. Rev. Bras. Ornit. 17:84–85). Herein we report the predation of adult *Pseudis platensis* by a group of Guira Cuckoos.

On 17 Sept 2010 at 0900 h, on the margin of a pond in the municipality of Bataiporã, Mato Grosso do Sul State, Brazil (22.51645°S, 53.28405°W, SAD 69), four events of *P. platensis* predation by *G. guira* were observed (Fig. 1). This is the first record of an aquatic anuran being preyed upon by the Guira Cuckoo; individuals captured were swallowed whole. The diet of the Guira Cuckoo is made up mostly of arthropods (Schubart et al. 1965. Arq. Zool. 12:95–249), especially Orthoptera (Repenning et al. 2009, *op. cit.*). The abundance of *P. platensis* in the study area is high, so predation by the Guira Cuckoo can be considered opportunistic.

FIG. 1. *Pseudis platensis* being preyed on by *Guira guira* in Bataiporã, Mato Grosso do Sul State, Brazil.

PAULO LANDGREF FILHO (e-mail: paulograf@yahoo.com.br), **MAURÍCIO NEVES GODOI** (e-mail: mauricioecologia@hotmail.com), and **CAMILA AOKI** (e-mail: aokicamila@yahoo.com.br), Programa de Pós-Graduação em Ecologia e Conservação, Centro de Ciências Biológicas e da Saúde, Universidade Federal de Mato Grosso do Sul, 79070-900, Campo Grande, MS, Brazil.

***RHACOPHORUS GAUNI* (Short-nosed Tree Frog). HIGH ELEVATION RECORD.** *Rhacophorus gauni* is a small, slender anuran (to 38 mm SVL) recognized by its short rounded snout, upright pointed dermal spikes on the upper eyelids, noticeable white spots below the eyes, light brown dorsum with indistinct dark spots, and reddish orange inner thighs (Inger 2005. The Systematics and Zoogeography of the Amphibia of Borneo. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 402 pp.; Inger and Stuebing 2005. A Field Guide to the Frogs of Borneo. 2nd ed. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 201 pp.). *Rhacophorus gauni* is endemic to Borneo, Sabah and central Sarawak of Malaysia, Brunei Darussalam, and western and northeastern Kalimantan of Indonesia (Inger et al. 2004. *Rhacophorus gauni*. *In* IUCN 2010. IUCN Red List of Threatened Species. Version 2010.3. <www.iucnredlist.org>. Accessed 24 Sept 2010; Das 2007. A Pocket Guide: Amphibians and Reptiles of Brunei. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 200 pp.). The species lives in primary forests (Malkmus et al. 2002. Amphibians and Reptiles of Mount Kinabalu [North Borneo]. A.R.G. Gantner Verlag K.G. Ruggell. 424 pp.; Inger 2005, *op. cit.*). Due to dwindling primary forest, *R. gauni* is listed as Near Threatened in the 2010 IUCN Red List of Threatened Species (Inger et al. 2004, *op. cit.*). Previous publications reported the altitudinal range for the species to be from near sea level to 980 m (Inger and Stuebing 2005, *op. cit.*; Frost 2010. Amphibian Species of the World: an Online Reference. Version 5.4 [8 April 2010]. Electronic database accessible at http://research.amnh.org/vz/herpetology/amphibia. Amer. Mus. Nat. Hist., New York. Accessed 24 Sept 2010). Herein we report a new elevational limit for *R. gauni*.

On 1 Oct 2008, between 1900 and 2200 h, an adult *R. gauni* (29 mm SVL, 1.2 g) was collected at Sungai Lidan (5.9839°N 116.5261°E; 1215 m elev.), Bundu Tuhan, Ranau District, West Coast Division, Sabah, Bornean Malaysia. The individual was found perched on a 2.5 m high rattan leaf overhanging the clear and moderately flowing Sungai Lidan with a rocky bottom—a preferred habitat type for *R. gauni* (Malkmus et al. 2002, *op. cit.*; Inger 2005, *op. cit.*). Air temperature was 16°C; relative humidity was 86.5%. Sungai Lidan is one of the main streams in Bundu Tuhan with rattan, bamboo, and ginger on the banks. Other anurans, including *Ansonia hanitschi, A. longidigita, Leptolalax pictus, Meristogenys orphnocnemis, Staurois latopalmatus, S. tuberilinguis,* and *Rhacophorus rufipes* occur in this rocky stream habitat. This locality represents an extension of habitat for *R. gauni* from lowlands and hilly terrain to the submontane zone. The specimen (HEP00674) was deposited in BORNEENSIS, the Bornean reference collection of the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah.

We are grateful to Agnes James Lintanga for field assistance, Paulus Abas for field transportation and Haleluyah Retreat Centre for lodgings support. Sampling was conducted under permission granted by Jawatankuasa Pemegang Amanah Hutan Simpanan dan Tanah Perumahan Bumiputera Kg. Bundu Tuhan, Ranau, to KBH. We also thank the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah for support.

***SMILISCA BAUDINII* (Mexican Treefrog). PREDATION.** On 24 Aug 2010, 1600 h local time, at the Organization for Tropical Studies field station at Parque Nacional Palo Verde, Provincia Guanacaste, Costa Rica (10.34547°N, 85.33889°W), we observed a male *Crax rubra* (Great Curassow) seize an adult *Smilisca baudinii* with its beak during a predatory attack. The frog emitted its characteristic alarm call as the Great Curassow quickly walked away with it. It is presumed that the bird consumed the frog, although it is possible that the frog eventually escaped; in any event, it is assumed the intention of the bird was to eat the frog. Although up to 5% of their diet is composed of small vertebrates, this is the first known instance of a Great Curassow feeding upon an amphibian (Muoz and Kattan 2007. Ornithologica Neotropical 18:21–36), and to our knowledge the first reported instance of a bird feeding upon *S. baudinii* (Malone 2005. *In* M. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 489–491. Univ. California Press, Berkeley).

This observation was made under RESOLUCIÓN No 018-2009-ACAT (MINAET, Ministry of Environment, Energy, and Telecomunications) while conducting research funded by the NSF IRES grant to the Organization for Tropical Studies.

SEAN P. GRAHAM, Auburn University, Department of Biological Sciences, Auburn, Alabama 36849, USA (e-mail: grahasp@auburn.edu); **NATHAN D. BURKETT-CADENA**, Auburn University, Department of Entomology and Plant Pathology, Auburn, Alabama 36849, USA.

***SPEA HAMMONDII* (Western Spadefoot). PREDATION.** Invertebrates are a major predator of amphibians in many freshwater settings. Indeed, predatory pressure on eggs by dytiscid larvae is one reason suggested for the diversification of oviposition strategies in South American anurans (Magnusson and Hero 1991. Oecologia 86:310–318). Breeding adult amphibians have been documented as prey for dytiscid beetle larvae (Hinshaw and Sullivan 1990. J. Herpetol. 24:196–197), and dytiscid beetle larvae were found to be effective predators of *Rana sylvatica* larvae in a naturalistic predation experiment (Rubbo et al. 2006. J. Zool. 269:1–5). In the latter experiment, researchers found that *R. sylvatica* tadpoles recognized chemical cues and avoided areas inhabited by dytiscid beetle larvae, indicating a shared evolutionary relationship. In short-duration or ephemeral pools, amphibians face trade-offs between maximizing tadpole age and body mass, ostensibly by inhabiting pools with longer hydroperiods, and minimizing predation risk through earlier metamorphosis driven by pools with shorter hydroperiod

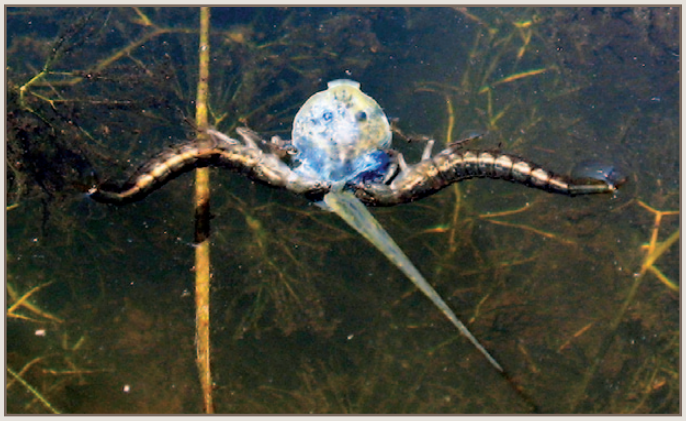

FIG. 1. Larval *Spea hammondii* succumbing to predation by two dytiscid beetle larvae.

(Morey 1996. *In* Witham et al. [eds.], Ecology, Conservation, and Management of Vernal Pool Ecosystems, pp. 86–91. Proceedings from a 1996 Conference. California Native Plant Society, Sacramento, California). Here, we document an isolated instance of predation on *Spea hammondii* by larval dytiscid beetles, which, although previously unreported in a vernal pool ecosystem, may be a common predator-prey relationship in intact vernal pool landscapes.

On 8 April 2010, at 1530 h, in an unincorporated area south of Rancho Murieta in northern California, we observed two large (± 60 mm) larval dytiscid beetles (*Dytiscus* sp.) preying upon a larval *S. hammondii* within the upper column of an ephemeral pool (Fig. 1). It appeared the tadpole was very recently killed, we assume by the beetle larvae, and at the start of our observation the tadpole still exhibited a righting response. Water clarity was very good, and no other dead tadpoles or other aquatic organisms were observed. The two beetle larvae had grasped the tadpole on either side of the body, basal to the tail. We watched for 9–10 min as the beetle larvae appeared to feed and wrestle the *Spea* larva into different positions. In the same pool within a slowly flowing ephemeral drainage were an additional 150–200 *Spea* tadpoles, all apparently healthy and mostly aggregated into shallow water with relatively thick submerged and emergent herbaceous vegetation (*Deschampsia danthanoides, Glyceria declinata, Ranunculus aquatilis, R. bonariensis, Trifolium variegatum*). Areas of deeper (ca. 60 cm) open water were present and water did not appear to be limiting, but tadpoles were not observed in these. Most tadpoles, including the prey item, were of large size (50–60 mm total length) and Gosner stages 26–34 (Gosner 1960. Herpetologica 16:183–190). At least two cohorts were apparent. One additional dytiscid larva of the same approximate size as the predators was observed swimming and floating 0.5 m from the presumed predation event within the water column. The ambient temperature at the time of observation was ca. 25°C, water temperature was 23.5°C.

Like many vernal pool organisms, *S. hammondii* have developed adaptations for dealing with short hydroperiod and severe water chemistry attributes (Burgess 1950. Copeia 1950:49–50; Morey, *op. cit.*). Along with the abiotic criteria, predation surely plays a large role in regulating population processes. However, to our knowledge, predation by aquatic invertebrates has not been reported for *Spea hammondii*.

ERIC W. STITT (e-mail: estitt@ecorpconsulting.com) and **PETER S. BALFOUR** (e-mail: pbalfour@ecorpconsulting.com), ECORP Consulting, Inc., 2525 Warren Drive, Rocklin, California 95677, USA.

SQUAMATA — LIZARDS

***BACHIA HETEROPA ALLENI* (Earless Worm Lizard). ESCAPE AND DIGGING BEHAVIORS.** From 3 to 22 June 2010 on Union Island, St. Vincent the Grenadines, we had 43 encounters with *Bachia heteropa alleni*. Lizards typically were under rocks surrounded by leaf litter. Escape behaviors entailed quick retreats into leaf litter or cracks and crevices in hard substrates, burrowing rapidly in loose soil, or using their disproportionately long tails to "tail-slap" the surface, launching themselves into the air. We recorded examples of the latter two behaviors with a high-speed Casio Exilim FX-1 camera (Casio Computer Co., Ltd., Tokyo).

While burrowing, the lizard employed a serpentine posture to provide traction while using its head as a wedge, which was jammed repeatedly into the soil and moved laterally to enlarge the opening (Fig. 1). Limbs were loosely suspended and not held tightly against the body, nor were they used for either traction or removing debris.

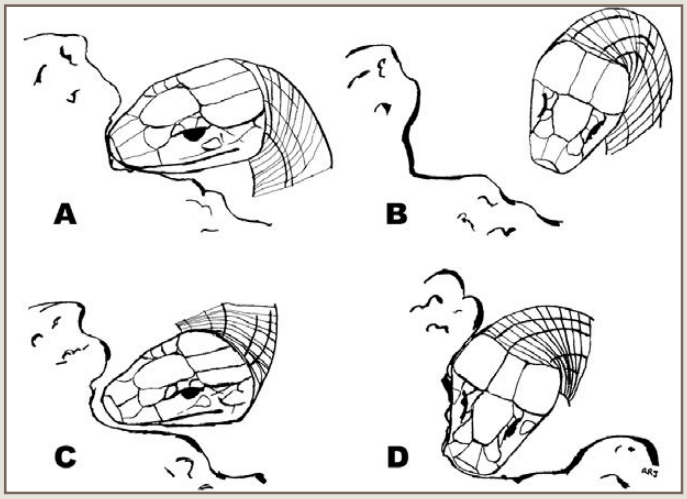

FIG. 1. Burrowing behavior of *Bachia heteropa alleni* (drawn from a high-speed video recording by RRJ). The head is wedged into the soil with traction provided by a serpentine posture primarily involving the tail (A), the head and body are retracted (B), the head is jammed repeatedly into the soil and moved laterally to enlarge the opening (C & D), with actions repeated until the body is covered.

Once initiated, the process was completed (body entirely underground) in 24 sec. The tail tip protruded when efforts ceased.

Undisturbed movement on the surface was serpentine, but lizards would quickly revert to "tail-slapping" when threatened. Tail-slapping consisted of forcefully depressing the entire tail, beginning at the base, against the substrate, in the process elevating the body and ultimately the tail into the air. In the recorded episode, the lizard sporadically threw itself into the air with limbs loosely suspended, often losing all contact with the substrate. It frequently landed on its side or back, quickly rotating back to an upright position before repeating the maneuver.

If captured, individuals would attempt to escape by rolling their bodies, like turning a screw or somewhat similar to an alligator "death roll." As in digging and tail-slapping, limbs were not used and were held loosely by the body.

Permits to conduct research on Union Island were issued by Mr. Brian Johnson, Director, Department of Forestry, St. Vincent and the Grenadines. Protocols were approved by the Avila University Animal Care and Use Committee. Fieldwork was funded by a grant from the National Science Foundation (USA) to Robert Powell (DBI-0851610).

***CARLIA AILANPALAI* (NCN). HERMAPHRODITISM.** *Carlia ailanpalai* occurs in Manus Province, Papua New Guinea and also on Guam, Mariana Islands, Yap and Korae (Zug 2004. Bishop Mus. Bull. Zool.5:1–83). In this note I report a hermaphroditic *C. ailanpalai* (SVL = 51 mm), collected June 1996 from Saipan Island,

FIG. 1. Hermaphroditic gonad of *Carlia ailanpalai*. A = seminiferous tubules; B = atretic follicle with enlarged granulosa cells; c = normal ovarian follicle. Bar represents 1000 µm.

Commonwealth of the Northern Mariana Islands, (15.215391°N, 145.722695°E, datum WGS84; elev. 0–10 m). It was deposited in the Bishop Museum (BPBM), Natural Sciences Department, Vertebrate Zoology, Honolulu, HI as BPBM 26936.

A lateral incision was made on the lower left side and the left gonad was removed for histological examination. It was embedded in paraffin and histological sections were cut at 5 µm and stained with Harris' hematoxylin followed by eosin counterstain. A voucher histology slide was deposited at BPBM.

In the testis portion (Fig. 1A) seminiferous tubules contained mainly primary spermatocytes and occasional secondary spermatocytes. In the female portion, two follicles were present, one of which was a degenerating atretic follicle (Fig. 1B) in which the granulosa cells had markedly enlarged and projected into the interior of the follicle. The other appeared normal (Fig. 1C) and was not undergoing yolk deposition. It was not possible to ascertain if either the female or male portion of the gonad would have produced mature gametes. Hermaphroditism is rare in lizards (Brown 2008. Biawak 2:87–88; Goldberg 1989. Copeia 1989:486–488). This is the first report of hermaphroditism in *C. ailanpalai*.

I thank Christine Thacker (Natural History Museum of Los Angeles County) for the photomicrograph and Pumehana Imada (BPBM) for facilitating my examination of *C. ailanpalai*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

***CNEMASPIS ASSAMENSIS* (Assamese Day Gecko). HABITAT.** *Cnemaspis assamensis* was described from Mayeng Reserve Forest within the Kamrup District of Assam. The species was recorded from within a subtropical evergreen forest on a tree trunk, 35–148 cm from the ground (Das and Sengupta 2000. J. S. Asian Nat. Hist. 5:17–23). The species was also recorded from a tree trunk in Garbhanga Reserve Forest, Kamrup District of Assam (Sengupta et al. 2000. J. Assam Sci. Soc. 41:372–378). Das and Ahmed 2007 (Zoos' Print J. 22:2720) reported the species from tropical semi-evergreen forest of Diffolu Camp, in the Ghorakhati Range of Kaziranga National Park. They observed the species on the trunk of a tree (*Ficus bengalensis*), 1 m above the ground and on a rock in the ground beside a small tree in Kukurakata Reserve Forest. In all the aforementioned records, the lizard was reported from within naturally forested areas. Here we report on the occurrence of this species from an anthropogenic habitat.

On 24 September 2009, we found six individual *C. assamensis* on the outer wall of a two-storied concrete building in the residential area of Kamakhya Temple (26.1642713°N, 91.7076637°E; 171 m elev.) during a herpetological investigation of Guwahati City, Kamrup District of Assam. Although commonly regarded as a diurnal gecko species, we encountered them at around 1930 h. Two of the individuals were captured and photographed. The lizards were found at a height of about 2.5 m from the ground and were observed coexisting on the wall with *Hemidactylus frenatus*.

JAYADITYA PURKAYASTHA (e-mail: jaya_ditya@rediffmail.com) and **MADHURIMA DAS** (e-mail: write.madhu@rediffmail.com), Herpetological Division, Help Earth, Guwahati-781007, India.

***COLEONYX BREVIS* (Texas Banded Gecko). INVERTEBRATE INTERACTIONS.** *Coleonyx brevis* is a secretive and nocturnal lizard that often spend a considerable amount of time in dark microhabitats including, but not limited to, underneath rocks, under other objects, and within crevices (Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., New York, New York. 533 pp.). Throughout the range of *C. brevis* these same microhabitats are often cohabited by various invertebrates including Striped Bark Scorpions (*Centruroides vittatus*) (pers. obs.). Herein we report three instances involving hatchling *Coleonyx brevis* running towards, and stopping next to, adult *Centruroides vittatus* after their cover had been lifted.

On 20 June 2002 at Amistad National Recreation Area, Pandale, Val Verde Co., Texas, USA (30.13026°N, 101.57430°W; 482 m elev.) between 2420–2425 h, a juvenile *Coleonyx brevis* was found beneath a wooden board. Upon the initial attempt to capture the specimen, the gecko raised its tail in the air and ran directly to an adult *Centruroides vittatus* whereupon it aligned its body parallel to that of the scorpion and became motionless. A pair of forceps was used to move the scorpion in an attempt to facilitate capturing the gecko. This elicited a flee response by the gecko and it ran towards and aligned itself alongside another resting *Centruroides vittatus* in the previously described manner. In both instances the gecko made physical contact with the scorpions and no reaction was elicited on their behalf.

During a second observation the next day on 21 June 2002 at 1215 h in Pandale, Texas (30.075982°N, 101.574196°W), a hatchling *Coleonyx brevis* was found beneath a flat rock. When a capture attempt was made the lizard ran and stopped between two resting *Centruroides vittatus*. While between the scorpions, the gecko assumed a submissive posture with the head lowered and body and tail pressed against the ground. A flight response was elicited after one of the scorpions was moved with a pair of forceps.

During a third observation on 1 August 2007 in close proximity of Minerales de Monclova (27.87646°N, 101.30571°W), Coahuila, Mexico at 1356 h, a hatchling *Coleonyx brevis* was discovered after lifting a rock. During an attempt to capture the specimen it ran towards and paused alongside a resting *Centruroides vittatus*. However, continued capture attempts caused the scorpion to leave the area and no additional observations pertaining to the gecko and scorpion were made.

To date we have not noticed any of the aforementioned behavior among adult *Coleonyx brevis*. Based upon our accounts it seems that

the geckos are benefiting from the presence of the scorpions without any consequence or cost for the scorpions. Although these behaviors by juvenile geckos are suggestive of commensalism, a quantitative analysis is required to better understand the significance of these observations.

CARL J. FRANKLIN, Amphibian and Reptile Diversity Research Center, University of Texas at Arlington. Box 19498, Arlington, Texas 76019, USA (e-mail: Franklin@uta.edu); **DAVID C. KILLPACK**, Illumination Studios, 1605 High Valley Lane, Cedar Hill, Texas 75104, USA.

***DIPOGLOSSUS LESSONAE* (Brazilian Galliwasp) DIET.** The anguid *Diploglossus lessonae* is a diurnal and active forager, widely distributed in northeastern Brazil (Atlantic Forest and Caatinga). It is a terrestrial and semi-fossorial species usually associated with leaf litter, fallen logs, and crevices in rocks.

Although described over a century ago, the ecology of this species is poorly known. Some data regarding its diet based on a population from Exu (Pernambuco State, Brazil) have been provided (Vitt 1985. Pap. Avul. Zool. 36:69–76; Vitt 1995. Occas. Pap. Oklahoma Mus. Nat. Hist. 1:1–29). However, the diet of *D. lessonae* remains poorly studied. According to these previous dietary studies, prey includes invertebrates of the orders Araneae, Coleoptera, Dermaptera, Hemiptera, Opiliones, Orthoptera, Scorpiones, and insect larvae (Vitt 1985, *op. cit.*; Vitt 1995, *op. cit.*). Herein, we expand the knowledge regarding the feeding ecology of *D. lessonae* through the first record of two new orders of invertebrates included in its diet.

We examined 10 individuals—four males and six females—deposited in the scientific collection Coleção de Herpetologia da Universidade Federal do Ceará (CHUFC). Lizards were dissected and diet was assessed by stomach content analysis. Prey items present in the stomachs were identified as the following arthropod orders: Araneae, Blattodea, Coleoptera (elytra and Elateriform larvae), Hymenoptera, Orthoptera, and Scorpiones. Therefore, this is the first record of the orders Hymenoptera and Blattodea included in the diet of *D. lessonae*.

We thank Laís Machado and Conrado Galdino for providing valuable suggestions on the manuscript.

***HEMIDACTYLUS FLAVIVIRIDIS* (House Gecko). BIFURCATION.** *Hemidactylus flaviviridis* is the most common gecko of the genus *Hemidactylus* occurring throughout the Indian sub-continent. It occupies a variety of habitats including tree trunks, rocks, and on walls of buildings (Daniel 1983. The Book of Indian Reptiles. Bombay Nat. Hist. Soc. Oxford University Press, Bombay. 141 pp.). On 30 March 2010 at 1942 h we observed an adult male *H. flaviviridis* with a bifurcated (or bifid) tail in a residential house in Palus, District, Sangli, Maharashtra, India (16.75°N, 73.70°E). The tail of the lizard was bifurcated in the posterior region. The right bifurcation of the tail was longer than the left. There are many reports of natural occurrences and experimental manipulation of bifid and trifid tails in lizards (Brindley 1894. J. Bombay Nat. Hist. Soc. 9:30–33; Das 1932. J. Bombay Nat. Hist. Soc. 35:657–662).

FIG. 1. Photograph depicting the adult male *Hemidactylus flaviviridis* with bifurcated tail (right) compared with a normal-tailed female (left).

***PHRYNOSOMA BLAINVILLII* (Coast Horned Lizard). COMMENSALISM.** The use of burrows as refugia by herpetofauna that have been constructed by other animals (mainly rodents) has been observed for a wide range of species. For some of these relationships, commensalism has been suggested, with the ectothermic amphibian or reptile species benefiting from the microhabitat created by the rodent. Examples, which may be locality and temporally dependent, include Oldfield Mouse (*Peromyscus polionotus*) burrow use by the Six-lined Racerunner (*Aspidoscelis sexlineatus*) (Pearson and Nelson 1952. Copeia 1952:188–189), Southeastern Pocket Gopher (*Geomys pinetis*) burrow use by the Mole Skink (*Plestiodon egregarius*) and Southeastern Crowned Snake (*Tantilla coronata*) (Funderburg and Lee 1968. J. Herpetol. 1:99–100), California Ground Squirrel (*Spermophilus beecheyi*) burrow use by the California Tiger Salamander (*Ambystoma californiense*) (Laredo et al. 1996. J. Herpetol. 30:282–285), and Gunnison's Prairie Dog (*Cynomys gunnisoni*) burrow use by the Lesser Earless Lizard (*Holbrookia maculata*) (Davis and Theimer 2003. Amer. Midl. Nat. 150:282–290).

The use of rodent burrows by horned lizards (*Phrynosoma* spp.) is well documented (Hagar and Brattstrom 1997. Southwest. Nat. 42:339–344; Milne and Milne 1950. Amer. Midl. Nat. 44:721–741; Tappe 1941. J. Mammal. 22:117–148; Wone and Beauchamp 2003. J. Herpetol. 37:679–686), but obligate dependency on such burrows for their survival is not. Here we report on the first observed commensal relationship between the Coast Horned Lizard (*Phrynosoma blainvillii*) and the California Kangaroo Rat (*Dipodomys californicus*).

Throughout its diminishing range in California, *P. blainvillii* occurs in an array of habitats including chaparral, coastal sage scrub, open coniferous forest, broadleaf woodland, pinyon-juniper woodland, Joshua Tree woodland, and grassland (Lemm 2006. Field Guide to Amphibians and Reptiles of the San Diego Region. Univ. California Press, Berkeley, 326 pp.; Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 533 pp.; pers. obs.). Shrubs and other low-growing woody vegetation are typically significant components within such

habitats, which horned lizards use to escape predation and for thermoregulation in the shade provided as the position of the sun shifts throughout the day (Heath 1965. Univ. California Misc. Publ. Zool. 64:97–129; Sherbrooke 2003. Introduction to Horned Lizards of North America. Univ. California Press, Berkeley, 178 pp.; Tanner and Krogh 1973. Herpetologica 29:327–342; pers. obs.).

In a grassland community in the northern Sierra Nevada at Table Mountain, Butte Co., California, shrubs do not exist on the open plateau where a population of *P. blainvillii* occurs. Other shade-providing woody vegetation (e.g., Blue Oak, *Quercus douglasii*, and Foothill Pine, *Pinus sabiniana*) are present only in localized areas on the plateau that are not inhabited by horned lizards. However, the open burrows of *Dipodomys californicus* are ubiquitous. *Phrynosoma blainvillii* occurs on expanses of exposed basalt bedrock on the open plateau, which lacks the loose soil characteristic of its habitats in other parts of California. A community of low-growing grasses and forbs occurs throughout the Table Mountain plateau between areas of exposed basalt, but the landscape is entirely devoid of shrubs, large rocks, or any other cover that would provide sufficient shade for the lizards. Small basaltic rocks lie flat on the ground, often embedded in Hansen's Spike-moss (*Selaginella hansenii*), and are not large enough to provide suitable cover. Burrows of *D. californicus* are typically found along the edges of the exposed basalt. The mounds created by Botta's Pocket Gopher (*Thomomys bottae*) activity are also present; however, the entrances to burrow chambers are inaccessible to retreating horned lizards as they are covered by soil. Burial into these exposed mounds during peak spring and summer temperatures is unlikely to bring sufficient protection from overheating due to lack of shade over the mound. Given this open habitat, we suggest that this population of *P. blainvillii* would likely not exist in the absence of *D. californicus*. This presumptive dependence on rodent burrows for shelter is supported by the following observations.

At 1045 h on 20 May 2007, a sub-adult male *P. blainvillii* was found emerging from a *Dipodomys* burrow, suggesting its likely use as an overnight refuge. Later the same day at 1300 h an adult (not sexed) *P. blainvillii* was observed sleeping in the mouth of a *Dipodomys* burrow, head facing outward. The lizard was just out of reach of sunlight in the shade of the burrow. On 18 May 2008, an adult female *P. blainvillii* was discovered at 1130 h just outside the entrance of a *Dipodomys* burrow and then retreated into it. At 1145 h that same day, a large adult male was observed sleeping inside a *Dipodomys* burrow, tail facing outward. As 37.8°C was the recorded high for this date, air and ground temperatures were very warm by this time (no temperature data available at time of observation). On 8 June 2008, a juvenile (not sexed) was observed at 1140 h with tail facing outward in the mouth of a *Dipodomys* burrow, again during warming temperatures (recorded high for this date was 32.2°C). On 24 May 2009 a juvenile female was observed in a *Dipodomys* burrow at 1129 h; air temperature was 23°C at the time the lizard was observed. Because this recorded temperature is relatively cool for activity at this locality (pers. obs.) and the observed temperature high for this date was 26.1°C, it is possible that this individual might have used the burrow for an overnight refuge and had not yet initiated activity for the day. On 29 May 2010 a juvenile female was observed in a *Dipodomys* burrow at 1410 h, with head facing outward, but entirely within the burrow. Ground temperature outside the mouth of the burrow was 53.05°C; temperature where the horned lizard was located within the burrow was 21.1°C. Other, active horned lizard individuals observed at this locality during optimal conditions for surface activity were also always found on relatively flat, exposed basalt bedrock with kangaroo rat burrows in the vicinity.

Because of the habitat characteristics of this unique community, other questions arise regarding the ecology of *P. blainvillii* and its relationships with these rodents: Does this population of *P. blainvilli* use the *D. californicus* burrows and/or the pocket gopher mounds for brumation sites or for oviposition sites? Was this commensal relationship between *P. blainvillii* and rodents such as *D. californicus* a more widespread phenomenon throughout historical grassland communities of the Central Valley and its adjacent foothills prior to the lizard's extirpation from much of the region due to extensive cultivation, urbanization, and introduction of invasive annuals (Germano et al. 2001. Wildl. Soc. Bull. 29:551–559; Leaché et al. 2009. PNAS 106:12418–12423)?

We thank W. Hodges and W. Sherbrooke for their helpful comments and M. Garcia, C. Martin, J. Nelson, M. Ocken, K. Paul, J. Silveira, and M. Skram for their time and enthusiasm.

KIRN** (e-mail: sakirn@csuchico.edu) Department of Biological Sciences, California State University at Chico, Chico, California 95929-0515, USA.

***PHRYNOSOMA MODESTUM* (Round-tailed Horned Lizard). PREDATION.** Predation on *Phrynosoma modestum* has been documented for lizards (*Gambelia wislizenii*, *Crotaphytus collaris*), birds (*Geococcyx californianus*, *Lanius ludovicianus*), and rodents (*Onychomys* spp.) (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. of New Mexico Press. Albuquerque. 431 pp.; Hodges 2009. *In* Jones and Lovich [eds.], Lizards of the American Southwest, pp.186–189. Rio Nuevo Publ., Tucson, Arizona; Sherbrooke 2003. Introduction to Horned Lizards of North America. Univ. of California Press, Berkeley. 177 pp.). Herein we report the first record of predation on *P. modestum* by the Pallid Bat (*Antrozous pallidus*).

On 11 October 2007 at 2230 h, a freshly killed female hatchling *P. modestum* (SVL 39 mm) was found under an *Antrozous pallidus* night roost, along with various arthropod remains, at the entrance to the bathroom facility on Indio Mountains Research Station (IMRS), located in the Trans-Pecos area of the Chihuahuan Desert, ca. 40 km SW of Van Horn, Hudspeth Co., Texas, USA (30.782778°N, 105.015278°W, WGS84; 1233 m elev.). The hatchling had been partially consumed, thereby missing its tail and the right hind limb. Nocturnal predation on *P. modestum* and other normally diurnal lizards by *A. pallidus* on IMRS (Lenhart et al. 2010. Southwest. Nat. 55:110–115) is not entirely surprising given their frequently observed movements at night during the warm months of the year (Degenhardt et al., *op. cit.*; pers. obs.). Unlike most bats on IMRS, *A. pallidus* gleans most of its food from the ground and low vegetation (Lenhart et al., *op. cit.*). The lizard is deposited in the Herpetology Collection, Laboratory for Environmental Biology, Centennial Museum, The University of Texas at El Paso (UTEP 20007).

VICENTE MATA-SILVA (e-mail: vmata@miners.utep.edu) and **JERRY D. JOHNSON** (e-mail: jjohnson@utep.edu), Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968, USA.

***PHRYNOSOMA ORBICULARE* (Mexican Plateau Horned Lizard). ENDOPARASITES.** *Phrynosoma orbiculare* is restricted to Mexico and occurs in the Sierra Madre Occidental of central western Chihuahua southward into Puebla and northward in the Sierra Madre Oriental to southern Nuevo León and Coahuila (Lemos Espinal

and Smith 2007. Amphibians and Reptiles of the State of Coahuila, México. Univ. Nac. Autón. México, México, D.F. 550 pp.). To our knowledge, there are no reports of helminths from this species. The purpose of this note is to establish the initial helminth list for *P. orbiculare*.

One female *P. orbiculare* (SVL = 66 mm) collected 29 April 1966 at Xochimilco Districto Federal (19.5°N, 99.20166°W, datum WGS84; elev. 2255 m) was borrowed from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA. The body cavity (LACM 36699) was opened and the digestive tract removed. Contents were examined under a dissecting microscope. In the large intestine were 185 nematodes. They were cleared in a drop of glycerol, placed on a microscope slide, cover slipped, studied under a compound microscope and identified as *Cyrtosomum penneri*. Voucher helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as USNPC (103548).

Cyrtosomum penneri is a common nematode in horned lizards and has been reported in *P. asio*, *P. mcallii* (Gambino and Heyneman 1960. Amer. Midl. Nat. 63:365–382), *P. blainvillii* (as *P. coronatum*) (Telford 1970. Amer. Midl. Nat. 83:516–564), *P. cornutum*, *P. hernandesi* (as *P. douglassi*), *P. platyrhinos*, *P. solare* (Goldberg et al. 1993. J. Helminthol. Soc. Washington 60:234–238) as well as some 26 additional lizard species (see McAllister and Bursey 2007. Comp. Parasitol. 74:179–184). Three species of *Cyrtosomum* have been reported from Mexican hosts: *C. longicaudatum*, *C. penneri*, and *C. scelopori* (Gambino and Heyneman 1960, *op. cit.*; Caballero Deloya 1971. Ann. Inst. Biol. Univ. Nac. Autón. México 42:29–34). These species are separated based on the morphology of spicules and number of caudal papillae: *C. longicaudatum*, unequal spicules, 16 papillae; *C. penneri*, unequal spicules, 12 papillae; *C. scelopori*, equal spicules, 12 papillae (Bursey and Flanagan 2002. J. Parasitol. 88:320–324). Our specimens fit the description of *C. penneri*. *Cyrtosomum* belongs to the Atractidae; transmission between hosts is not understood (Anderson 2000. Nematode Parasites of Vertebrates, Their Development and Transmission. CABI Publ. Oxfordshire, U.K. 650 pp.), although Petter (1966. Mem. Mus. Nat. d'Hist. Natur. 39:1–252) speculated that infection in tortoises might occur during copulation. *Phrynsoma orbiculare* represents a new host record for *C. penneri*.

We thank Christine Thacker (LACM) for permission to examine *P. orbiculare* and Daniel Covarrubias (Whittier College) for assistance with dissection.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY**, Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

SCELOPORUS MUCRONATUS **(Cleft Lizard). SAUROPHAGY.** Studies regarding the feeding habits of *Sceloporus mucronatus* have documented an omnivorous diet in which the staple prey are insects (Méndez-de la Cruz et al. 1992. Southwest. Nat. 37:349–355; Vega-López and Alvarez 1992. Acta Zool. Mex. 51:1–128). Vega-López and Alvarez (1992, *op. cit.*) mentioned the presence of scales in the stomachs they analyzed, however, the identity of the species to which these belonged was not provided. Here we report a case of predation by *S. mucronatus* on a phrynosomatid lizard of the same genus.

On March 2010, we captured five specimens of *S. mucronatus* (one of which was found dead; deposited in the herpetological collection of the Benemérita Universidad Autónoma de Puebla as EBUAP 2115), in an oak forest (19.033°N, 98.115°W; 2240 m elev.) from Parque Estatal Flor del Bosque, located in the municipality of Amozoc, state of Puebla, México. To examine stomach contents, live specimens were stomach-flushed (Legler and Sullivan 1979. Herpetologica 35:107–110) and subsequently released. The dead specimen was dissected. Analysis of stomach contents revealed the presence of a partly digested neonate *S. grammicus* (ca. 25 mm SVL), ingested by an adult male *S. mucronatus* (74 mm SVL). Other contents observed were plant remains in four of the five specimens examined, and arthropods of the following orders: Araneae, Coleoptera, Diptera, Hemiptera, Hymenoptera (ants and others), and Lepidoptera (larvae). These observations confirm that at least one species of lizard is part of the diet of *S. mucronatus*, in addition to arthropods of several orders and plant material.

RICARDO LURÍA MANZANO, Laboratorio de Herpetología, Escuela de Biología, Benemérita Universidad Autónoma de Puebla, C.P. 72570, Puebla, México (e-mail: doumbek@hotmail.com); **EDUARDO Y. MELGAREJO VÉLEZ**, Secretaría del Medio Ambiente y Recursos Naturales "Parque Estatal Flor del Bosque," C.P. 72370, Puebla, México.

TIMON LEPIDUS **(Ocellated Lizard). PREDATION.** *Timon lepidus* is a widely distributed species in southern Europe (Gasc et al. 1997. Atlas of Amphibians and Reptiles in Europe. Collection Patrimoines Naturels, 29. SPN-IEGB-MNHN, Paris. 496 pp.), being the commonest large lizard in the Iberian Peninsula (Pérez-Mellado 1997. *In* A. Salvador [ed.], Reptiles, Fauna Ibérica Vol. 10, pp. 198–207. MNCN-CSIC, Madrid; Pleguezuelos et al. 2002. Atlas y Libro Rojo de los Anfibios y Reptiles de España. DGB-AHE. Madrid. 587 pp.). It forms the bulk, in terms of biomass, of the lacertid communities in Mediterranean environments (Pérez-Mellado 1997, *op. cit.*). Such a life history trait has driven its keystone position in the trophic webs of various habitats, where it forms an important part of the diet of a large number of predators (Martín and López 1996. Copeia 1996:722–726; Pérez-Mellado 1997, *op. cit.*).

Although this species is commonly consumed by terrestrial predators, its occurrence in the diet of freshwater-associated predators is anecdotal (Ruiz-Olmo 1995. *In* Llorente et al [eds.], Scientia Herpetologica, pp. 259–264. SHE-AHE. Barcelona; Clavero et al. 2005. Herpetol. J. 15:125–131.). In fact, there are no data on predation upon *T. lepidus*, despite its relative high abundance (Pérez-Mellado 1997, *op. cit.*).

We examined the feces (spraints) of a freshwater predator, the Eurasian Otter (*Lutra lutra*), for evidence of Ocellated Lizard remains. Spraints were stored and analyzed following standard procedures (Conroy et al. 1993. A Guide to the Identification of Prey Remains in Otter Spraints. Occas. Publ. Mammal Soc. 16, London. 52 pp.). The scat sample analyzed comes from the winters of 2007–2008 (21 spraints) and 2008–2009 (32 spraints). In one out of 53 spraints we found the skeletal remains of an adult *T. lepidus* (identified using the key of Barahona and Barbadillo 1997. Rev. Esp. Herpetol. 11:47–62). Expressed in percent biomass in the diet of the otter (applying the correction factors by Jedrzejewska and Jedrzejewski 1998. Predation in Vertebrate Communities. The Bialowieza Primeval Forest as a Case Study. Ecological Studies 135. Springer-Verlag, Heidelberg. 450 pp.), *T. lepidus* comprised 0.85%, a very low proportion.

This observation, although interesting because otters are almost entirely aquatic predators (Jedrzejewska et al. 2001. Ecography 24:165–180), most likely reflects an opportunistic feeding event because *T. lepidus* rest under rocks at night while otters are foraging during this time period (Pérez-Mellado 1997, *op. cit.*).

***XANTUSIA GILBERTI* (Gilbert's Night Lizard). REPRODUCTION.** *Xantusia gilberti* is a Baja peninsular endemic restricted to the oak and pine-oak woodlands of the upper elevations of Sierra la Laguna, Baja California Sur, México, where it is common above 1200 m (Alvarez et al. 1988. *In* L. Arriaga and A. Ortega [eds.], La Sierra de la Laguna de Baja California Sur, pp. 167–184. Centro de Investigaciones Biológicas de Baja California Sur A.C., La Paz). Anecdotal observations on microhabitat use of this species have been reported (Grismer 2002. Amphibians and Reptiles of Baja California Including its Pacific Islands and the Islands in the Sea of Cortez. Univ. California Press, Berkeley, California. 399 pp.), but virtually nothing is known of its reproductive habits. Here we report an observation that contributes to the timing of reproduction in this species.

On 26 August 2010, we captured an adult female (40 mm SVL, 47 mm tail, 1.5 g) *X. gilberti* beneath a pine tree log in pine-oak woodland, ca. 1 km NW of the Segundo Valle in the uplands of the Sierra la Laguna, Baja California Sur, México (23.5575°N, 109.9844°W; NAD 27; elev. 1745 m). Less than 10 cm from the female we observed two neonates (20 and 22 mm SVL; 15 and 20 mm tail; 0.3 and 0.5 g). We assume that these newborns were produced by the adult female found with them. Therefore, this is also an observation of young staying near the parent after birth. Based on the size of the young, we estimate that the birth happened during the first part of August.

Patricia Galina verified the species identification. One of the young lizards was deposited in the herpetological collection of the Centro de Investigaciones Biológicas del Noroeste (CIBNOR), La Paz, Baja California Sur, México (CIBNOR 1308).

VÍCTOR H. LUJA (e-mail: lujastro@yahoo.com), and **JAVIER BRUNO GRANADOS**, Centro de Investigaciones Biológicas del Noroeste (CIBNOR), Mar Bermejo #195 Colonia Playa Palo de Santa Rita, La Paz, Baja California Sur, 23090, México.

SQUAMATA — SNAKES

***BOA CONSTRICTOR* (Boa Constrictor). DIET.** *Boa constrictor* is a large tropical non-venomous snake that ranges from Mexico to northern Argentina and inhabits a variety of habitats including wet tropical forests, deserts, open savannahs, and cultivated fields. Prey include a wide variety of mammals, birds, and lizards (Reed and Rodda 2009. U.S. Geological Survey Open-File Report 2009–1202. 302 pp.). Here we describe a *B. constrictor* preying upon a domestic animal.

FIG. 1. Adult *Boa constrictor* consuming an adult Domestic Cat (*Felis silvestris catus*) in Nova Guarapari, Guarapari, Espirito Santo, Brazil.

On 29 August of 2005, at ca. 1400 h, an adult *B. constrictor* (total length > 1.5 m) was observed in the process of constricting a Domestic Cat (*Felis silvestris catus*) in Nova Guarapari, Guarapari City, Espirito Santo State, Brazil (20.7227778°S, 40.5383333°W; datum WGS84), within the yard of a local home (Fig. 1). The snake continued to consume the prey headfirst and soon attracted a crowd of several people. After the snake finished consuming its prey, it was removed from the site and released elsewhere.

Anthropogenic alteration or destruction of natural environments (e.g., deforestation and urbanization) can alter predator-prey relationships (Leme 1985. Boletim da Fundação Brasileira de Conservação da Natureza 20:57–67), force species into novel habitats, and result in the introduction of non-native taxa (Flinte et al. 2006. Rev. Bras. Entomol. 50:512–523; Schineider and Teixeira 2001. Iheringia, Sér. Zool. 91). This observation represents an additional record in the escalating list of conflicts between native and domestic wildlife (Bellati and Thungen 1990. *In* L. R. Davis and R. E. Marsh [eds.], Proceedings of the 14th Vertebrate Pest Conference, pp. 262–268. University of California, Davis). Importantly, *B. constrictor* may be one of the few native snakes capable of preying upon domestic or feral *F. s. catus*, which are widely recognized for their devastating impacts on populations of small native vertebrates (Burbidge and McKenzie 1989. Biol. Coserv. 50:143–198).

MIKAEL MANSUR MARTINELLI (e-mail: mansurmartinelli@yahoo.com.br), **THAIS DE ASSIS VOLPI**, Setor de Zoologia, Museu de Biologia Prof. "Mello Leitão," Avenida José Ruschi, 4, Santa Teresa, Espírito Santo, 29650-000, Brazil; and **ALZIR VAILLANT DE MATOS**,VIVERDE M.E., Rod. do Sol KM 05, S/N, Nova Guarapari, Guarapari, Espirito Santo, 29206305, Brazil.

***BOTHROPS JARARACUSSU* (Jararacussu). DIET.** *Bothrops jararacussu* is a venomous pitviper (to 2 m total length) with a diet that includes mammals, birds, amphibians, and insects (Freitas 2003. Serpentes Brasileiras. Bahia, Brazil. 160 pp.; Marques 2001. Serpentes da Mata Atlântica: Guia Ilustrado Para a Serra do Mar. 184 pp.). On 1 January 1998, an adult *B. jarracussu* (female; SVL = 1168 mm; tail length = 121 mm) was killed by a rural worker in Rio Nove, Santa Maria de Jetibá, Brazil (20.002087°N, 40.719045°E; datum WGS84). Upon dissection, we discovered three rodents, *Nectomys squamipes* (one adult and two juveniles), that had been swallowed head first. The lack of digestive activity indicates that the prey items had been swallowed recently and the presence of the adult female and two young rodents suggests that the snake may have raided the rodents' nest. The snake was deposited in the herpetological collection of Museu de Biologia Prof Mello Leitão (MBML 515), Santa Teresa, State of Espirito Santo, Brazil.

MIKAEL MANSUR MARTINELLI (e-mail: mansurmartinelli@yahoo.com.br), and **THAÍS DE ASSIS VOLPI**, Setor de Zoologia, Museu de Biologia Prof. "Mello Leitão," Avenida José Ruschi, 4, CEP 29650-000, Santa Teresa, Espírito Santo, Brazil.

***COLUBER CONSTRICTOR PRIAPUS* (Southern Black Racer). SCAVENGING AND DIET.** *Coluber constrictor* is an opportunistic predator that feeds on a wide variety of prey items including rodents, lizards, birds, amphibians, insects, snakes, and even small turtles (Ernst and Ernst 2002. Snakes of the United States and Canada. Smithsonian Institution Press, Washington D.C. 661 pp.). Here we describe two incidences of *C. constrictor* scavenging on road-killed *Opheodrys aestivus* (Rough Greensnakes).

On 19 June 2009, on Bald Head Island, Brunswick Co., North Carolina, USA, we observed an adult *C. constrictor* traversing the yard of our residence. The animal paused when it encountered the desiccated

remains of an *O. aestivus* that had been collected for measurement. After several tongue flicks the prey item was lifted, carried off, and consumed. During a snake road survey on 22 August 2009 we observed another adult *C. constrictor* carrying the remains of a freshly hit *O. aestivus* off the road. To our knowledge these records represent the first observations of scavenging by *C. constrictor* (Devault and Krochmal 2002. Herpetologica 58:429–436; Ernst and Ernst, *op. cit.*). Carrion foraging by snakes may be more prevalent than has traditionally been accepted (reviewed in Devault and Krochmal, *op. cit.*).

BRETT A. DEGREGORIO, Bald Head Island Conservancy, PO Box 3109, Bald Head Island, North Carolina 28461, USA (e-mail: Baretta66@hotmail.com); **ERIC J. NORDBERG**, Pennsylvania State University, State College, Pennsylvania 16802, USA (e-mail: Ejn5018@psu.edu).

***COLUBER* (= *MASTICOPHIS*) *FULIGINOSUS* (Baja California Coachwhip). DIET.** *Coluber fuliginosus* preys on a variety of species but most commonly feeds on lizards, small snakes, birds, and small mammals (Grismer 2002. Amphibians and Reptiles of Baja California including its Pacific Islands and the Islands in the Sea of Cortez. Univ. California Press, Berkeley, California. 399 pp.). Specifically, the following prey have been reported for *C. fuliginosus* from the Baja California Peninsula or its associated islands: *Sceloporus grandaevus, Dipsosaurus dorsalis, Aspidoscelis hyperythra, Sonora semiannulata,* and *Aspidoscelis tigris rubida* (Cliff 1954. Trans. San Diego Soc. Nat. Hist. 12:67–98; Grismer, *op. cit.*; Rodriguez-Robles and Galina-Tessaro 2005. Herpetol. Rev. 36:195). Here we report an attempted predation event, representing new diet item for *C. fuliginosus*. At 1200 h on 31 August 2007 near the Sierra del Mechudo, municipality of La Paz, Baja California Sur, México (24.8716667°N, 111.2527778°W; datum WGS84; elev. 156 m) in a rocky dry arroyo, we saw a *C. fuliginosus* that was biting the neck of a *Crotalus enyo* (Baja California Rattlesnake; Fig. 1). After about four minutes, the *C. fuliginosus* noticed our presence and moved away, leaving the potential prey dead and with bite marks on the tail, at midbody, and on the neck. We believe that the coachwhip was attempting to feed on the rattlesnake. Although this represents the first report of *C. enyo* in the diet of *C. fuliginosus,* the record is not unexpected; the closely related *Coluber flagellum* is known to feed on a variety of snakes species, including several species of rattlesnakes (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington DC. 668 pp.).

We thank Uri Omar García-Vázquez for comments and corrections to the manuscript.

ELÍ GARCÍA-PADILLA (e-mail: eligarcia_18©hotmail.com), **ISRAEL GUERRERO-CÁRDENAS** and **SERGIO ÁLVAREZ-CÁRDENAS**, Centro de Investigaciones Biológicas del Noroeste, Mar Bermejo 195, Colonia Palo de Santa Rita, La Paz, Baja California Sur 23090, México.

***CROTALUS HORRIDUS* (Timber Rattlesnake). NEONATE GROWTH.** Little information has been published regarding the ecology of neonate *Crotalus horridus*. Gibbons (1972. Copeia 1972:222–226) used size class data to examine the growth rate of juvenile *C. horridus* in spring and early summer over a three-year period. However, neonate growth has not been measured during the period between dispersal from parturition sites and the critical months leading up to hibernation.

We found an adult female *C. horridus* (SVL = 1126 mm) with a litter of 23 neonates (11 male, 12 female) in a shallow depression beneath a large log on 6 August 2009 in Baker Co., Georgia, USA. Snakes were held until their initial shed (5 days), after which they were measured and marked with either scale brands or passive integrated transponders (PIT tags). We attached 0.68 g radio transmitters to the tails of 15 neonates using Superglue® gel and released them at the natal site on 11 August 2009. We were able to relocate a portion of the telemetered snakes at regular intervals to collect growth data. Initial SVL of males ranged from 292.0–327.0 mm (mean = 314.1, N = 11) and masses ranged from 23.0–29.0 g (mean = 26.1, N = 11). SVL of females ranged from 302.5–330.0 mm (mean = 325.0, N = 12), and masses ranged from 21.0–28.0 g (mean = 28.0, N = 12).

Seven snakes were recaptured and measured 14 days after initial capture (Table 1). Neonates grew an average of 18.0 mm in SVL and lost 0.6 g in mass. The four snakes that were recaptured 41 days after initial capture had grown an average of 49.9 mm in SVL and gained 8.0 g. Morphological measurements were collected for one snake captured 74 days after initial capture; this individual grew 78.5 mm in SVL and gained 28.0 g.

TABLE 1. Growth data for juvenile *Crotalus horridus* in Baker Co., Georgia, USA. Data presented reflect the change in snout–vent length and mass from the date of the initial shed up to 74 d for one individual.

Snake ID	Sex	SVL (mm)			Mass (g)		
		14 d	41 d	74 d	14 d	41 d	74 d

CROTALUS TORTUGENSIS (Tortuga Island Rattlesnake). **DIET.** At 1035 h on 22 September 2009, an adult female *Crotalus tortugensis* (SVL = 656 mm; tail length = 40 mm) was detected on Tortuga

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. *Crotalus tortugensis* feeding on an adult male *Sceloporus orcutti*.

Island, Gulf of California, México (27.4333°N, 111.8667°W, datum WGS 84), as it rattled under rocks in a lava flow. When we located the snake we found it accompanied by a recently killed adult male *Sceloporus orcutti* (Granite Spiny Lizard; total length ca. 150 mm, Fig. 1). The snake proceeded to ingest the lizard over the next 25 min. Reports of the diet of this endemic rattlesnake mention only deer mice (*Peromyscus*) found in the stomachs of many specimens examined (Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. Univ. California Press, Berkeley. 1533 pp.; Van Denburgh 1922. The Reptiles of Western North America. Proc. California Acad. Sci., Vols. 1–2:1–1028). This observation represents a new diet record for *C. tortugensis*.

ELÍ GARCÍA-PADILLA (e-mail: eligarcia_18@hotmail.com), **GUSTAVO ARNAUD** (e-mail: garnaud04@cibnor.mx), **OSCAR CRUZ**, and **MARIA LUISA GRACIA**, Centro de Investigaciones Biológicas del Noroeste, Mar Bermejo 195, Colonia Palo de Santa Rita, La Paz, Baja California Sur, 23090 México.

***CROTALUS VIRIDIS* (Prairie Rattlesnake). DIET.** Adult *Crotalus viridis* are generalist predators known to feed on a variety of vertebrates, including a wide range of mammals and many ground-nesting birds, whereas juveniles feed primarily on small lizards (*Sceloporus* and *Holbrookia*; Werler and Dixon 2000. Texas Snakes. Univ. Texas Press, Austin. 437 pp.). Hamilton (1950. Herpetologica 6:34) noted the remains of several *Phrynosoma* sp. (surmised to be *P. douglasii* based on geographic proximity) in adult *C. viridis* specimens collected in the Black Hills of South Dakota, USA. This had been the only report of *C. viridis* preying upon lizards of the genus *Phrynosoma*; the following report adds *P. cornutum* to the diet of *C. viridis*.

On the morning of 4 June 2009, a live female *C. viridis* (TNHC 76278; SVL = 574 mm; tail length = 32 mm; 121.1 g) was collected by Albert Miller and Glen Nix roughly 5 km W of Valentine, Jeff Davis Co., Texas, USA (30.5607°N, 104.5928°W, datum WGS 84). Upon preserving the snake that afternoon, we found a recently ingested adult male *P. cornutum* (TNHC 76279; SVL = 102 mm; tail length = 45 mm; 32.6 g; swallowed headfirst) in the stomach of the snake.

We thank the Miller family for their support and assistance.

DREW R. DAVIS (e-mail: drewrdavis@gmail.com) and **TRAVIS J. LADUC** (e-mail: travieso@mail.utexas.edu), Texas Natural Science Center, The University of Texas at Austin, 10100 North Burnet Road, PRC 176/R4000, Austin, Texas 78758, USA.

***EUNECTES MURINUS* (Green Anaconda). DIET.** *Eunectes murinus* is an aquatic, nocturnal, and euryphagic snake species, feeding on several vertebrate types (fishes, frogs, turtles, lizards, snakes, caimans, birds, and mammals; Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:78–150; Strimple 1993. Herpetol. Nat. Hist. 1:25–35). Here we report the predation of an adult Tegu Lizard, *Tupinambis duseni*, by *E. murinus*.

On 17 September 2007, at 1125 h, at the edge of a stream in the area at Small Hydroelectric Power Plant - PCH Foz do Cedro, municipality of Lucas do Rio Verde (14.2083°S, 56.7766°W, datum: SAD 69), Mato Grosso State, Brazil, we observed a large adult *E. murinus* (total length > 2500 mm) in the process of constricting a *T. duseni*. When disturbed by our presence the snake dove into the water, allowing the lizard to escape.

***IMANTODES CENCHOA* (Blunt-headed Treesnake). DIET.** Various species are reported in the diet of *Imantodes cenchoa* from Manaus, Brazil; these include *Eleutherodactylus fenestratus*, *Anolis punctatus*, and *A. fuscoauratus* (Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:110–111). *Imantodes cenchoa* from the region of Los Tuxtlas, Veracruz, México feeds mainly on lizards of the genus *Anolis* (Higareda et al. 2007. Serpientes de la Región de los Tuxtlas, Veracruz, México. Guía de Identificación Ilustrada. Instituto de Biología, Universidad Nacional Autónoma de México, México D.F. 88 pp.). Here we report a new diet record for *I. cenchoa*.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. *Imantodes cenchoa* feeding on a specimen of *Anolis petersii*. Photo by Elí García-Padilla.

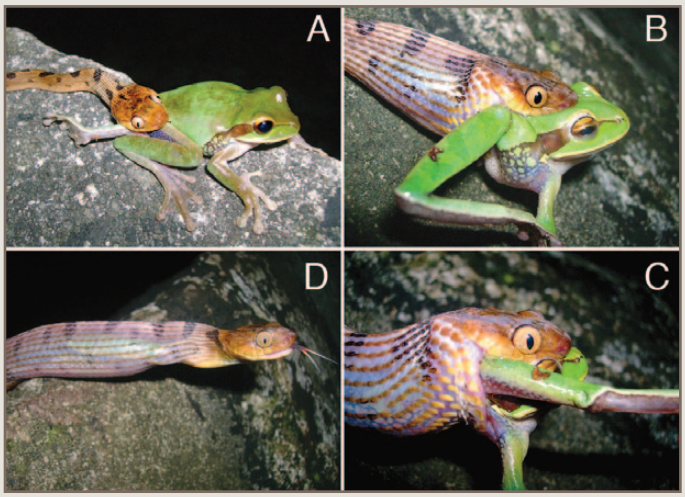
At 0030 on 21 July 2008, during a field expedition to the Los Tuxtlas region, Rancho los Ramos, municipality of San Andrés Tuxtla, Veracruz, Mexico (18.5861°N, 95.1172°W, datum: WGS84; elev. 431 m.) we found an adult *I. cenchoa* feeding on an *Anolis petersii* (Peters' Anole; Fig. 1). After we photographed the snake, it finished swallowing the lizard and moved away.

We thank Mariana Moreno Casper and Uri Omar García-Vázquez for comments and corrections on the manuscript.

ELÍ GARCÍA-PADILLA, Centro de Investigaciones Biológicas del Noroeste, Mar Bermejo 195, Colonia Palo de Santa Rita, La Paz, Baja California Sur, 23090 México (e-mail: eligarcia_18©hotmail.com); **HECTOR LUNA-ALCÁNTARA**, Instituto de Biología, Universidad Nacional Autónoma de México.

***IMANTODES CENCHOA* (Blunt-headed Treesnake). DIET.** *Imantodes cenchoa* is a common Neotropical arboreal snake that ranges from southern Mexico to Argentina. It is recognized for its long slender body and extremely thin neck. Solorzano (2004. Snakes of Costa Rica. Instituto Nacional de Biodiversidad, Santo Domingo de Heredia, Costa Rica. 791 pp.) states that small lizards (e.g., *Norops* and *Dactyloa*) and small frogs are common prey items. Additionally, Henderson and Nickerson (1976. J. Herpetol. 10:205–210) and Landry et al. (1966. J. Ohio Herpetol. Soc. 5:93–101) suggested that *I. cenchoa* may feed on the eggs of lizards but did not provide confirmation of this phenomenon. Here we report two instances of lizard egg predation by *I. cenchoa*.

On 13 November 2006 at 1901 h, in Parque Nacional G. D. Omar Torrijos Herrera, Coclé Province, Panamá, we found a juvenile *I. cenchoa* (SVL = 326 mm, total length = 466 mm, 3.3 g) that contained a small frog of the genus *Craugaster* (0.2 g) and a lizard egg (Polycrotidae; 0.4 g). The prey items totaled 18.2% of the snake's body mass. The prey items and snake were photographed (UTADC 6524–25) and the snake was released. On 8 March 2007 at 2236 h, in Parque Nacional G. D. Omar Torrijos Herrera, we found a female *I. cenchoa* (SVL = 986 mm, total length = 1439 mm, 56.4 g). This snake contained a *Dactyloa frenata* (19.1 g) and a large anole egg (1.3 g). The prey items totaled 36.2% of the snake's body mass. This snake was weak, but crawling along a branch next to the stream. It died soon after capture and when cut open to identify the prey item, the stomach was found to be perforated, presumably by a claw of the *D. frenata*. Photographs of the specimens were deposited at the Amphibian and Reptile Diversity Research Center, University of Texas at Arlington (UTADC 6526–27).



Sources to date have not confirmed the consumption of lizard eggs by *I. cenchoa*. The second snake reported here also contained a lizard in the gut, but the lizard was fully intact, implying that the egg was ingested on a separate occasion. The first snake did not contain any other lizard parts in the stomach, but contained an intact lizard egg. These records suggest that *I. cenchoa* does in fact feed on lizard eggs independent from consumption of lizards.

We thank J. A. Santana, Parque Nacional G. D. Omar Torrijos Herrera, the Smithsonian Tropical Research Institute, Autoridad Nacional del Ambiente (permit numbers SE/A-44-06), National Science Foundation (IBN-0429223, IBN-0429223, IOB-0519458), and researchers of the TADS Project for assistance, permission, and/or funding. We thank R. C. Jadin, J. W. Streicher, and J. A. Campbell for depositing the digital images at UTA.

***LEPTODEIRA SEPTENTRIONALIS POLYSTICTA* (Central American Cat-eyed Snake). DIET.** *Leptodeira septentrionalis polysticta* is a nocturnal colubrid that inhabits lowlands up to elevations slightly in excess of 2000 m from Nayarit and southern Veracruz, México, southward to central Costa Rica (Duellman 1958. Bull. Amer. Mus. Nat. Hist. 114:72). This species is known to feed on a wide variety of frogs (adults and eggs), lizards, and small mammals (Cabrera-Guzman et al. 2009. Herpetol. Rev. 40:99; Dehling 2009. Herpetol. Rev. 40:356; Duellman, *op. cit.*).

On 8 July 2008, at 2345 h, we encountered a breeding congregation of several adult *Smilisca cyanosticta* at the edge of an artificial reservoir (3 m × 1 m × 1 m) used for watering cattle along a dirt road near La Perla at Los Tuxtlas, Veracruz, México (18.5634°N, 95.1271°W, datum WGS84; elev. 600 m). We also observed two adult *L. s. polysticta*, one of which was in the process of feeding on a female *S. cyanosticta* (Fig. 1A–D). The snake held the hind leg of the frog and chewed it until the rear fangs were engaged. After three minutes, the frog's movement stopped and the snake swallowed it, starting at the posterior body portion, over the next ten minutes. Another predation event involving these species was observed several days later at the same location. This is the first record of *S. cyanosticta* in the diet of *L. septentrionalis*.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

***NERODIA FASCIATA FASCIATA* (Banded Watersnake). INTERWETLAND MOVEMENT.** Although many animals regularly display seasonal migrations or periodic long-distance dispersal, few instances of long-distance movements by snakes have been

reported (Browne and Bowers 2004. Landscape Ecol. 19:1–20; Roe and Georges 2007. Biol. Conserv. 135:67–76). Notable exceptions to this generalization are Australian Water Pythons (*Liasis fuscus*), which undertake up to 12 km seasonal migrations between floodplain and high-ground habitats (Madsen and Shine 1996. Ecology 77:149–156) and long-distance "wandering" of snakes displaced by humans (e.g., Plummer and Mills 2000. J. Herpetol. 34:565–575; Reinert and Rupert Jr. 1999. J. Herpetol. 33:45–61). *Nerodia fasciata* is a mid-sized natricine snake that is ubiquitous in the southeastern USA, occurring in virtually all aquatic habitats (Gibbons and Dorcas 2004. North American Watersnakes: a Natural History. Univ. Oklahoma Press, Norman. 438 pp.). Although this species is often abundant in isolated wetlands, these habitats may become unsuitable for aquatic snakes when severe droughts render them dry, sometimes for years at a time (Willson et al. 2006. Wetlands 26:1071–1078). Large numbers of *N. fasciata* captured leaving wetlands at the onset of droughts (Seigel et al. 1995. Herpetologica 51:424–434) have suggested that these snakes may emigrate overland to more permanent wetlands to escape drought conditions, but how far snakes travel and whether or not they successfully reach other aquatic habitats has not been confirmed. Here we report two *N. fasciata* that successfully moved long distances (> 3 km) between wetlands in response to drought.

Between February 2003 and June 2007, two of us (JDW and CTW) captured and marked over 900 individual *N. fasciata* at Ellenton Bay, a large Carolina bay wetland located on the Department of Energy's Savannah River Site in Aiken Co., South Carolina, USA. Ellenton Bay dried partially in the summer of 2006 and fully in June 2007. In 2007, one of us (TML) captured two marked *N. fasciata* in trashcan traps (Luhring and Jennison 2008. J. Fresh. Ecol. 23:445–450) at Dry Bay, a Carolina bay with a longer hydroperiod, located approximately 3.1 km N of Ellenton Bay. Both animals had been originally captured and marked with medical cautery units (Winne et al. 2006. Herpetol. Rev. 37:52–54) at Ellenton Bay. The first *N. fasciata* was a male (SVL = 449 mm; 94 g), originally captured on 20 September 2005 in a plastic minnow trap within Ellenton Bay. It was captured three more times between 22 and 28 September 2005 at Ellenton Bay, prior to being captured 22 months later on 21 July 2007, at Dry Bay (SVL = 488 mm; 102 g). The second snake was a female (SVL = 603 mm; 170 g), originally captured on 1 April 2003 in a box trap along a terrestrial drift fence surrounding Ellenton Bay as it attempted to enter the wetland following a previous extreme drought that lasted from 2000–2003 (Willson et al. 2006. Wetlands 26:1071–1078). This snake was recaptured at Dry Bay on 13 September 2007 (SVL = 802 mm; 486 g), 4 years and 5 months after its initial capture. These two snakes represented 4% (2 out of 56) individual *N. fasciata* captured at Dry Bay in 2007 by TML.

These observations provide the first unambiguous evidence that *N. fasciata* move long distances between wetlands in response to drought conditions. Whether this is a case of directed migration between known habitats or the chance outcome of undirected dispersal, remains unknown. The majority of the intervening habitat between Ellenton Bay and Dry Bay is forested and relatively undisturbed by development, and includes some (mostly temporary and dry during the 2006–2007 period) wetlands that could have been used during transit. However, in addition to > 3 km of distance, the route between Ellenton Bay and Dry Bay is bisected by a well-traveled two-lane highway (SC Hwy 125) and a large (> 5 m across, > 1 m deep) creek (Upper Three Runs Creek). The motivation required to traverse these obstacles (roads) and potential refuges (creek) suggests that these snakes may have been purposefully seeking refuge at Dry Bay. This interpretation is supported by the fact that other *Nerodia* use wetland complexes on a landscape scale; Copperbelly Watersnakes (*N. erythrogaster neglecta*) regularly move between ephemeral wetlands under normal environmental conditions (Roe et al. 2004. Biol. Conserv. 118:79–89). Additionally, at least three species of freshwater turtles have been documented moving between Ellenton Bay and Dry Bay in the past (Buhlmann and Gibbons 2001. Chelon. Conserv. Biol. 4:115–127). Neither snake has been recaptured at either location since 2007, leaving unresolved the question of whether the snakes attempted to return to Ellenton Bay when normal water levels resumed.

We thank J. Whitfield Gibbons, Michael E. Dorcas, and John H. Roe for commenting on the manuscript. Snakes were captured under scientific research permits 56-2003, 07-2004, G-05-03, G-06-04, and G-07-03 from the South Carolina Department of Natural Resources. Funding for this research was provided by the American Museum of Natural History (through a Roosevelt Memorial Fund awarded to TML) and the Savannah River Ecology Laboratory under Financial Assistance Award DE-FC09-96SR18-546 between the University of Georgia and the U.S. Department of Energy.

WILLSON** (e-mail: willsonj@vt.edu) and **CHRISTOPHER T. WINNE** (e-mail: ctwinne@uga.edu), Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA.

***PSEUDOLEPTODEIRA URIBEI* (Uribe's False Cat-eyed Snake). REPRODUCTION.** The genus *Pseudoleptodeira* is endemic to Mexico and presently includes two species. The more recently described species, *P. uribei*, is known from a small series of individuals collected in the state of Jalisco (Ramirez-Bautista and Smith 1992. Bull. Maryland Herpetol. Soc. 28:83–98) and subsequent reports on individuals from the states of Guerrero (García and Ceballos 1994. Field Guide to the Reptiles and Amphibians of the Jalisco Coast, Mexico. Fund. Ecol. Cuixmala, A.C., Inst. Biol. U.N.A.M., Mexico City, 184 pp.), Michoacán (Mijangos et al. 2007. Herpetol. Rev. 37:500), and Colima (Reyes-Velasco et al. 2009. Herpetol. Rev. 40:117–120). Many aspects of natural history remain enigmatic for this species. Herein we present, to the best of our knowledge, the first formal report of clutch size in a *P. uribei*.

On 6 July 2009 at 2308 h, we found a gravid female *P. uribei* dead on a road near the city of Ixlahuacán, municipality of Ixtlahuacán, Colima, Mexico (19.02558°N, 103.78031°W, datum WGS 84; elev. 309 m). Because of vehicular injuries we were unable to obtain a precise measurement of body size, but conservatively estimate that the animal was over 60 cm total length. The adult female *P. uribei* contained six undamaged eggs which when measured with a digital caliper following preservation in 10% formalin had a mean length of 28.05 mm (± 2.09 SD) and a mean width of 11.32 mm (± 1.67 SS). Our identification was verified by Jacobo Reyes-Velasco and the specimen and its eggs are deposited in the herpetological collection of the University of Texas at Arlington (UTA R-57503; Field ID, JAC 30668).

Collection and exportation were conducted under SEMARNAT license numbers FAUT-0015 and SGPA/DGVS/8002, respectively. Funding was provided by NSF grant DEB-0613802 to J. A. Campbell.

JEFFREY W. STREICHER (e-mail: streicher@uta.edu), **CHRISTIAN L. COX, COLEMAN M. SHEEHY III, MATTHEW J. INGRASCI,** and **RUBEN U. TOVAR**, Amphibian and Reptile Diversity Research Center, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA.

***REGINA RIGIDA* (Glossy Crayfish Snake). TERRESTRIAL MOVEMENT.** The overland movements and upland habitat use of wetland-associated reptiles has important conservation implications (Semlitsch and Bodie 2003. Conserv. Biol. 17:1219–1228). However, for many species, particularly snakes, we lack a basic understanding of spatial ecology and habitat use. *Regina rigida* is a poorly known species for which "observations of any kind would be of considerable value in understanding its biology" (Gibbons and Dorcas 2004. North American Watersnakes: A Natural History. Univ. Oklahoma Press, Norman. 438 pp.). *Regina rigida* is a highly aquatic species and although sporadic reports exist of the snake found in habitats considered uplands, specific reports regarding distance to the nearest body of water are lacking.

Herein we report five captures of *R. rigida* in pitfall or box traps associated with drift fences in areas relatively distant from aquatic habitats. On 12 June 2005, we captured a *R. rigida* (SVL = 224 mm) in Conecuh National Forest, Covington Co., Alabama, USA in a trap approximately 10 m from the nearest pond margin. On 19 June 2005, also in Conecuh National Forest, we captured a specimen (SVL = 236 mm) 135 m from the nearest seepage creek and 1180 m from the nearest pond margin. Based on the position of its capture, the snake was moving away from the seepage toward the pond. On 13 June 2009, we captured a specimen (SVL = 190 mm; AUM 34944) on Eglin Air Force Base, Okaloosa Co., Florida, USA. This site was 470 m from the nearest aquatic habitat, a small creek. However, as the snake was captured in a bucket on the opposite side of the drift fence from this creek, the snake was either returning to the creek from a more distant location or originally inhabited a different water body. On 14 Sept 1996, we captured a *R. rigida* on private land in Bienville Parish, Louisiana, USA. The nearest water source was an intermittent stream 460 m from the trap. The nearest permanent water source was Kepler Lake, 860 m from the trap. On 3 May 2006, we captured a specimen on Ft. Polk Army Base, Vernon Parish, Louisiana, USA. The box trap that captured this snake was 70 m from an intermittent stream. Together, these observations indicate that *R. rigida* occasionally undertake significant terrestrial movements, although the impetus for these movements remains unknown.

***RHABDOPHIS CHRYSARGOIDES* (Gunther's Keelback Snake). MATING BEHAVIOR.** Mating behavior in snakes can be conspicuous but the secretive nature of snakes in general renders mating observations infrequent. Publishing mating observations contributes to our understanding of timing and location of reproduction, reproductive behaviors such as mating aggregations, and possible correlates of mating behavior such as sexual size dimorphism (Rivas and Burghardt 2001. Anim. Behav. 62:F1–F6; Shuster and Wade 2003. Mating Systems and Strategies. Princeton Univ. Press. Princeton. 520 pp.).

On 5 July 2009 at ca. 1900 h, we found a pair of *Rhabdophis chrysargoides* copulating along a stream in the Lambusango Reserve on Buton Island, southeast Sulawesi, Indonesia (5.2125°N, 122.8764°E, datum WGS84; elev. 238 m). The pair was draped along branches ca.1.2 m above water over the streambank in rainforest with ca. 90% canopy cover. The snakes were intertwined only near the tail and cloaca and were facing away from one another. Sperm was abundantly visible at the cloacae. At ca. 2200 h the snakes were still copulating in the same position, at which time they were collected for measurements and photographed; they separated shortly thereafter. The weather that night was ca. 24°C and partly cloudy after a rainless day. At ca. 0630 h the following morning the snakes were found copulating in the bag. The snakes were sexed, measured, and released that morning at their point of capture. The female was much larger than the male (female: SVL = 545 mm; tail length = 145 mm; male: SVL = 392 mm; tail length = 126 mm).

Rhabdophis chrysargoides is frequently encountered along streams on Buton Island (Gillespie et al. 2005. Biotropica 37:279–290). Recently hatched juveniles have been encountered in this area between July and September (G. Gillespie, unpubl. data). To our knowledge, mating has not been observed in this species. July coincides with the cessation of the wet season in southeast Sulawesi (Fontanel and Chantefort 1978. Bioclimates of the Indonesian Archipelago. Institut Francaise de Pondicherry).

***SIBON ARGUS* (Blotched Snail Sucker). DIET.** The diet of *Sibon* spp. is reported to include mollusks (Solórzano 2004. Snakes of Costa Rica. Instituto Nacional de Biodiversidad, Santo Domingo de Heredia, Costa Rica. 791 pp.) and soft-bodied invertebrates (Greene 1997. Snakes: The Evolution of Mystery in Nature. Univ. California Press. Berkeley. 351 pp.). However, Solórzano (2002. Rev. Biol. Trop. 49:1111–1120) and Ryan and Lips (2004. Herpetol. Rev. 35:278) mention the consumption of centrolenid eggs by *S. argus* and Montgomery et al. (2007. Herpetol. Rev. 38:343) documented the consumption of *Cochranella albomaculata* for the closely related and sympatric *S. longifrenis*.

On 12 June 2006 at 2245 h, a male *S. argus* (SVL = 33.6 cm; 6.6 g) was found eating a clutch of *Agalychnis callidryas* eggs in vegetation overhanging a small temporary pond in El Valle de Antón, Coclé Province, Republic of Panamá (Fig. 1). Eight eggs were manually palped from the snake. Three adult male *A. callidryas* were seen within 3 m of the snake but no other egg masses were found. This pond only

FIG. 1. *Sibon argus* consuming an *Agalychnis callidryas* egg (UTADC 6246), El Valle de Antón, Coclé Province, Republic of Panamá.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

maintains water after significant rain events and dries completely during the dry season. Two digital photographs were taken and were deposited at the Amphibian and Reptile Diversity Research Center, University of Texas at Arlington (UTADC 6246–47). This is the first confirmation that *Sibon* spp. feeds on *A. callidryas* eggs (Ryan and Lips [*op. cit.*] suggested that this might be the case for *S. nebulatus*) and expands the species of frog eggs that are preyed upon by *S. argus*. This further suggests that amphibian eggs might provide an important component of the diet of *Sibon* spp.

We thank the National Science Foundation, the Smithsonian Tropical Research Institute, Hotel Campestre (El Valle de Antón, Panamá), researchers of the TADS project, and Autoridad Nacional del Ambiente for assistance, permission, and/or funding. We thank R. C. Jadin, J. W. Streicher, and J. A. Campbell for depositing the digital images at UTA.

***THAMNOPHIS ELEGANS* (Terrestrial Gartersnake). FEEDING BEHAVIOR, PREY SUBJUGATION BY DROWNING.** *Thamnophis elegans* has been reported to feed on a wide variety of invertebrate and vertebrate species including slugs, earthworms, fish, amphibians, birds, and small mammals (Stebbins 2003. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., New York, New York. 533 pp.). Compared to other prey taxa, predation on mammals poses serious risks to this species because of mammals' high activity levels and the presence of sharp claws and teeth. Although some populations of *T. elegans* regularly prey on small mammals, they are poor constrictors, using coiling to "pin" their prey, at which time ingestion of the struggling victim occurs (Gregory 1978. Can. J. Zool. 56:1967–1974). Because *T. elegans* lack any strong immobilization mechanisms (i.e., venom or efficient constriction) and are inefficient predators of mammals, selection may favor novel techniques for subjugating these potentially dangerous prey.

On 17 September 2009 at 1645 h, near the bank of a man-made pond in Logan, Utah, USA (41.720309°N, 111.845749°W, datum WGS84; elev. 1369 m), we observed an adult *T. elegans* (total length ca. 50 cm) attack a mouse (body length ca. 6–9 cm). The snake struck the mouse at the posterior end, just above the tail. The snake attempted to subdue the mouse by coiling. Although this behavior looks similar to the constricting behaviors exhibited by other snakes, *T. elegans* rarely kills its prey in these attacks and uses this behavior to subdue the prey long enough to ingest it live (Gregory et al. 1980. Herpetologica 36:87–93).

The snake continued this coiling behavior on the shore of the pond for approximately 1 min at which time it rolled into the pond with its prey. While in the water the mouse continued to struggle, often temporarily freeing itself from the snake's coils long enough to come to the surface for air. The snake, however, still retained the mouse at its hind end and the mouse was quickly re-submerged and wrapped up. The snake and its prey continued in this manner for 7 min, and after 2 min of complete submersion the mouse appeared to have drowned. During the entire predation event, the snake's head remained submerged under water. At the time the mouse stopped moving, we were able to see that the snake had at least two coils wrapped loosely around the mouse.

The snake remained wrapped around the mouse, with its head still submerged, for another 3 min as the current caused the pair to drift to the center of the pond. We then observed the snake swim towards shore pushing the dead mouse in front of it for 10 m. We were unable to continue the observations and it is unknown if the snake consumed the mouse.

Although it is not uncommon for *T. elegans* to prey upon mice and other small rodents, this is the first record of *T. elegans* killing its prey by drowning. Because *T. elegans* is often found near water (Stebbins, *op. cit.*), it is possible that this type of predatory behavior is more common than has previously been thought.

JOSEPH S. WILSON (e-mail: joseph.wilson@usu.edu) and **BRIAN G. GALL** (e-mail: brian.gall@usu.edu), Utah State University, Biology Department, 5305 Old Main Hill, Logan, Utah 84322, USA

***THAMNOPHIS FULVUS* (Central American Highland Gartersnake). DIET.** *Thamnophis fulvus* is a terrestrial and semi-aquatic highland snake that is restricted to Nuclear Central America (Köhler 2003. The Reptiles of Central America. Herpeton, Offenbach, Germany. 368 pp.). Almost no information has been reported regarding the diet or foraging ecology of *T. fulvus*, as is the case with a number of Mesoamerican congeners (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman. 332 pp.). Brodie et al. (1991. Biotropica 23:58–62) stated that *T. fulvus* was known to feed on *Bolitoglossa* (Caudata: Plethodontidae), and in feeding trials *T. fulvus* accepted both *B. rostrata* and *B. subpalmata*. In Honduras, this species is found in the vicinity of streams, as well as temporary and permanent ponds in highland areas in the southwestern portion of the country. McCranie and Wilson (2002. SSAR Contrib. Herpetol. 19:i–x, 1–625) indicated that an adult specimen from Zacate Blanco (erroneously cited as "Zacate Grande"), Depto. Intibucá, Honduras, regurgitated a single *Hypopachus barberi* (Anura: Microhylidae). In addition, they reported *T. fulvus* as abundant in a stream at the type locality (Depto. de Ocotepeque: El Chagüitón) of *Craugastor anciano* (Anura: Craugastoridae) where it "was probably preying on these frogs."

On 24 May 2008, we collected two specimens (UF 152960–61) of *T. fulvus* in a cattle pond (14.146537°N, 87.844239°W, datum WGS84; elev. 2160 m) about 5 × 12 m in size, located about 3.4 airline km NNW Guajiquiro, Depto. La Paz, Honduras. The adult male *T. fulvus* (UF 152960) contained two adult *Exerodonta catracha* (Anura: Hylidae; UF 152962–63), a small hylid endemic to the highlands of southwestern Honduras. The adult female *T. fulvus* (UF 152961) contained one *Hypopachus barberi* (UF 152967), three *E. catracha* (UF 152964–66), and some frog eggs attached to the latter specimens. At this location, *H. barberi* were observed either floating on the surface of the pond or, in the case of calling males, sitting in concealed positions along the pond's edge. *Exerodonta catracha* were found floating in the pond as well, and were also extremely abundant in the grass and trees around the pond. Both anuran species were remarkably plentiful at this site, apparently due to fact that the first heavy rain of the season fell the night prior to our visit.

TOWNSEND**, School of Natural Resources and Environment, University of Florida, Gainesville, Florida 32611-7800, USA, Centro Zamorano de Biodiversidad, Escuela Agrícola Panamericana Zamorano, Departamento de Francisco Morazán, Honduras (e-mail: jtwnsnd@ufl.edu).

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*. SSAR Herpetol. Circ. 37:1–84, gratis PDF available (http://www.ssarherps.org/pages/HerpCommNames.php); for Mexico as it appears in Liner and Casas-Andreu 2008, *Standard Spanish, English and Scientific Names of the Amphibians and Reptiles of Mexico*. Herpetol. Circ. 38:1–162), LOCALITY (use metric for distances and give precise locality data, including lat/long coordinates in **decimal degrees** and cite the map datum used), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author; curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Sabaj Pérez [ed.], 2010. *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology, an Online Reference*. Version 2.0 [8 November 2010]. Electronically accessible at http:///www.asih.org/node/204) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief and must adhere to format used in this section; these should provide a geographic context for the new record). Skip a line and give name and address in full—spell out state or province names—no abbreviations. Please include distance from nearest previously known record (provide a citation or refer to existing vouchered material to substantiate your report). If publishing specific locality information for a rare or endangered species has the potential to jeopardize that population, please consult with the Section Editor at time of record submission. If field work and/or specimen collection occurred where permits were required, please include permit number(s) and authorizing governmental authority in the text of the note.

Some further comments. The role of the "Standard Names" lists (noted above) is to standardize English names and comment on the current scientific names. Scientific names are hypotheses (or at least represent them) and as such their usage should not be dictated by a list, society, or journal.

Additionally, this geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens that have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality photograph (print, slide, or digital file) may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Photographic vouchers *must* be deposited in a university or museum collection along with complete locality data, and the photographic catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*; available from the SSAR Publications Secretary), subsequent issues of *Herpetological Review*, and other sources to make sure you are not duplicating a previously published record. The responsibility for checking literature for previously documented range extensions lies with authors. **Do not submit range extensions unless a thorough literature review has been completed.**

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: **Alan M. Richmond** (USA & Canada records only); **Jerry D. Johnson** (Mexico and Central America, including the Caribbean Basin); **Indraneil Das** (all Old World records); or **Gustavo J. Scrocchi** (South American records). Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Electronic submission of manuscripts is required** (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Schmitz, A., and T. Ziegler. 2003. Geographic distribution: *Sphenomorphus rufocaudatus*. Herpetol. Rev. 34:385.

CAUDATA — SALAMANDERS

***AMBYSTOMA MACULATUM* (Spotted Salamander)**. CANADA: QUÉBEC: Manicouagan Regional County Municipality: Uapishka (Monts Groulx) region, in roadside ponds along Route 389, the Québec-Labrador Highway. "Pond 1" is located 5.3 km W of Mont Provencher near highway km 336 (51.480°N, 68.224°W, NAD1983; elev. 414 m). "Pond 2" is located 4.2 km N of Relais Gabriel, near highway km 324 (51.359°N, 68.148°W, NAD1983; elev. 446 m). 19 May 2010. M. T. Jones and L. L. Willey. Verified by J. Martinez. Harvard University, Museum of Comparative Zoology (MCZ A-140250, A-140251 digital images). This site represents a northeasterly range extension of approximately 160 km NW of an observation near Godbout (also in Manicouagan RCM), and 430 km ENE of an observation near Lake Mistassini (Bider and Matte 1996. The Atlas of Amphibians and Reptiles of Québec. St. Lawrence Valley Natural

History Society, Ste-Anne-de-Bellevue, Québec), and well outside of several published range maps (e.g., NatureServe, http://natureserve.org; IUCN, http://www.iucnredlist.org/apps/-redlist/details/59064/0/rangemap). Considered with the above-mentioned Lake Mistassini and a report from the James Bay region (Ouellet et al. 2009. Herpetol. Cons. Biol. 4[2]:277–284), our observation provides additional evidence that *A. maculatum* may be widespread, but undersampled, in Québec north of 50°N. Twelve egg masses were observed in Pond 1 and eight egg masses were observed in Pond 2. *Lithobates sylvaticus* egg masses were abundant in both locations.

Permission to initiate amphibian research in the Monts Groulx was coordinated by Dominic Boisjoly of the Québec Ministère du Développement durable, de l'Environnement et des Parcs. Funding for travel to the Monts Groulx was provided by the Guy Waterman Alpine Stewardship Fund.

MICHAEL T. JONES (e-mail: mtjones@bio.umass.edu), and **LISABETH L. WILLEY,** Department of Environmental Conservation, University of Massachusetts, Amherst, Massachusetts 01003, USA (e-mail: lwilley@eco.umass.edu).

***AMBYSTOMA JEFFERSONIANUM* (Jefferson Salamander)**. USA: PENNSYLVANIA: Warren Co.: Spring Creek Township, 0.6 km W of junction of Route 426 and Cemetery Rd. (41.86730°N, 79.52540°W; WGS 84). 31 March 2006. Mark Lethaby. Verified by Stephen Rogers. Carnegie Museum of Natural History (CM 130415, 155785). First county record (Hulse et al. 2001. Amphibians and Reptiles in Pennsylvania and the Northeast. Cornell Univ. Press, Ithaca. xii + 419 pp.).

MARK LETHABY, Natural History Museum at the Tom Ridge Environmental Center, 301 Peninsula Drive, Erie, Pennsylvania 16505, USA; e-mail: mlethaby@verizon.net.

***AMBYSTOMA OPACUM* (Marbled Salamander)**. USA: GEORGIA: Bartow Co.: Pine Log Mountain Wildlife Management Area, 5.86 km ENE of intersection of Stamp Creek Rd. and State Rt. 411 (34.256697°N, 84.688281°W; WGS 84). 5 May 2010. Z. Felix. AUM AHAP-D 274, digital image. Verified by Craig Guyer. New county record (Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). One adult found under log in floodplain of Stamp Creek.

ZACH I. FELIX, Biology Department, Reinhardt University, Waleska, Georgia 30183, USA; e-mail: zif@reinhardt.edu.

***AMBYSTOMA TEXANUM* (Smallmouth Salamander)**. USA: ARKANSAS: Sevier Co.: 2.1 km W Lockesburg off St. Hwy 24 at roadside ditch (33.966712ºN, 94.202957ºW; WGS 84). 26 May 2002. H. W. Robison. Verified by S. E. Trauth. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 31568). New county record that fills a distributional gap in southwestern Arkansas among Howard (Robison and McAllister. 2007. Herpetol. Rev. 38:212), Little River, and Polk counties (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

***BOLITOGLOSSA MEXICANA* (Mexican Mushroom-tongued Salamander; Salamandra de Vientre Oscuro)**. HONDURAS: OCOTEPEQUE: El Mojonal (14.483333°N, 89.283333°W; WGS84, elev. 1350 m). 13 August 2008. James R. McCranie and Leonardo Valdés Orellana. Verified by Sean M. Rovito. USNM 573703. First record for Ocotepeque (McCranie 2007. Herpetol. Rev. 38:36) and first Pacific versant record for the species (McCranie and Wilson 2002. The Amphibians of Honduras. SSAR Contr. Herpetol. 19, x + 625 pp.). Closest known Honduran record is 2 km N of Santa Rosa de Copán, Copán (McCranie 2006. Smithson. Herpetol. Inform. Serv. 137:4), located about 65 km NNE of El Mojonal. The salamander was found at night on low vegetation within a coffee farm, originally in broadleaf forest.

JAMES R. McCRANIE, 10770 SW 164th Street, Miami, Florida 33157–2933, USA (e-mail: jmccrani@bellsouth.net); **LEONARDO VALDÉS ORELLANA**, Gerente General de "Hondufauna," Investigador Privado, Colonia América, Bloque 9, Casa 1806, Comayagüela, MDC, Honduras (e-mail: leovalor@hotmail.com).

***DESMOGNATHUS QUADRAMACULATUS* (Black-bellied Salamander)**. USA: VIRGINIA: Russell Co.: Clinch Mountain Wildlife Management Area, 6.4 km NW of intersection of Russell County Routes 733 and 613 (36.931505°N, 81.831927°W; WGS 84). 16 June 2010. Z. Felix. AUM AHAP-D 280, digital image. Verified by Carlos Camp. New county record (Mitchell and Reay 1999. Atlas of Amphibians and Reptiles in Virginia. Virginia Dept. of Game and Inland Fisheries, Richmond. 122 pp.). One adult found under rock at Twin Springs, northwest of Tumbling Creek. The presence of *D. quadramaculatus* at this site extends the species' range 20 km NW in Virginia, and apparently represents a rare case of sympatry with *Desmognathus welteri*, the Black Mountain Salamander (Mitchell and Reay, *op. cit.*).

ZACH I. FELIX, Biology Department, Reinhardt University, Waleska, Georgia 30183, USA; e-mail: zif@reinhardt.edu.

***EURYCEA GUTTOLINEATA* (Three-lined Salamander)**. USA: GEORGIA: Banks Co.: Wilson Shoals Wildlife Management Area, close to Grant Mill Rd 0.9 km NE of junction with Yonah Homer Road (34.40291°N, 83.58813ºW, WGS 84; elev. 289 m). 02 April 2009. Robert L. Hill. Verified by Graig Guyer. AUM AHAP-D 286. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. Univ. of Georgia Press, Athens. 575 pp.). Previously documented in adjacent Habersham, Hall, Jackson, and Stephens counties. One adult female (49 mm SVL) and one adult male (41 mm SVL) retrieved from inside shallow crevices in a man-made rock structure near edge of stream along Grant Mill Road. Male specimen photographed and both released.

ROBERT L. HILL, Department of Conservation and Research, Atlanta Botanical Garden, Atlanta, Georgia 30309, USA; e-mail: rhill@atlantabotanicalgarden.org

***NECTURUS MACULOSUS LOUISIANENSIS* (Red River Mudpuppy)**. USA: ARKANSAS: Grant Co.: 19.3 km SW Sheridan along Saline River backwater area (34.195901°N, 92.539814°W; WGS 84). 8 May 2003. H. W. Robison. Verified by S. E. Trauth. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 31566). New county record; helps fill a distributional hiatus between Dallas and Hot Spring counties (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

***PSEUDOTRITON RUBER VIOSCAI* (Southern Red Salamander)**. USA: ALABAMA: Escambia Co.: along County Road 4, 0.2 mi. E. of County Road 11 (31.067574°N, 86.807876°W; WGS84/NAD83). 06 March 1999. R. Birkhead and S. M. Boback. Verified by Craig Guyer. AUM 35176. New county record. Fills the distribution gap between populations of *P. r. vioscai* to the south in Santa Rosa and Okaloosa counties, Florida (Ashton and Ashton 1988. Handbook of the Reptiles and Amphibians of Florida, Part III. The Amphibians. Windward Publishing. 191 pp.), and the putative zone of *P. r. ruber* × *P. r. vioscai* intergradation to the north in Monroe and Conecuh counties, Alabama (Mount 1996. The Reptiles and Amphibians of Alabama. University of Alabama Press. xi + 347 pp.). Collected in roadside ditch.

ROGER D. BIRKHEAD, Alabama Science In Motion, Auburn University, Alabama 36849-5414, USA (e-mail: birkhrd@auburn.edu); **SCOTT M. BOBACK**, Dickinson College, Carlisle, Pennsylvania 17013, USA (e-mail: bobacks@dickinson.edu); **SEAN P. GRAHAM,** Department of Biological Sciences, Auburn University, Alabama 36849-5414, USA (e-mail: grahasp@auburn.edu).

***SIREN INTERMEDIA NETTINGI* (Western Lesser Siren)**. USA: ARKANSAS: Perry Co.: 3.2 km SE Hollis at roadside ditch along Bear Creek (34.874444°N, 93.110278°W; WGS 84). 2 June 2005. H. W. Robison. Verified by S. E. Trauth. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 31569). New county record; fills a distributional gap in the Ouachitas south of the Arkansas River between Conway and Yell counties (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

ANURA — FROGS

***ACRIS CREPITANS* (Northern Cricket Frog)**. USA: ARKANSAS: Grant Co.: 1.6 km E Poyen off St. Hwy 270 (34.320614°N, 92.624016°W; WGS 84). 16 September 2010. H. W. Robison. Verified by S. E. Trauth. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 31567). A new county record that completely fills small hiatus in central Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). This frog has now been documented from every county of the state.

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

***ACRIS CREPITANS* (Northern Cricket Frog)**. USA: GEORGIA: Gwinnett Co.: George Pierce Park: ca. 0.87 km from junction of SR 13/US 23 and George Pierce Park (34.05667°N, 84.05481°W; WGS 84; elev. 280 m). 18 April 2008. Robert L. Hill. Verified by John B. Jensen and Joseph R. Mendelson. AUM AHAP-D 285. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. Univ. of Georgia Press, Athens. 575 pp.). Previously documented in all surrounding counties. Three specimens of undetermined sex observed in leaf litter along edge of small stream parallel to gravel hiking trail ca.70 m from trail entrance closest to George Pierce Park at end of parking lot. Specimens photographed and released.

ROBERT L. HILL, Department of Research and Conservation, Atlanta Botanical Garden, Atlanta, Georgia 30309, USA; e-mail: rhill@atlantabotanicalgarden.org.

***ACRIS CREPITANS* (Northern Cricket Frog)**. USA: INDIANA: Vermillion Co.: Highland Township: (40.09627°N, 87.43305°W; WGS 84). 02 April 2010. Nathan Engbrecht. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2010j). New county record. Fills a distribution gap in western Indiana (Minton 2001. Amphibians and Reptiles of Indiana, 2nd ed., revised. Indiana Academy of Science. vii + 404 pp.). Two adults were observed in the vicinity of a small farm pond.

NATHAN ENGBRECHT, 135 Holmstedt Hall, Indiana University School of Medicine-Terre Haute, Indiana State University, Terre Haute, Indiana 47809, USA (e-mail: nengbrecht@indstate.edu); **SARABETH KLUEH** and **JASON MIRTL**, Wildlife Diversity Section, Indiana Department of Natural Resources Division of Fish and Wildlife, 553 East Miller Drive, Bloomington, Indiana 47401, USA (e-mail: sklueh@dnr.in.gov).

***CARDIOGLOSSA ALSCO* (NCN)**. CAMEROON: ADAMAWA PROVINCE: Gotel Mts., Tchabal Wadi (alternative names: Tchabel Ouade, Tchabal Gangroua, Chappal Waddi, Gangirwal – latter two in Nigeria), Cameroon – Nigeria border: 7.02921°N, 11.70576°E, 2010 m elev. 5 November 2009. Václav Gvozdík. National Museum, Prague, Czech Republic. NMP6V 74162. Verified by David C. Blackburn. Previously known from type locality on southern slopes of Tchabal Mbabo Mts. (Herrmann et al. 2004. Herpetozoa 17:119–125; Herrmann 2006. *In* IUCN 2010. IUCN Red List of Threatened Species. Version 2010.4. <www.iucnredlist.org>). Subadult, probably male (SVL 23.6 mm) collected from side of small stream fringing forest within montane grassland-pasture in early dry season, with occasional rain. Active on wet rock-ground close to small pool at 1930 h, shortly after dusk. Locality is ca. 50 km by air from type locality, but in different mountain system. Present locality on border between Cameroon and Nigeria, and occurrence in Nigeria, on western slopes of Gotel Mountains, where Gashaka Gumti National Park extends, assumed.

Specimen collected under permit issued by Cameroonian Ministry of Forestry and Wildlife and Ministry of Scientific Research and Innovation Nos. 1010/PRBS/MINFOF/SG/DFAP/SDVEF/SC and 0132/MINRESI/B00/C00/C10/C13.

VÁCLAV GVOŽDÍK, Institute of Animal Physiology and Genetics, Academy of Sciences of the Czech Republic, Rumburska 89, CZ 277 21 Libechov & National Museum, Department of Zoology, Cirkusova 1740, CZ 193 00 Prague, Czech Republic; e-mail: vgvozdik@email.cz.

***CARDIOGLOSSA SCHIOETZI* (Acha Tugi Long-fingered Frog)**. CAMEROON: ADAMAWA PROVINCE: Gotel Mts., Tchabal Wadi (alternative names: Tchabel Ouade, Tchabal Gangroua, Chappal Waddi, Gangirwal – latter two in Nigeria), Cameroon – Nigeria border (07.02921°N, 11.70576°E, 2010 m elev.). 5 November 2009. Václav Gvozdík. National Museum, Prague, Czech Republic. NMP6V 74164/1–4. Verified by David C. Blackburn. Previously known from several localities in the mountains of Cameroon and eastern Nigeria: Oshie-Obudu Ridge, Mount Mbam, Mount Oku (Amiet 1981. Ann. Fac. Sci. Yaoundé 28:117–131; Amiet and Schiøtz 2008. *In* Stuart et al. [eds.], Threatened Amphibians of the World. Lynx Ediciones, Barcelona/IUCN- The World Conservation Union, Conservation International and NaturServe, Washington, D.C. 148 pp.; Blackburn 2006. Herpetol. Rev. 37:486). Four adult males (SVL 23.7–24.9 mm) collected from side of small stream fringing forest within montane grassland-pastures in early dry season when

occasional rains occurred. Males calling from leaf litter on banks close to stream from dusk until at least 2200 h. New record extends known range by ca. 170 km NE from nearest locality on Mount Oku.

Specimens collected under permits issued by Cameroonian Ministry of Forestry and Wildlife and Ministry of Scientific Research and Innovation Nos. 1010/PRBS/MINFOF/SG/DFAP/SDVEF/SC and 0132/MINRESI/B00/C00/C10/C13.

***EUPHLYCTIS HEXADACTYLUS* (Indian Five-fingered Frog)**. BANGLADESH: DHAKA: Gazipur District: Demurpara village, Pubail (23.9559°N, 90.4548°E, 70 m elev.). Digital image deposited at Raffles Museum of Biodiversity Research ZRC(IMG) 1.33. First record from Gazipur District. 28 May 2010 at ca. 1900 h near residential area. Verified by Monirul H. Khan. In Bangladesh, reported from western parts of Padma River as well as southeast, including Barisal and Khulna. Confirmed report from Jahangirnagar University Campus, Savar, Dhaka (Kabir et al. 2009. Encyclopedia of Flora and Fauna of Bangladesh. Volume 25. Amphibians and Reptiles. Asiatic Society of Bangladesh, Dhaka. 204 pp.). Reported from Sundarban Reserve Forest (Reza et al. 2000. Froglog 4[2]:1–2). First locality record from Gazipur District and northernmost record for Bangladesh.

MD. SHARIF HOSSAIN SOURAV, Department of Botany, Jahangirnagar University, Dhaka 1342, Bangladesh (e-mail: nature.sourav@gmail.com); **JAYADITYA PURKAYASTHA**, HelpEarth, Lachitnagar, RNC path Guwahati 781007, Assam, India (e-mail: jaya_ditya@rediffmail.com).

***HYLA CHRYSOSCELIS* (Cope's Gray Treefrog)**. USA: ALABAMA: Lauderdale Co.: Butler Creek off Co Rd 61 (34.98659°N, 87.61431°W, WGS 84). 28 October 2010. Christina M. Schmidt and Sean P. Graham. Verified by Craig Guyer. Photo voucher AUM AHAP-D 295. New county record (Mount 1975. The Reptiles and Amphibians of Alabama. University Alabama Press, Auburn. 345 pp.).

CHRISTINA M. SCHMIDT, 101 Life Sciences Building, Auburn University, Alabama 35849, USA.

***LEPTODACTYLUS SAVAGEI* (Rana Grande de la Selva)**. HONDURAS: ATLÁNTIDA: Pico Bonito Lodge, ca. 15 km WSW of La Cieba (15.70°N, 86.90°W, WGS84; elev. 100 m). 14 August 2009. James R. McCranie and Leonardo Valdés Orellana. Verified by W. R. Heyer. USNM 573361. First record for Atlántida (McCranie 2006. Smithsonian Herpetol. Inform. Serv. 137:33). Extends the range ca. 65 km W of the closest previously known locality at Balfate, Colón. The adult female was collected at night in the water at the edge of a small man-made pond surrounded by secondary lowland rainforest, during a light rain about 1 h after dark.

LEONARDO VALDÉS ORELLANA, Gerente General de "Hondufauna," Investigador Privado, Colonia América, Bloque 9, Casa 1806, Comayagüela, MDC, Honduras (e-mail: leovalor@hotmail.com); **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157–2933, USA (e-mail: jmccrani@bellsouth.net).

***LITHOBATES CATESBEIANUS* (American Bullfrog)**. USA: NEBRASKA: Rock Co.: approx. 5.9 mi. NNW Newport in sandhill habitat (42.68011667°N, 99.37136111°W, WGS 84; elev. 679 m). 15 June 2004. Brian Hubbs. Verified by Travis Taggart. Los Angeles County Museum photo voucher LACM PC 1534. First county record (Ballinger et al. 2010. Amphibians and Reptiles of Nebraska. Rusty Lizard Press, Oro Valley, Arizona. 400 pp.; Fogell 2010. A Field Guide to the Amphibians and Reptiles of Nebraska. University of Nebraska, Lincoln. 158 pp.) Frog found in man-made farm pond.

BRIAN HUBBS, P.O. Box 26407, Tempe, Arizona 85285, USA; e-mail: tricolorbrian@hotmail.com.

***LITHOBATES PALUSTRIS* (Pickerel Frog)**. USA: ILLINOIS: Edgar Co.: Brouilletts Creek, 0.76 km SE of intersection of County Road 2225 E and County Road 1650 N (39.702885°N, 87.550654°W; WGS 84). 29 August 2010. Collected by NMK and AMD. Verified by C. A. Phillips. INHS 2010–12. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Natural History Survey Manual 8. 300 pp.). A subadult *L. palustris* was found under a log on a sandy streambank at approximately 1700 h.

NICHOLAS M. KIRIAZIS (e-mail: nmkiriazis@eiu.edu) and **ANDREW M. DURSO**, Eastern Illinois University, Department of Biological Sciences, Charleston, Illinois 61920, USA (e-mail: amdurso@gmail.com).

***MELANOPHRYNISCUS DEVINCENZII*.** PARAGUAY: ITAPÚA DEPARTMENT: District of Alto Vera: Kanguery, privately-owned reserve by Guyra Paraguay within the area delimited for the implantation of the San Rafael National Park (26.50833°S, 55.7825°W; WGS 84). 18 February 2009 and 22 April 2009. K. Núñez. Verified by D. Baldo. Museo Nacional de Historia Natural del Paraguay, San Lorenzo, Paraguay (MNHNP 11392, 11400). First record of *M. devincenzii* for Itapúa Department and second record for Paraguay. *Melanophryniscus devincenzii* is known in the departments of Rivera and Tacuarembó, northeastern Uruguay (Achaval and Olmos 2003. Anfíbios y Reptiles del Uruguay, 2nd ed. Graphis Impresora, Montevideo. 136 pp.; Langone 1995 "1994." Mus. Damaso Antonio Larrañaga Ser. Divulg. 5); Misiones and Corrientes provinces, northern Argentina (Baldo and Krauczuk 1999. Cuad. Herpetol. 13:101; Baldo and Basso 2004. J. Herpetol 38:393–403; Boeris et al. 2010. Check List 6:395–396); the Municipality of Sertão, Rio Grande do Sul, Brazil (Zanella et al. 2007. Check List 3:104); Guairá Department, south-central Paraguay (Airaldi et al. 2009. Check List 5:377–379).

This new locality is situated between the known sites of the Department of Guaira (75 km SE) and the Provinces of Misiones and Corrientes (123 km NE and 148 km NE, respectively).

The collecting license was granted by Secretaría del Ambiente (13/2008).

KARINA NÚÑEZ, Universidad Nacional de Asunción, Facultad de Ciencias Exactas y Naturales, Departamento de Biología, Ruta Mariscal Estigarribia km 11 (Campus Universitario), San Lorenzo, Paraguay; e-mail: ranitapy@hotmail.com.

***OSTEOPILUS SEPTENTRIONALIS* (Cuban Treefrog)**. USA: FLORIDA: Bradford Co.: Starke, 703 South Orange Street (29.94015°N, 82.115328°W; WGS84). 12 December 2009. Linda S. Stevenson. Verified by Melvin P. Gramke. Florida Museum of Natural History, University of Florida. UF 162973. First county record (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida; Somma 2009. *In* Nonindigenous Aquatic Species. USGS: http://nas.er.usgs.gov/queries/FactSheet.asp?speciesID=57). One adult collected from inside a mailbox on wall of a residence. Individual *O. septentrionalis* have been sighted at this locality from early 2009 through early 2010. This established population is adjacent to populations of *O. septentrionalis* in Alachua, Clay, and Duval (Jacksonville) counties, Florida, forming part of a northern invasion front in Florida, from Levy Co. on the Gulf Coast extending northeastward to Nassau Co. (Krysko et al. 2005. Herpetol. Rev. 36:85–87; Somma 2009, *op. cit.*; Wilson and Bechler

2010. Herpetol. Rev. 41:376). This is Entomology Contribution No. 1186, DPI, FDACS.

SCINAX GRANULATUS **(NCN)**. ARGENTINA: BUENOS AIRES: Partido de General Pueyrredon: Sierra de Los Padres (37.94028°S, 57.79472°W; WGS 84). 24 July 2010. L. E. Vega and P. J. Bellagamba. Verified by J. Faivovich. Herpetological Collection of Laboratorio Vertebrados, Departamento de Biología, Universidad Nacional de Mar del Plata, Mar del Plata, Buenos Aires, Argentina (UNMdP 1809–1810). First citation for the county and the southernmost record known for this species. This is the first documentation of this frog inhabiting mountain environments at 170 m elev. Present record extends the distribution of this frog 120 km to the SW from nearest known locality in Partido de General Madariaga in the Buenos Aires province (Barrasso and Cajade 2007. Herpetol. Rev. 38:99). The species was previously known from northeastern Argentina, south to Buenos Aires Province; Uruguay and Paraná, Santa Catarina, and Rio Grande do Sul, Brazil; expected in southern Paraguay (Frost 2010. Amphibian Species of the World: an Online Reference. Version 5.4 [8 April 2010]. Electronic database accessible at http://research.amnh.org/vz/herpetology/amphibia. American Museum of Natural History, New York). Barrasso and Cajade (2007, *op. cit.*) pointed out that Gallardo mentioned two specimens from Sierra de la Ventana, but the citation is not supported by voucher specimens. Two adults were captured under rocks. Another five individuals were found inactive under rocks.

SCINAX TRAPICHEIROI. BRAZIL: RIO DE JANEIRO: Municipality of Bom Jesus do Itabapoana: River Itabapoana bank (21.106424°S, 41.725598°W; SAD 69, elev. 139 m). 18 August 2006. Collected by A. L. Silveira. Museu Nacional / UFRJ, Rio de Janeiro, RJ, Brazil (MNRJ 42510). Verified by U. Caramaschi. The new record extends the known geographic distribution of species about 205 km NE from the closest previous record (Saquarema, ZUFRJ 6720–6723, Luna-Dias et al. 2009. Check List 5[2]:251–253), and constitutes the northern and western boundaries of this distribution. First record of *Scinax trapicheiroi* in the Atlantic Forest biome, a semideciduous seasonal forest. Species was previously known from municipalities of Rio de Janeiro, Maricá, Angra dos Reis (Ilha Grande), Mangaratiba (Ilha da Marambaia), Piraí and Saquarema, in Rio de Janeiro state, Brazil (Luna-Dias et al., *op. cit.*; Lutz 1954. Mem. Inst. Oswaldo Cruz 52[1]:155–197); all localities occur in area of dense ombrophile forest.

ADRIANO LIMA SILVEIRA, Setor de Herpetologia, Departamento de Vertebrados, Museu Nacional / Universidade Federal do Rio de Janeiro, Quinta da Boa Vista, São Cristóvão, CEP 20940-040, Rio de Janeiro, RJ, Brazil; e-mail: biosilveira@yahoo.com.br.

CROCODYLIA — CROCODILIANS

PALEOSUCHUS PALPEBROSUS **(Cuvier's Dwarf Caiman, Jacaré-paguá)**. BRAZIL: CEARÁ: Itapipoca Municipality: Sítio São José (03.1825°S, 39.4369444°W; WGS84). January–February 2005. F. H. C. de Lima. Collection of Herpetology of Núcleo Regional de Ofiologia (NUROF) - Universidade Federal do Ceará, Fortaleza, Brazil (CHUFC C045–C046). Verified by L. M. Verdade. First state record. The species was also photographed and registered by visual survey on Serra das Almas, Crateús Municipalty (03.345°S, 40.8861111°W; datum WGS84), located 260 km airline SW from Itapipoca, during January 2003. The species was previously known from basins of Amazonian (Colombia, Venezuela, Guianas, Bolívia, Paraguay and Brazil), Pantanal, Caatinga, and Atlantic Forest (Brazil) biomes (Carvalho 1951. Os Jacarés do Brasil. Arquivos do Museu Nacional, XLII:127–152; King and Burke 1989. Crocodilian, Tuatara, and Turtle Species of the World. Association of Systematics Collections, Washington, DC. 216 pp). In northeastern Brazil, the species was known from Grande River in the São Francisco River basin, state of Bahia (Carvalho, *op. cit.*), and recently from Atlantic Forest on João Pessoa Municipality, state of Paraíba (Santana et al. 2008. Biotemas 21[1]:75–84). Extends known distribution ca. 660 km airline NW from João Pessoa, and ca. 900 km airline SW of previously known range to the Rio Grande/Rio São Francisco. This is the first record of the species from streams in dune forests (Complexo Litorâneo), ca. 3 km from the seacoast, and is the northernmost distribution point in northeastern Brazil.

Tabosa s/n, 62500-000, Itapipoca, Ceará, Brazil; Doctorate fellowship of Fundação Cearense de Apoio ao Desenvolvimento Científico e Tecnológico-FUNCAP (e-mail: dancassiano@yahoo.com.br); **FRANCISCO HÉLIO COELHO DE LIMA** , Programa de Pós-Graduação em Desenvolvimento e Meio Ambiente (PRODEMA/UFC), Campus do Pici, Bloco 902, 60455-760, Fortaleza, Ceará, Brazil; Master Fellowship of Coordenação de Aperfeiçoamento de pessoal de Nível Superior-CAPES (e-mail: heliosbio74@yahoo.com.br); **DIVA MARIA BORGES-NOJOSA**, Universidade Federal do Ceará, NUROF-UFC, Campus do Pici, Bloco 905, 60455-760, Fortaleza, Ceará, Brazil (e-mail: dmbnojosa@yahoo.com.br).

TESTUDINES — TURTLES

APALONE SPINIFERA **(Spiny Softshell)**. USA: OHIO: Union Co.: Paris Township: Mill Creek at Swartzkopf Park in Marysville (40.24449°N, 83.37324°W; WGS 84). 16 July 2008. Jeffrey E. Dawson. Verified by Jeffrey G. Davis. Photo voucher in Cincinnati Museum Center, Geier Collections and Research Center (CMC HP 480). First vouchered record for the county (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contr. No. 10, Columbus. iv + 81 pp.). Several specimens photographed as they basked on large woody debris within the stream. Rausch (1947. Am. Midl. Nat. 38:434–442) reported obtaining one *A. spinifera*

from Union Co. for a survey of chelonian helminths. The turtle was collected while basking on a rock in the Big Darby Creek immediately upstream of U.S. Rte. 36/State Rte. 4 within the village of Milford Center (R. L. Rausch, pers. comm.). This specimen was not deposited as a voucher and subsequently was not included in later atlases of Ohio reptile distributions by Conant (1951. The Reptiles of Ohio. 2nd ed. Univ. Notre Dame Press, Notre Dame. 284 pp.) and Wynn and Moody (2006, *op. cit.*). Recent sightings of *A. spinifera* in the Union Co. section of Big Darby Creek indicate that the species continues to inhabit the area (J. G. Davis, pers. comm.). Both Mill Creek and Big Darby Creek are tributaries of the Scioto River, with the current record ca. 8.8 km NE (straight-line distance) of Rausch's collection site. I thank Robert L. Rausch and Jeffrey G. Davis for their insights and comments on this note.

***CHELYDRA SERPENTINA* (Snapping Turtle)**. USA: ILLINOIS: Whiteside Co.: IL-84, 0.21 km S Carroll-Whiteside county line (41.927920°N, 90.104456°W; WGS84). 24 May 2010. A. M. Durso. Verified by C. A. Phillips. Photographic voucher INHS 2010-8. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Natural History Survey Manual 8. 300 pp.). A live adult female *C. serpentina* was moved from the highway at 2000 h.

ANDREW M. DURSO, Eastern Illinois University, Department of Biological Sciences, Charleston, Illinois 61920, USA (e-mail: amdurso@gmail.com); **LORIN A. NEUMAN-LEE** , Utah State University, Department of Biology, Logan, Utah 84332, USA (e-mail: lorin215@gmail.com).

***CHRYSEMYS DORSALIS* (Southern Painted Turtle)**. USA: LOUISIANA: Union Parish: Upper Ouachita National Wildlife Refuge (32.89062°N, 92.09124°W; NAD83). 12 June 2010. John L. Carr and Lisa D. Brown. Verified by John L. Carr. University of Louisiana at Monroe Museum of Natural History (NLU 70659, 70660). New parish record (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press. 300 pp.). A gravid female *C. dorsalis* was captured on 08 June 2010. The two hatchling vouchers were obtained from a clutch of seven eggs laid on 12 June 2010 when oviposition was induced with oxytocin administered to the female. Collecting was done with U.S. Fish and Wildlife Service special use permit 42651-10-07 and Louisiana Department of Wildlife and Fisheries collecting permit LNHP-10-048.

LISA D. BROWN, Department of Biology, University of Louisiana at Monroe, 700 University Ave., Monroe, Louisiana 71209, USA; e-mail: brownld@warhawks.ulm.edu.

***GRAPTEMYS GEOGRAPHICA* (Northern Map Turtle)**. USA: OHIO: Fairfield Co.: Berne Township, Logan-Lancaster Rd. (U.S. Rte. 33 Business) ca. 50 m E of the Hocking River and ca. 5.8 km SE of Lancaster (39.67103°N, 82.56126°W; WGS 84). 1 June 2010. Jeffrey E. Dawson and Cheri L. Dawson. Verified by Jeffrey G. Davis. Photo voucher in Cincinnati Museum Center, Geier Collections and Research Center (CMC HP 5266). New county record (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contr. No. 10, Columbus. iv + 81 pp.) and the second record of this species from the Hocking River system, extending the range in this drainage ca. 90 river km from a historical record in Athens Co. (Conant 1951. Reptiles of Ohio. 2nd ed. Univ. Notre Dame Press, Notre Dame. vi + 284 pp.). This species has also been collected from neighboring Franklin, Licking, and Pickaway counties in central Ohio. Adult female found DOR.

JEFFREY E. DAWSON, Reptiles/Shores Region, Columbus Zoo and Aquarium, Powell, Ohio 43065, USA and Department of Biology, University of Nebraska at Kearney, Kearney, Nebraska 68849, USA; e-mail: dawsonje@lopers.unk.edu.

***GRAPTEMYS GEOGRAPHICA* (Northern Map Turtle)**. USA: ILLINOIS: Whiteside Co.: Mississippi River, 1.64 km SW jct. Riverfront Dr. and Great River Trail (41.925796°N, 90.127778°W; WGS84). 12 June 2010. L. A. Neuman-Lee. Verified by C. A. Phillips. Photographic voucher INHS 2010-9. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Natural History Survey Manual 8. 300 pp.). An adult female *G. geographica* was observed basking on debris in the river.

LORIN A. NEUMAN-LEE, Utah State University, Department of Biology, Logan, Utah 84332, USA (e-mail: lorin215@gmail.com); **ANDREW M. DURSO**, Eastern Illinois University, Department of Biological Sciences, Charleston, Illinois 61920, USA (e-mail: amdurso@gmail.com).

***GRAPTEMYS PSEUDOGEOGRAPHICA* (False Map Turtle)**. USA: ILLINOIS: Carroll Co.: Thomson, Main St., 0.22 km E jct. Lewis Ave. (41.958503°N, 90.109141°W; WGS84). 18 September 2010. A. M. Durso. Photographic voucher INHS 2010-10. An adult female crossing the road at 1600 h. Whiteside Co.: Mickelson's Landing sand prairie, 0.69 km NW jct. Covell Rd. and IL-84 (41.918912°N, 90.117005°W; WGS84). 9 June 2008. L. A. Neuman-Lee. Photographic voucher INHS 2010-11. New county record. An adult female was observed nesting on a sand prairie. Both vouchers verified by C. A. Phillips.

LORIN A. NEUMAN-LEE, Utah State University, Department of Biology, Logan, Utah 84332, USA (e-mail: lorin215@gmail.com); **ANDREW M. DURSO**, Eastern Illinois University, Department of Biological Sciences, Charleston, Illinois 61920, USA (e-mail: amdurso@gmail.com).

***MACROCHELYS TEMMINCKII* (Alligator Snapping Turtle)**. USA: TENNESSEE: Tipton Co.: Densford Bar Mississippi River Mile 757 Pecan Point Quad (35.410308°N, 90.026275°W, NAD 83). 15 June 2004. Robert Colvin. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19066). New county record (Scott and Redmond 2008. Atlas of Reptiles in Tennessee, Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available from http://www.apsu.edu/reptatlas/frames_file.htm, accessed 4 October 2010). One individual found by a fisherman. Air temperature at collection was 35°C.

Voucher image made under the authority of the Tennessee Wildlife Resources Agency; field work supported by State Wildlife Grant (SWG) funding under the authority of the U.S. Fish and Wildlife Service.

ROBERT COLVIN, Tennessee Wildlife Resources Agency Region I, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA; e-mail: Rob.Colvin@.tn.gov

***MELANOCHELYS TRICARINATA* (Tricarinate Hill Turtle)**. INDIA: MADHYA PRADESH: Kanha National Park: Phuta Tal (22.2777°N, 80.6425°E, ca. 600 m elev., WGS84) 28 June 2009. Digital image voucher, ZRC (IMG) 2.128. Photographed by Durgesh Kumar Singh. Verified by Indraneil Das. Species known from relatively narrow sub-Himalayan band across NE India, Nepal, and Bangladesh. Nearest population in Chaibassa, in Jharkhand State, ca. 550 km to northeast (Das 2009. Chelonian Res. Monogr. 5:025.1–0.25.5). Individual observed crossing dirt road opposite Phuta Tal at 0740 h, and went under dry leaf litter on forest floor.

DURGESH KUMAR SINGH, Taj Safaris, Banjaar Tola, Mukki, Post Baihar, Balaghat District, Madhya Pradesh, India; e-mail: durgesh.singh@gmail.com.

***PSEUDEMYS CONCINNA* (River Cooter)**. USA: GEORGIA: Baldwin Co.: ca. 3 km E and 4 km N of Milledgeville (33.120173°N, 83.182872°W; WGS84). 14 October 2010. Sergio Paiitucci Saieh. GCH 5345. Verified by John B. Jensen. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Single sub-adult collected in pitfall trap on forest floor in mixed pine-deciduous forest near Lake Laurel.

SERGIO PAIITUCCI SAIEH (e-mail: sergio_patituccisaieh@ecats.gcsu.edu) and **DENNIS PARMLEY**, Department of Biological and Environmental Sciences, Georgia College & State University, Milledgeville, Georgia 31061, USA.

***STERNOTHERUS MINOR PELTIFER* (Stripe-necked Musk Turtle)**. USA: MISSISSIPPI: Perry Co.: De Soto National Forest (31.194439°N, 89.129217°W; NAD83). 24 November 2010. Donald J. Newman III and James R. Lee. Verified by Robert L. Jones. Mississippi Museum of Natural Science (MMNS 17439). New county record. Although the species is known from eleven other counties statewide, its distribution within the Pascagoula River system appears to be limited (Iverson 1977. Cat. Am. Amphib. Rept. 195:1–2; McCoy et al. 1978. Herpetol. Rev. 9:109). We also searched *Herpetological Review* records from 1967–September 2010, Mississippi Department of Wildlife, Fisheries, and Parks collection records, and all museums on www.herpnet.org).

DONALD J. NEWMAN III (e-mail: dnewman@tnc.org.) and **JAMES R. LEE**, The Nature Conservancy, Camp Shelby Joint Forces Training Center, CSJFTC-ENV Building 622, Camp Shelby, Mississippi 39407, USA.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. USA: GEORGIA: Cherokee Co.: Reinhardt University campus, 0.42 km NNW of intersection of State Routes 108 and 140 (34.321556°N, 84.555367°W; WGS 84). 21 April 2010. Z. Felix. AUM AHAP-D 278, digital image. Verified by Craig Guyer. New county record (Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). One adult found in pond.

ZACH I. FELIX, Biology Department, Reinhardt University, Waleska, Georgia 30183, USA; e-mail: zif@reinhardt.edu.

***TERRAPENE CAROLINA* (Eastern Box Turtle)**. USA: ALABAMA: Autauga Co.: Found dead on road, along Hwy 82 near the town of Prattville (32.441850°N, 86.413117°W; WGS84/NAD83). 19 May 2010. R. Birkhead. AHAP-D-265 –266, digital images. Chambers Co.: I-85 near the town of Valley (32.832150°N, 85.204133°W; WGS84/NAD83). 8 October 2009. R. Birkhead. AUM 33164, DOR. Madison Co.: Caught live across from the intersection of Slatemill Rd and Bell Rd in southwest Huntsville (34.610871°N, 86.577766°W; WGS84/NAD83). 13 July 2010. D. O'Halloran and S. Dery. AHAP-D-262–264, digital images. All verified by Craig Guyer. New county records (Mount 1996. The Amphibians and Reptiles of Alabama. University of Alabama Press. xi + 347 pp.). *Terrapene carolina* is assumed to occur statewide; however, verified records are lacking for many Alabama counties.

ROGER D. BIRKHEAD, Alabama Science In Motion, Auburn University, Alabama 36849-5414, USA (e-mail: birkhrd@auburn.edu); **DAN O'HALLORAN**, Alabama Science In Motion, University of Alabama Huntsville, Alabama 35899, USA (e-mail: do0001@uah.edu); **SAMUAL G. DERY,** 14000 Hermosa Drive, Huntsville, Alabama 35803, USA (e-mail: atlpunkrocker@yahoo.com).

***TRACHEMYS SCRIPTA* (Pond Slider)**. USA: GEORGIA: Cherokee Co.: Reinhardt University campus, 0.42 km NNW of intersection of State Rts. 108 and 140 (34.321556°N, 84.555367°W; WGS 84). 21 April 2010. R. Mansfield. AUM AHAP-D 279, digital image. Verified by Craig Guyer. New county record (Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Three juveniles dip-netted from pond.

ZACH I. FELIX (e-mail: zif@reinhardt.edu)**, RACHEL MANSFIELD,** and **DANIELLE GLANZER**, Biology Department, Reinhardt University, Waleska, Georgia 30183, USA.

SQUAMATA — LIZARDS

ANOLIS EUSKALERRIARI. COLOMBIA: LA GUAJIRA: Urumita Municipality: Tres Picos farm, Serranía del Perijá (10.459083°N, 72.95725°W; datum Bogotá WGS 84). 12 November 2009. J. E. Carvajal-Cogollo and V. A. Bernal-González. Colección de Reptiles. Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Bogotá, Colombia (ICN 12075). Verified by R. A. Moreno-Arias and O. V. Castaño-Mora. First country record. This species was known only from Mesa Turik in Venezuela (Barros et al. 1996. Breviora [504]:1–30). Extends species range 28.5 linear km W of type locality "Serranía del Perijá" (Barros et al. 1996, *op. cit.*; Poe 1998. Herpetol. Monogr. 12:192–236).

Submitted by: **JUAN E. CARVAJAL-COGOLLO** (e-mail: juancarvajalc@gmail.com), and **VLADIMIR A. BERNAL-GONZÁLEZ,** Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Apartado Aéreo 7495, Bogotá D.C., Colombia (e-mail: vlacho83@gmail.com).

***HELODERMA HORRIDUM* (Mexican Beaded Lizard)**. MÉXICO: DURANGO: Municipality of Tamazula: 3 km N Jala (24.9333°N, 106.9500°W; WGS84), elev. 650 m. 14 September 2007. Iván T. Ahumada. Verified by Héctor Eliosa León. Colección Herpetológica de la Escuela de Biología, Benemérita, Universidad Autónoma de Puebla (EBUAP 2103). First record for the state and extends the known range ca. 60 km NNE from the closest known locality at Costa Rica, 16 mi. S of Culiacan (UIMNH 36201). The lizard was found in tropical deciduous forest. We thank Chris Phillips for providing information from the UIMNH collection.

IVÁN T. AHUMADA-CARRILLO, Centro Universitario de Ciencias Biológicas y Agropecuarias, Universidad de Guadalajara, Zapopan, Jalisco, México (e-mail: lepidus320@hotmail.com); **CARLOS A. HERNÁNDEZ-JIMÉNEZ**, Laboratorio de Sistemática y Recursos Naturales, Escuela de Biología, Universidad Autónoma de Puebla, Edificio 112 A Ciudad Universitaria C.P. 72570 Puebla, México (e-mail: acaltetepon22@gmail.com); **URI OMAR GARCÍA-VÁZQUEZ**, Laboratorio de Herpetología, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, México, D.F. 04510, México (e-mail: urigarcia@gmail.com).

***HEMIDACTYLUS FRENATUS* (Asian House Gecko)**. SOUTHWEST PACIFIC: COOK ISLANDS: AITUTAKI: Arutanga Wharf (18.83°S, 159.75°W). First island record and approximate year of establishment. 5 October 1995. B. J. Gill, Auckland Museum (AIM

LH1855–7). Verified by Tom Trnski, Auckland Museum. Aitutaki is the second-most visited island in Cook Group, located 260 km N of main island of Rarotonga. No previous records on Aitutaki; known in Rarotonga since 1987 (Gill 1998. Tuhinga 10:151–157). BJG spent a week on Aitutaki (4–10 October 1995) and searched at many sites across main island (including jetties at Vaipae and Tautu) and on some of its lagoon islets, and found none other than three caught at wharf buildings in main town (Arutanga) on west coast. AHW visited Aitutaki in July 2000 and found species widespread along western side of island. Scarcity of species in 1995, their presence then at island's main wharf, and abundance in 2000 at many sites, seem to fix 1995 as approximate year of arrival at Aitutaki, presumably in cargo.

B. J. GILL, Auckland Museum, Private Bag 92018, Auckland, New Zealand (e-mail: bgill@aucklandmuseum.com); **A. H. WHITAKER**, 270 Thorpe-Orinoco Road, R.D. 1, Motueka, New Zealand (e-mail: whitaker@ts.co.nz).

***HEMIDACTYLUS TURCICUS* (Mediterranean House Gecko)**. PORTUGAL: MOURÃO: ca. 38.3847°N, 07.3444°W. 26 July 2010. Collected by Luis Ceríaco, Centro de Estudos de História e Filosofia da Ciência, Universidade de Évora. Specimen and photographic vouchers deposited at Colecção de Animais em formol of the Museu de Ciências Naturais da Escola Secundária André de Gouveia (MCN/MB/AC/V/39). Verified by Ana Pires. Species known from several localities, nearest population at western margin of Guadiana (Mateus and Jacinto 2010. *In* Loureiro et al. [coord.], Atlas dos Anfíbios e Répteis de Portugal, pp. 130–131. Esfera do Caos Editores, Lisboa). Collected and photographed on village wall, at ca. 2230 h. Individuals abundant on village walls, where groups of 2–3 seen at a time, especially after 2100 h.

LUIS MIGUEL PIRES CERÍACO, Projecto "Salvem as Osgas!" and Centro de Estudos de História e Filosofia da Ciência, Universidade de Évora; Bairro do Bacelo, Rua do Viveiro nº 5D, 7005-638 Évora, Portugal (e-mail: luisceriaco@netcabo.pt); **MARIANA PIMENTEL MARQUES**, Projecto "Salvem as Osgas!" and Escola de Ciências e Tecnologias, Universidade de Évora.

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)**. USA: ARKANSAS: Jefferson Co.: Jefferson (Sec. 11, T4S, R11W; 34.380556°N, 92.163889°W; WGS84). 6 October 2010. Joe M. Fowler. Verified by S. Trauth. Arkansas State University Museum of Zoology (ASUMZ 31565). New county record partially filling a distributional gap in southeastern Arkansas (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). This specimen was from a reproducing population as it was a hatchling or very young juvenile.

JOE MIKE FOWLER, 2525 Whitewood Drive, Sherwood, Arkansas 72120, USA; e-mail: jfowle98@yahoo.com.

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)**. USA: TEXAS: Ward Co.: 900 block Franklin Ave., 0.6 km E St. Hwy 18 (31.593345°N, 102.892995°W; NAD83). 23 April 2008. Matthew Anderson. Oklahoma State University Stillwater (OSUS R6137). Winkler Co.: 2100 block East Ave., 0.5 km N St. Hwy 302 (31.88346°N, 103.01183°W; NAD 83). 5 May 2009. Matthew Anderson. OSUS R6144. Both specimens verified by Stanley Fox. New county records (Dixon 2000. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 421 pp.). The presence of juveniles and adults at the former residence indicates a breeding population. At the latter site (apartment complex), a single adult was located on a brick wall; the only sighting made by MLA during three months living at this locale. These records represent a further expansion of this species' range immediately north of the Pecos River into more arid and sparsely populated counties of west Texas; the closest proximate locality is southward across the Pecos River in Pecos Co. (Dixon 2000, *op. cit.*).

MATTHEW L. ANDERSON (e-mail: matt.anderson@okstate.edu) and **DUSTIN T. LYNCH**, Zoology Department, Oklahoma State University, Stillwater, Oklahoma 74078, USA; **CHRIS T. McALLISTER**, Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu).

***MANTHEYUS PHUWUANENSIS* (Phu Wua Rock Agama)**. LAOS: BOLIKHAMXAY PROVINCE: Pakkading District: Nam Kading National Protected Area (18.3717°N, 104.1625°E, WGS 84; 450 m elev.). 27 May 2009. Kiangsack Bouakhasith and Chris D. Hallam. Verified by James A. Schulte II. North Carolina State Museum of Natural Sciences (NCSM 77720). Adult male in crag of rock overhang in large boulder pile ca. 15 m from small, permanent, flowing stream in hill evergreen forest, at dusk. Female observed in syntopy but not captured. Third known locality for species with small range and district record. Originally described from Phu Wua Wildlife Sanctuary in Nong Khai Province, Thailand (Manthey and Nabhitabhata 1991. Sauria 13:3–6) and reported from Phou Khao Khouay National Protected Area (= National Biodiversity Conservation Area) in Bolikhamxay Province, Thaphabat District, Laos (Ananjeva and Stuart 2001. Russ. J. Herpetol. 8:165–170; Manthey and Manthey 2005. Reptilia 10:26–31). New record ca. (straight-line) 25 km from type locality in Thailand and 100 km from Laos locality. The species is geographically restricted to a small area near the Mekong River in these two countries, where it occurs on rock ledges, boulder piles, and caves in evergreen forest.

STUART**, North Carolina State Museum of Natural Sciences, Raleigh, North Carolina 27601, USA (e-mail: bryan.stuart@ncdenr.gov); **SOMPHOUTHONE PHIMMACHAK** and **NIANE SIVONGXAY**, Department of Biology, Faculty of Sciences, National University of Laos, Vientiane, Laos.

***PLESTIODON ANTHRACINUS* (Coal Skink)**. USA: PENNSYLVANIA: Venango Co.: Cranberry Township, State Game Land 45 (41.33046°N, 79.61633°W; WGS 84). 24 June 2007. Natural History Museum at the Tom Ridge Environmental Center (TREC R- 00020). Vouchers collected at two additional Venango Co. (TREC R- 00046, 00047). All specimens collected by Mark Lethaby and verified by Peter Lindeman. First vouchered county records. Extends the species range in Pennsylvania 25 km W from the nearest record in Forest Co. (Hulse et al. 2001. Amphibians and Reptiles in Pennsylvania and the Northeast. Cornell Univ. Press, Ithaca, New York. xii + 419 pp.). Collections made under Pennsylvania Fish and Boat Commission Scientific Collector Permit 184.

MARK LETHABY, Natural History Museum at the Tom Ridge Environmental Center, 301 Peninsula Drive, Erie, Pennsylvania 16505, USA; e-mail: mlethaby@verizon.net

***PLESTIODON FASCIATUS* (Common Five-lined Skink)**. USA: GEORGIA: Cherokee Co.: Reinhardt University campus, 0.62 km NE of intersection of State Rts. 108 and 140 (34.319640°N, 84.547130°W; WGS 84). 17 April 2010. K. Thompson. AUM AHAP-D 276, digital image. Verified by Craig Guyer. New county record (Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). One juvenile under cover in field.

ZACH I. FELIX, Biology Department, Reinhardt University, Waleska, Georgia 30183, USA (e-mail: zif@reinhardt.edu); **KATHY THOMPSON**, Language Research Center, Georgia State University, Atlanta, Georgia, USA.

***PLESTIODON SKILTONIANUS UTAHENSIS* (Great Basin Skink)**. USA: WYOMING: Lincoln Co.: on west bank of Bear River, 6.0 km N of Cokeville (42.13769ºN, 110.97446ºW; NAD27). 6 May 2010. Henry J. Vogel, Charlotte E. Matthews, and Leslie A. Schreiber. Verified by Christopher Phillips. Illinois Natural History Survey (INHS 2010d). New state record (Baxter and Stone 1985. Amphibians and Reptiles of Wyoming, 2nd ed. Wyoming Game and Fish Department, Cheyenne, Wyoming. 137 pp.). One juvenile was found 10 m from a former dammed area on the Bear River, underneath a piece of tin. Temperature was 2.2°C when found, though had been sunny earlier in the day. Another juvenile was found on 7 May 2010, 6.4 km NE of first specimen under a rock on a ridge, 275 m from water. A genetic sample was obtained from this individual.

CHARLOTTE E. MATTHEWS (e-mail: charlotte.matthews@wgf.state.wy.us), **HENRY J. VOGEL**, and **LESLIE A. SCHREIBER**, Wyoming Game and Fish Department, 3030 Energy Lane, Casper, Wyoming 82604, USA.

***SPHAERODACTYLUS DUNNI* (NCN)**. HONDURAS: GRACIAS A DIOS: Región La Mosquitia, Reserva de Biósfera Río Platano, Raudal Kiplatara (15.583472°N, 84.933589°W; WGS84), 230 m elev. 20 July 2003. Jorge A. Ferrari. Verified by Konrad Klemmer. SMF 86283. First record for Gracias A Dios, with the closest reported locality being near Trujillo, ca. 115 km to the WNW (Harris and Kluge 1984. Occas. Pap. Mus. Zool. Univ. Michigan 706:1–59). The lizard was found during daytime inside a rotten tree trunk in rainforest.

GUNTHER KÖHLER, Forschungsinstitut und Naturmuseum Senckenberg, Senckenberganlage 25, 60325 Frankfurt a.M., Germany (e-mail: gkoehler@senckenberg.de); **JORGE A. FERRARI**, Organización de Rescate y Protección de Reptiles y Anfibios de Honduras, Tegucigalpa, Honduras (e-mail: herpetoking@yahoo.com).

SQUAMATA — SNAKES

***AGKISTRODON CONTORTRIX* (Copperhead)**. USA: TEXAS: Rockwall Co.: 32.823360°N, 96.490687°W; WGS84) 10 September 2005. Matthew D. Broxson. Verified by Carl J. Franklin, The University of Texas at Arlington Reptile and Amphibian Diversity Research Center (UTA DV1001). New county record (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M University Press, College Station, Texas. 421 pp.) Copperheads have been documented in all adjacent counties but not from Rockwall Co. (Dixon 2000, *op. cit.*). This may reflect the small size of the county, the prevalence of urbanization throughout most of the county, and the fact that a large portion of the county is open water.

MATTHEW D. BROXSON, Department of Life, Earth and Environmental Sciences, West Texas A&M University, Box 60808, Canyon, Texas 79016, USA.

***AGKISTRODON PISCIVORUS* (Cottonmouth)**. USA: TENNESSEE: Tipton Co.: Hwy 54 approximately 1 mile W of the Hatchie River in the Turnpike 7.5-minute USGS quad (35.3357°N, 89.2922°W; NAD 83). 17 June 2009. Collected by Robert Colvin. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19067). New county record (Scott and Redmond 2008. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available from http://www.apsu.edu/reptatlas/frames_file.htm, accessed 4 October 2010).

Voucher image made under the authority of the Tennessee Wildlife Resources Agency; field work supported by State Wildlife Grant (SWG) funding under the authority of the U.S. Fish and Wildlife Service.

ROBERT COLVIN, Tennessee Wildlife Resources Agency Region I, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA; e-mail: Rob.Colvin@tn.gov.

***CHARINA BOTTAE* (Rubber Boa)**. USA: CALIFORNIA: San Luis Obispo Co.: Montaña de Oro State Park: Valencia Peak Trail (35.2636417°N, 120.87425°W; Google Earth; elev. 326 m). 02 June 2010, 1045 h, ~16°C air, total length ca. 46 cm, in an area of rocky shale outcrops and coastal scrub vegetation. Steve C. Schubert. Verified by Richard F. Hoyer. Natural History Museum of Los Angeles County voucher photographs (LACM-PC 1515–1517).

This appears to be the first documented report of *Charina bottae* within San Luis Obispo Co. There are a few earlier sight reports during the past several decades within or near Montaña de Oro State Park; the most recent of these was in 2006, when a boa was found on the Coon Creek Trail in the riparian zone, but the observer lacked a camera to document the find and the snake was not collected (B. Stafford, California Department of Fish and Game, pers. comm.).

STEVEN C. SCHUBERT, P.O. Box 6002, Los Osos, California 93412, USA; e-mail: s_schub1@msn.com.

***COLUBER* (=*MASTICOPHIS*) *TAENIATUS* (Striped Whipsnake)**. USA: WYOMING: Sweetwater Co.: Flaming Gorge National Recreation Area, less than 1 km W of US Highway 191, 2–3 km N of the Utah border (41.020028°N, 109.431500°W; WGS84). 5 July 2010. Deborah Ambrose and Zachary Pohlen. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2010s [digital photographs]). First verified record for this species in Wyoming (Baxter and Stone 1985. Amphibians and Reptiles of Wyoming, 2nd ed. Wyoming Game and Fish Department, Cheyenne, Wyoming. 137 pp.). The Striped Whipsnake is known to occur in Utah, just south of the Wyoming border. Although the species has been observed previously in the state by Jan Roth, it was not formally verified or considered a native Wyoming species (Zack Walker, Wyoming Game and Fish Department, pers. comm.). This observation formalizes the previous sighting and provides reason for the state of Wyoming to assign it a native species status. Two living individuals were observed on the same day within 1–2 km of each other, both on unpaved roads. One large adult specimen was observed on the side of Canyon Road/Forest Service Road 26. The second specimen (INHS 2010s) was observed shortly thereafter sunning on Flaming Gorge Road/County Road 33 and was captured for photographs and released.

KAYLAN A. HUBBARD, Wyoming Cooperative Fish & Wildlife Research Unit, Department of Zoology and Physiology, University of Wyoming, Laramie, Wyoming 82071, USA; e-mail: khubbar4@uwyo.edu.

***CROTALUS HORRIDUS* (Timber Rattlesnake)**. USA: TENNESSEE: Haywood Co.: approximately 2.1 km S of Highway 54 off of Herbert Willis Road and located in the Turnpike 7.5-minute USGS quad (35.562810°N, 89.428480°W; NAD 83). 2 June 2010. Robert Colvin. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19070). New county record (Scott and Redmond 2008. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available from http://www.apsu.edu/reptatlas/frames_file.htm, accessed 4 October 2010).). One individual found by a farmer on the John Willis farm. Temperature at collection was 26.1°C.

Collection made under the authority of the Tennessee Wildlife Resources Agency; field work supported by State Wildlife Grant (SWG) funding under the authority of the U.S. Fish and Wildlife Service.

ROBERT COLVIN, Tennessee Wildlife Resources Agency Region I, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA; e-mail: Rob.Colvin@tn.gov.

***DRYMARCHON COUPERI* (Eastern Indigo Snake)**. USA: GEORGIA: Dodge Co.: SR 117, 0.85 km S George S Walker Road (31.937967°N, 83.178675°W; WGS84, elev. 60 m). 23 October 2010. W. Kellner. Verified by Kenneth L. Krysko. Photographic voucher UF 163246. First record for county (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.).

WILLIAM S. KELLNER, 4851 West Blue Indigo Lane, Beverly Hills, Florida 34465, USA; **KILEY V. BRIGGS, JAVAN M. BAUDER,** and **DIRK J. STEVENSON,** The Orianne Society, Indigo Snake Initiative, 579 Hwy 441 South, Clayton, Georgia 30525, USA.

***DRYMARCHON MELANURUS* (Central American Indigo Snake)**. HONDURAS: VALLE: Isla del Tigre, close to Amapala (13.2898°N, 87.6555°W, WGS84; elev. 10 m). 14 July 2010. Alexander Gutsche, James R. McCranie, and Leonardo Valdés Orellana. Verified by James R. McCranie. USNM 565805. First record for Valle, ca. 35 km SW of the closest known locality, 20 km WNW of Choluteca, Choluteca (UNAH 4232)). The snake was killed by a local in a residential neighborhood.

Field work of A. Gutsche was supported by the Adolf and Hildegard Isler Foundation.

***LICHANURA TRIVIRGATA GRACIA* (Desert Rosy Boa)**. USA: NEVADA: Clark Co.: Newberry Mountains, Christmas Tree Pass (35.261667°N, 114.746944°W; WGS 84). 30 May 2010. Paul Lynum and Tony Boudreau. Verified by Carol L. Spencer. Museum of Vertebrate Zoology (MVZ 263987). First state record. Adult female found on the road at 1118 h. This is the sixth specimen found in the Newberry Mountains by Paul Lynum—none of the previous animals were deposited as voucher specimens. Closest known localities for *L. trivirgata* are in the Cerbat and Hualapai Mountains of Mohave Co., Arizona (Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 533 pp.; UAZ 42143, 47322, 55611). Using pattern as an indicator of relationships, this population is most similar to those in western Arizona rather than geographically proximate populations of *L. t. gracia* in southeastern California. Although the Colorado River serves as a formidable barrier to gene flow between California/Nevada and Arizona populations of some reptiles (Lamb et al. 1989. Evolution 43:76–87; Mulcahy et al. 2006. Mol. Ecol. doi: 10.1111/j.1365-294X.2006.02892.x), it may not be insurmountable; snakes from the southeasternmost population of *L. t. gracia* in the Black Mountains, Imperial Co., California, phenotypically resemble those from Arizona more closely than they do those occurring elsewhere in California.

MITCHELL MULKS, Department of Ecology and Evolutionary Biology, University of California at Santa Cruz, Santa Cruz, California 95064, USA; e-mail: mulks@biology.ucsc.edu.

***OPHEODRYS VERNALIS* (Smooth Greensnake)**. USA: PENNSYLVANIA: Erie Co.: Amity Township, State Game Land 162 (41.9739°N, 79.8421°W; WGS 84). 05 October 2005. Mark Lethaby. Verified by Peter Lindeman. Natural History Museum of the Tom Ridge Environmental Center (TREC R- 00003). First vouchered county record (Hulse et al. 2001. Amphibians and Reptiles in Pennsylvania and the Northeast. Cornell Univ. Press, Ithaca, New York. xii + 419 pp.).

MARK LETHABY, Natural History Museum at the Tom Ridge Environmental Center, 301 Peninsula Drive, Erie, Pennsylvania 16505, USA; e-mail: mlethaby@verizon.net.

***PANTHEROPHIS ALLEGHANIENSIS* (Eastern Ratsnake)**. USA: GEORGIA: Dawson Co.: Amicalola Falls State Park: approximately 2.5 km from junction of Top of the Falls Rd. and Amicalola Park Rd (34.56138°N, 84.24833°W; WGS 84, elev. 595 m). 30 September 2009. Snakes and Lizards from the Bumdeling Wildlife Sanctuary Region of Bhutan: Review of Herpetofaunal Information and New Country Records

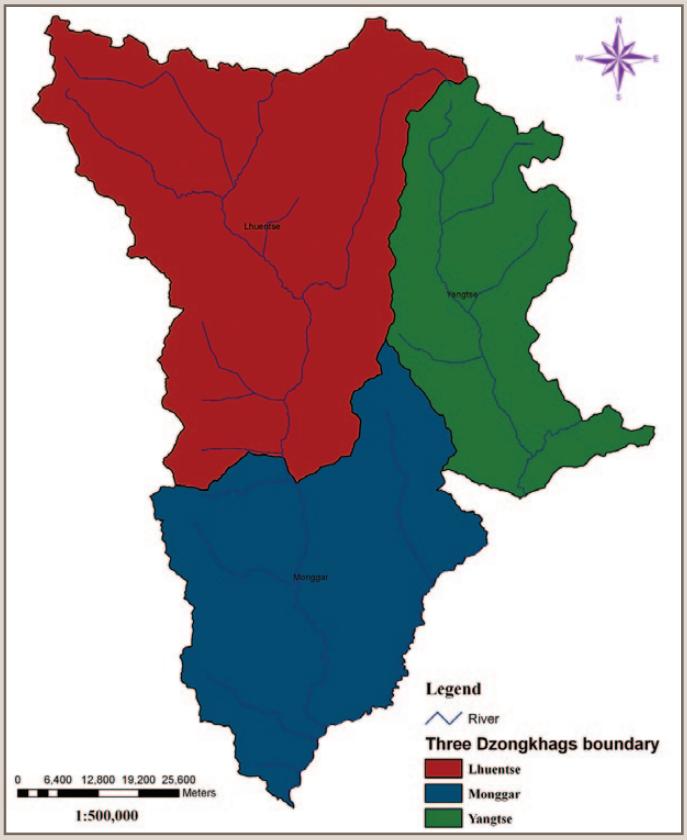

FIG. 1. Map showing study area located in northeastern Bhutan. Map source: Dzongkhag Statistics Office, Trashiyangtse.

Bumdeling Wildlife Sanctuary is one of 10 protected areas in Bhutan and is located to the northeast. It is bordered by the Tawang District of Arunachal Pradesh, India, in the east, and by China to the north. The Sanctuary covers developmental blocks, locally called Gewogs, on the districts of Lhuentse, Mongar, and Trashiyangtse, and is spread over an area of 1965 km^2 and has an altitudinal range from 1500 m in the south to 6400 m in the north (Fig. 1). Three main rivers cross the Sanctuary including the Kulong Chhu in the east, the Khoma Chhu in the west, and the Sheri Chhu in the south. These originate in the alpine and snow-capped mountains of the Sanctuary and ultimately drain into the Brahmaputra, in Assam State, India.

This mountainous sanctuary is dissected by steep-sided valleys and is subject to erosion and flooding during the summer. In some cases, land use practices exacerbate the process of land transformation. The Kulong Chhu River system, which meanders through the eastern stretch of the Sanctuary, erodes land and deposits sand, gravel, and cobbles at the base of the flood plain of the Bumdeling Valley. Further up, the alpine landscape is replete with signs of glacial activity, such as cirques, moraines, and glacial lakes.

The Bumdeling Wildlife Sanctuary was established in 1994, and started functioning in 1998 with the establishment of a Sanctuary Head Office for human resources and other infrastructure. However, in the last 10 years of management, there has been no mention of reptile conservation programs or diversity study records within the management plan. With the exception of the Royal Manas National Park, none of the protected areas of Bhutan has reports of their reptile diversity.

The lack of herpetological studies for the Sanctuary is not surprising, as the herpetological information for Bhutan as a whole is scanty. Biswas (1976) reported on three agamas, one of which was new—*Calotes bhutanensis*. The next two reports were published by Bustard (1979, 1980), explicitly on crocodilians. Bauer and Günther (1992) prepared a preliminary list of the herpetofauna of the Kingdom of Bhutan. They based their list on specimens collected by a 1972 expedition of the Basel Natural History Museum (Switzerland) to Bhutan. These authors reported seven families and 18 species, including a new scincid lizard. Das and Palden (1999) reported on a herpetofaunal collection assembled while conducting Bhutan's first workshop on herpetological techniques for staff of the protected areas of Bhutan, at the Royal Manas National Park. They reported seven amphibians (all new records for Bhutan) of three families (one megophryid, one bufonid, and five ranids), three geckos, one agamid, two scincids, one typhlopid, three colubrids, and two elapids. The current literature records bring the total herpetofauna of Bhutan to 39 species (Table 1).

To this list we can add 10 more species records from new specimens at the collection of Royal Manas National Park laboratory. The list is presented below (Table 1).

Considering the unpublished records, the total number of species of herpetofauna known from Bhutan is 49. With this report, several more species are added to this list.

With the financial support from the Bhutan Trust Fund for Environmental Conservation (based in Thimphu), Bumdeling Wildlife Sanctuary conducted a rapid survey of its reptiles between April and December 2008. Testudines and Crocodilia are absent in the area, but snakes and lizards were collected from

the Sanctuary. Collections were made mostly from the southern belt of the Sanctuary, an area classified as sub-tropical to warm broadleaved forest (Grierson and Long 1983). The altitudinal range of the current work ranged from 614 m, at Sheripam, Mongar to 2143 m at Barigang, Trashiyangtse.

Collections were opportunistic, by me and colleagues, sometimes supplemented by people encountering animals and reporting to us. Hand searching, turning over of logs and boulders, looking inside crevices and tree holes, and searching along creeks were some other methods employed. Occasional interviews of local residents, as to where these animals could be located, were also done. A monetary reward for locals who captured live specimens was another important way of obtaining specimens. To avoid the loss of dead animals, people were informed that they would be compensated even if they preserved dead animals. Many specimens were collected encountered on roads.

Due to restrictions on killing of animals, most specimens were released after photography, with only important ones retained and preserved. For several species (e.g., *Bungarus bungaroides*), only photographs could be taken. Species determinations were made using standard identification guides. Features of scalation and morphometric measurements were recorded. For specimens recorded only through photo vouchers, these have been given an accession number and are labeled 'photographic specimen' throughout this report. Preserved specimens are housed at the collection of the Bumdeling Wildlife Sanctuary Museum, Trashiyangtse, Bhutan, using a numbered system. For each preserved specimen, locality and microhabitat data, date and time (Bhutan Standard Time) of collection, altitude, and measurements are presented. Data on pholidosis for ventrals using the Dowling system and midbody scale at the half of the ventrals and subcaudals, excluding the final spine (for those juvenile specimens) is also given for snake specimens. Measurements were taken with a steel tape measured to the nearest 1 mm. A Garmin Etrek GPS was used to record locations of all specimens. Abundant species such as *Calotes versicolor* were closely observed only for the first 2–3 animals, while subsequent individuals were visually identified without capture. The identification references used in the field include Das (2002), Smith (1935, 1943), and Whitaker and Captain (2004).

SPECIES ACCOUNTS

LIZARDS

Family Agamidae

Calotes versicolor, Daudin, 1802. Photographic specimen BWS SPRO-L1. Sheripam, Mongar District, 869 m. 1100 h. 15 April 2008. Photographed on fallow land near Sherichu River. Most abundant lizard encountered. Multiple specimens photographed at several locations. Photos show color variation. *Remarks:* Reported by Günther and Bauer (1992) from Wangdiphodrang, and by Biswas from Samdrup Jongkhar (eastern Bhutan). Also reported from Gelephu town, Sarpang District by Das and Palden (1999). Common in southern Bumdeling Wildlife Sanctuary.

Calotes jerdonii, Günther, 1870. BWS KPRO-L4. Khoma, Lhuentse District, 1200 m. 1130 h. 29 May 2008. From trail 3 m from stream, trying to cross trail facing hill side. *Measurements*: SVL

90 mm; tail length 215 mm. *Remarks:* New record for Bhutan. Second specimen found at Wanglawa, Trashiyangtse District on 10 June 2008, at 1125 h.

Japalura variegata, Gray, 1853. BWS CKHQ-L2. BWS head office, Trashiyangtse District, 1761 m. 1214 h. 30 September 2008. From parking lot of Bumdeling Wildlife Sanctuary Head Office. Found hunting insects. *Measurements*: SVL 67 mm; tail length 160 mm. Second specimen obtained at Serzhong Range Office, Serzhong, Mongar District. Photographed (BWS SPRO-L5) on 24 July 2008 at 1213 h. *Remarks*: Common in southern part of sanctuary.

Family Gekkonidae

Hemidactylus platyurus, Schneider, 1792. Photographic specimen BWS SPRO-L9. from Serzhong, Mongar District, 1,540 m. 2133 h. 3 August 2008. Photographed at night on side of footpath. Photographic specimen BWS SPRO-L12, from Serzhong, Mongar District, 1500 m. 1913 h. 17 May 2008. Photographed on wall of agriculture extension agent of Gewog. *Remarks:* Reported by Günther and Bauer (1992) from Wangdiphodrang District, western Bhutan. Common.

Family Scincidae

Asymblepharus cf. ***sikkimensis,*** Blyth, 1854. Photographic specimen BWS SPRO-L7. Serzhong, Mongar District, 1,500 m. 1140 h. 2 August 2008. Found on edge of farm, over rock. Photographic specimen BWS SPRO-L8. Serzhong, Mongar District, 1545 m. 1211 h. 13 August 2008. Found entering quarter of Range Officer. *Remarks*: Common.

Sphenomorphus sp. Photographic specimen BWS KPRO-L1. Khoma, Lhuentse District, 1170 m. 1613 h. 24 April 2008. At edge of playground of Khoma Lower Secondary School.

SNAKES

Family Colubridae

Ahaetulla prasina, Boie, 1827. BWS OPA-S5. Pakadrang (below Yadi), Mongar District, 973 m. 1530 h. 21 September 2008. One of two road-killed specimens found at this locality. *Measurements*: SVL 930 mm; tail length 520 mm. *Pholidosis*: Ventrals 197; subcaudals 167; midbody scale rows 15; anal plate single. *Remarks*: New record for Bhutan.

Amphiesma sieboldii, Günther, 1860. Photographic specimen BWS DPRO-S14. Dungzam, Bumdeling, Trashiyangtse, District, 1903 m. 1000 h. 15 July 2008. Found by a heath worker in his garden, 30 m from Kulongchu River. Individual with broken tail kept in laboratory for one week, where it laid three eggs. Released at office complex. *Remarks*: New record for Bhutan. Second individual caught in kitchen garden of nearby house on 19 July 2008, at ca. 0830 h.

Amphiesma sp. BWS DPRO-S8. Kwankang (Cheng), Bumdeling, Trashiyangtse District, 1990 m. 1330 h. 24 June 2008. Collected 10 m from Kulongchu River while crossing footpath towards river. *Measurements*: SVL 765 mm; tail length 200 mm. *Pholidosis*: Ventrals 168; subcaudals 67; midbody scale rows 15; anal plate single. *Remarks*: Probably new record for Bhutan and possibly an undescribed species.

Boiga cyanea, Duméril, Bibron & Duméril, 1854. Photographic specimen BWS SPRO-S4. Shingdogor (above Yarab), Sherimung, Mongar District, 1929 m. 1529 h.15 April 2008. Video clip (7.2. megapixels digital camera) confirms identity of species. Found in high, cool, broad-leaved forest, close to a small stream. *Remarks*: New record for Bhutan.

Boiga multifasciata, Blyth, 1861. BWS CKHQ-S11. Choetenkora town, Trashiyangtse District, 1761 m. 1159 h. 27 September 2008. Caught by municipal staff while entering housing colony. Preserved after photography. *Measurements*: SVL 529 mm; tail length 115 mm. *Pholidosis*: Ventrals 230; subcaudals 117; midbody scale rows 21; anal plate single. *Remarks*: New record for Bhutan. Species recorded from several locations. BWS KPRO-S8, photo taken by Chief Forest Officer of Bumdeling Wildlife Sanctuary, from Khoma Zam, Lhuentse District, on 13 June 2007, at 0617 h. On 7 July 2008, at 1800 h, a laboratory technician in Trashiyangtse hospital collected a specimen (BWS CKHQ-S9) from Bimkhar, Trashiyangtse. On 28 November 2008, at 1330 h, a photographic specimen (BWS KPRO-S12) found near Range Office of Khoma, Lhuentse. Another photographic specimen (BWS SPRO-S10) brought by school teacher from near house at Bimkhar, Trashiyangtse. Snake caught on evening of 15 August 2008.

Boiga ochracea, Günther, 1868. BWS SPRO-S11. Serzhong (Mangzhing), Mongar District, 1766 m. 1030 h. 9 June 2008. Specimen found in maize field. *Measurements*: SVL 860 mm; tail length 238 mm *Pholidosis*: Ventrals 238; subcaudals 100; midbody scale rows 21; anal plate single. *Remarks*: Reported by Bauer and Günther (1992), from Phuntsholing.

Coelognathus radiatus, Boie, 1827. BWS OPA-S12. Rollong, Trashigang District, 694 m. 1500 h. 11 November 2008. Juvenile on roadside, ca. 150 m from perennial stream and close to road construction labor office. *Measurements*: SVL 320 mm; tail length 30 mm. *Pholidosis*: Ventrals 244; subcaudals 91; midbody scale rows 19; anal plate single. *Remarks*: New record for Bhutan.

Dendrelaphis cyanochloris, Wall, 1921. Photographic specimen BWS OPA-S3. Palangphu, Mongar District, 763 m. 1030 h. 4 October 2008. Found dead on road. *Remarks*: New record for Bhutan.

Dinodon septentrionalis, Günther, 1864. BWS DPRO-S6. Trammar, Bumdeling, Trashiyangtse District, 1809 m. 1030 h. 10 June

2008. Specimen found under bark of fallen *Alnus nepalensis* tree, above farm road. *Measurements:* SVL 965 mm; tail length 225 mm. *Pholidosis*: Ventrals 210; subcaudals 72; midbody scale rows 17; anal plate single. *Remarks*: New record for Bhutan.

Dryocalamus cf. ***davisonii,*** Smith, 1943. Photographic specimen BWS DPRO-S12. Betsamang, Bumdeling, Trashiyangtse District, 1903 m. 0800 h. 29 June 2008. Found in litter compost in farm. Photographed alive and released. *Remarks*: New record for Bhutan. Another photographic specimen (BWS DPRO-S13) collected on 1 July 2008 by villager from Trammar, Bumdeling, Trashiyangtse District, from farm road, at ca. 0830 h.

Oligodon albocinctus, Cantor, 1839. BWS CKHQ-S11. Choetenkora, Trashiyangtse District, 1760 m. Collected in 2003 by management staff, and preserved in Visitor Center. *Measurements*: SVL 665 mm; tail length 185 mm. *Pholidosis*: Ventrals 196; subcaudals 63; midbody scale rows 19; anal plate single. *Remarks*: New record for Bhutan. A second specimen (photo specimen BWS SPRO-S10) provided by staff of Serzhong Park Range, Mongar. According to collectors individual was found eating eggs, behind Basic Health Unit office of Serzhong developmental block, on 25 May 2008, at 1400 h. A third specimen photographed by Park Range Officer of Khoma. Individual found at Serphu, Khoma Village, Lhuentse district, on footpath at ca. 1000 h on 1 December 2008.

Oligodon cinereus, Günther, 1864. Photographic specimen BWS SPRO-S15. Serzhong, Mongar District, 1541 m. Found on footpath leading to village, where it was killed by farmer and brought to Range Office in Serzhong. Photograph taken by staff of Range Office on 25 June 2008, at 1643 h. *Remarks*: New record for Bhutan.

Oligodon dorsalis, Gray, 1834. Photographic specimen BWS SPRO-S19. Serzhong, Mongar District, 1541 m. 1831 h. 24 August 2008. Photo taken by staff of Range Office; found in roadside meadow. *Remarks*: Reported by Das and Palden (1999) from Royal Manas National Park, Sarpang.

Oligodon sp. BWS CKHQ-S7. Choetenkora, Trashiyangtse District, 1,818 m. 1135 h. 27 June 2008. Specimen found on grassy lawn. *Measurements*: SVL 653 mm; tail length 150 mm. *Pholidosis*: Ventrals 191; subcaudals 66; midbody scale rows 19; anal plate single. *Remarks*: New record for Bhutan. Two other photographic specimens (BWS DPRO-S1 and S5) from Tshaling, Trashiyangtse. First killed by farmer on 4 June 2008, second in a paddy field on 9 June 2008.

Oreocryptophis porphyracea, Cantor, 1839. BWS CKHQ-S2. Bumdeling Wildlife Sanctuary Headquarters, Trashiyangtse District, 1761 m. 1530 h. 15 April 2008. At door of residence of Chief Forest Officer of Sanctuary, ca. 100 m from Kulongchu River. *Measurements*: SVL 625 mm; tail length 125 mm. *Pholidosis*: Ventrals 199; subcaudals 62; midbody scale rows 19; anal plate divided. *Remarks*: New record for Bhutan. Another road kill of about the same size (BWS CKHQ-S1) collected from entry gate to town of Trashiyangtse, in early morning (0600 h) of 16 May 2008. Staff of Serzhong Park Range, Mongar provided photo of another specimen on 21 October 2008, from Muhoong, Mongar District, found on trail near village, at 1530 h.

Orthriophis cantoris, Cantor, 1839. BWS SPRO-S12. Pangtala, Mongar District, 1790 m. 1230 h. 10 June 2008. In cultivated maize field. *Measurements*: SVL 995 mm; tail length 235 mm. *Pholidosis*: Ventrals 209; subcaudals 76; midbody scale rows 19; anal plate single. *Remarks*: New record for Bhutan. Small specimen (photographic specimen BWS SPRO-S12) also collected from maize field at Jabgang, same District and developmental block, on 18 May 2008.

Orthriophis taeniurus, Cope, 1861. BWS KPRO-S1. Khoma, Lhuentse District, 1200 m. 1300 h. 19 April 2008. Near Range Office wall. Measurements: SVL 1300 mm; tail length 300 mm. Pholidosis: Ventrals 238; subcaudals 93; midbody scale rows 23; anal plate divided. Remarks: New record for Bhutan. Another specimen (photographic specimen BWS KPRO-S3) found in Lhuentse town, Lhuentse District, moving towards cave on road. A picture of third specimen taken by Land Survey officials at 1200 h on 30 August 2008, at Baptong in same district and block.

Pseudoxenodon macrops, Blyth, 1854. BWS DPRO-S9. Sisikang, Bumdeling, Trashiyangtse District, 1959 m. 1400 h. 24 June 2008. On edge of Sisikang Stream, tributary of Kulongchu River, specimen was heading towards river. Flattened neck several times. *Measurements*: SVL 740 mm; tail length 195 mm. *Pholidosis*: Ventrals 165; subcaudals 64; midbody scale rows 17; anal plate divided. *Remarks*: Reported by Bauer and Günther (1992), from Phuntsholing. A few days later, second specimen brought by farmer from Bumdeling, Trashiyangtse. On 2 November 2008, juvenile entered our campsite at Bumdeling, Trashiyangtse at 1411 h. Specimen preserved and kept in the laboratory.

Ptyas korros, Schlegel, 1837. BWS OPA-S11. Rollong, Trashigang District, 694 m. 1100 h. 4 November 2008. Juvenile crossing road ca. 8 m away from perennial stream and 100 m from a settlement. *Measurements*: SVL 330 mm; tail length 142 mm. *Pholidosis*: Ventrals 181; subcaudals 140; midbody scale rows 17; anal plate divided. *Remarks*: New record for Bhutan.

Ptyas nigromarginatus, Blyth, 1854. Photographic specimen BWS DPRO-S2. Bumdeling, Trashiyangtse District, 1885 m. 1130 h. 4 June 2008. Found slithering over *Cyathea* fern, below farm road, ca. 500 m from Kulongchu River. *Remarks*: Reported by Bauer and Günther (1992). First specimen recorded as roadkill between Trashiyangtse to Mongar on 7 November 2007, at Yadi, Mongar. Third specimen recorded from Bimkhar, Trashiyangtse, on 15 June 2008, at 1130 h, killed by Bhutan Power Corporation staff when on power line at Trashiyangtse. Fourth

specimen found dead at 7 km point from Yongkola on road from Thimphu, Mongar, on 21 September.

Rhabdophis himalayanus, Günther, 1864. Photographic specimen BWS SPRO-S13. Tingtibi, Zhemgang District (not recorded in BWS), 1945 m. Coordinates 27°15'10"N, 91°16'24"E. Information and photograph courtesy of D. B. Gurung, College of Natural Resources, Lobesa, Punakha. Not found in the project area. *Remarks:* New record for Bhutan.

Sibynophis collaris, Gray, 1853. BWS CKHQ-S13. Baychen, Trashiyangtse District, 1799 m. 1800 h. 30 September 2008. Collected between school and footpath leading to Baychen village, at 200 m from Berzing Stream. *Measurements*: SVL 450 mm; tail length 225 mm. *Pholidosis*: Ventrals 181; subcaudals 115; midbody scale rows 17; anal plate single. *Remarks*: New record for Bhutan. Photographic specimen (BWS SPRO-S2) found at Kilikhar, near Mongar, on 29 April 2008 at 1614 h, on road, ca. 300 m from stream. Third specimen found at Muroongdrang, Serzhong, Mongar, on 15 May 2008. Individual dead on road to Serzhong, probably killed by locals. In yet another incident, three individuals (photographic specimen BWS SPRO-S12) killed by farmer behind the Matron's Quarter (near girls' dormitory) at Trashiyangtse Lower Secondary School. Five juveniles found under weed heaped around base of gourd plant, in a garden.

Trachischium cf. ***laeve,*** Peracca, 1904. Photographic specimen BWS SPRO-S3. Serzhong, Mongar District, 1540 m. 1641 h. 4 February 2008. Accidentally killed by a resident while gardening. *Remarks*: New record for Bhutan.

Trachischium sp. BWS CKHQ-S6. Choetenkora, Trashiyangtse District, 1758 m. 1000 h. 15 June 2008. Specimen found in lawn of Bumdeling Wildlife Sanctuary Head Office complex. *Measurements*: SVL 325 mm; tail length 50 mm. *Pholidosis*: Ventrals 134; subcaudals 36; midbody scale rows 13; anal plate single. *Remarks*: Not referrable to *T. guentheri* or *laeve*. New record for Bhutan.

Family Elapidae

Bungarus bungaroides, Cantor, 1839. Photographic specimen BWS SPRO-S11. Serzhong, Mongar District, 1541 m. 0900 h. 5 August 2008. Collected by farmer, photographed and released. *Remarks*: New record for Bhutan. Another specimen (Photographic specimen BWS OPA-S7) found dead on road, near Korila Forest Management Unit Office, Mongar, on 21 September 2008, at 1400 h.

Naja kaouthia, Lesson, 1831. BWS SPRO-S5. Sheripam, Mongar District, 869 m. 1705 h. 15 May 2008. Killed by farmer when trying to enter hen coop. *Measurements*: SVL 828 mm; tail length 242 mm. *Pholidosis*: Ventrals 184; subcaudals 57; midbody scale rows 21; anal plate single. *Remarks*: New record for Bhutan. Another specimen (BWS SPRO-S8) found along Yadi-Serzhong Road, Mongar on 22 May 2008. Found struggling to escape crow attack near dry causeway of road and seen entering basement of causeway. In yet another incident, road-killed specimen (BWS SPRO-S16) was found at Sherichu, on 8 July 2008.

Ophiophagus hannah, Cantor, 1836. Photographic specimen BWS OPA-S5. Gomkora, Trashiyangtse District, 822 m. 1700 h. 5 November 2007. Specimen killed by farmer. Second specimen, a dead juvenile (BWS KPRO-S13), collected at Khoma School, Lhuentse District, September 2008. Students killed the animal. Measurements and scales count could not be taken due to poor condition of specimen. Third specimen, a juvenile (BWS OPA-S13), from Chumdu area, Trashiyangtse, 1703 m. 1200 h. 23 October 2008. Specimen obtained by Mr. Sherub (an ornithologist). *Measurements*: SVL 480 mm; tail length 87 mm. *Pholidosis*: Ventrals 254; subcaudals 30+ (could be counted only up to 30); midbody scale rows 17; anal plate single. *Remarks*: Reported at Manas Valley by Biswas (1975).

Sinomicrurus macclellandii, Reinhardt, 1844. BWS OPA-S8. Ngatshang, Mongar District, 1755 m. 1500 h. 21 September 2008. Cross the road near the Ngatshang Basic Health Unit Office. *Measurements*: SVL 460 mm; tail length 50 mm. *Pholidosis*: Ventrals 460; subcaudals 50; midbody scale rows 13; anal plate divided. *Remarks*: New record for Bhutan.

Family Viperidae

Ovophis monticola, Günther, 1864. BWS CKHQ-S4. Choetenkora, Trashiyangtse District, 1807 m. 1200 h. 7 June 2008. Most abundant species in Trashiyangtse and Mongar Districts, being reported not less than 21 times at Trashiyangtse alone. One specimen preserved. *Measurements*: SVL 510 mm; tail length 100 mm. *Pholidosis*: Ventrals 147; subcaudals 43; midbody scale rows 21; anal plate single. *Remarks*: New record for Bhutan.

Protobothrops jerdonii, Günther, 1875. BWS DPRO-S11. Barigang, Trashiyangtse District, 2143 m. 1450 h. 25 June 2008. Two individuals collected in same locality at a distance of ca. 30-minute walk from each other. First released and second retained in laboratory. *Measurements*: SVL 640 mm; tail length 112 mm. *Pholidosis*: Ventrals 177; subcaudals 51; midbody scale rows 21; anal plate single. *Remarks*: New record for Bhutan. A third specimen reported from Phanteng, Bumdeling, Trashiyangtse. 1130 h. 5 June 2008. After photography (BWS SPRO-S3) specimen released.

Acknowledgments.—I thank the management of Bumdeling Wildlife Sanctuary for initiating herpetological studies in the sanctuary, especially Karma Tenzing. The Bhutan Trust Fund for Environmental Conservation supported the survey. I thank our field survey partners from the management headquarters, Tashi Phuntsho, Pema Choden, Sonam Choidup, Jangchuk Dorji, Phurba Lhendup, Sangayla and staff from the field office of Serzhong, Mongar district, Karma Wangdi and

Namgay, and from Khoma, Lhuentse, Bal Krishna Koirala, Tshering Wangchuk and Tshewang Dorji. Ugyen Choephel, Forest Extension Officer, Sherimung, Mongar contributed photos of specimens, and the people of the Sanctuary area brought specimens and helped us catch live animals. Karthikeyan Vasudevan, Wildlife Institute of India, Dehradun needs a special mention for inviting me to the 2nd School in Herpetology. Thanks are also due to Amit Mitra, Sherubtse College, Kanglung, Trashigang. Eric N. Smith, Eduardo Müller, Gernot Vogel, and two anonymous reviewers helped improve this paper.

The fourth edition of the *Field Guide to Frogs of Western Australia* by Michael Tyler and Paul Doughty provides an excellent up-to-date (as of 2009) version of the guide first published more than 25 years ago by Tyler, Smith, and Johnstone. Updates to the previous version include concentrating information for a given species on a single page (or two), three helpful color maps in the inside back cover, and the inclusion of recently described species from the Kimberley (Doughty and Anstis 2007; Doughty and Roberts 2008; Doughty et al. 2009). To me, the book has all the hallmarks of an excellent guide regardless of your range of experience identifying frogs. This book is well produced and I would not hesitate to throw this book into my pack on my way out to go herping in Western Australia.

The organization of the book is smart and straightforward. First, as introduced in the third edition, the front inside cover contains four well-labeled diagrams highlighting major morphological features used in the guide for identification. In turn, and new to this edition, the inside of the back cover contains a map of Western Australia with close-up maps of the Kimberley and the Southwest. Following a short index, the book begins with a general overview of the four families of frogs found there (including Bufonidae for *Bufo* [*Rhinella*] *marinus*), followed by ten pages of basic information on frog biology and anatomy (including for tadpoles), and a page or so dealing with legislation related to frogs and regional comparisons within Western Australia. First introduced in the original edition of this book (accompanied by excellent line drawings by Linda Trueb and others), these concise descriptions of frog anatomy are well done and very accessible.

The book then proceeds alphabetically by genus. Each genus is provided a concise summary page, which is followed by

separate pages for each species in the genus. The genus-level summaries provide an informative entry into each genus with details on species diversity and phylogenetic relationships, morphological features, reproductive mode, and etymology (including my favorite explanation for *Litoria*: "the name may have been coined merely for the way it sounds").

Each species page has at least one color picture of the frog and a map showing point localities on a map of Western Australia. Collecting all of the information for each species all in one place (rather than a separate section of color plates) is one of the significant changes to the organization introduced in this edition. Scattered throughout the book are extra images that are either other color photographs of the species (sometimes in ventral view), line drawings depicting tadpoles or specific morphological features, and even a few sonograms. As a taxonomist, I appreciate that the authors used a color image of the holotype (and only) specimen of *Uperoleia marmorata* rather than excluding an image of it since there was no color image in life. The text for each species account contains sections providing a general morphological description and short summaries of its distribution, typical habitat, advertisement call, and breeding biology. The etymology for each species name is also provided. Many species also have a short section of remarks; these are among the most interesting bits in the book. Each species also has a few references for recommended reading, which are helpfully annotated so one knows whether the reference pertains to evolutionary relationships, reproduction, population biology, tadpoles, calls, etc.

The book concludes with other sections that are quite useful; several of these were added to the book in previous editions. First, it has a helpful collection of references that are more than sufficient for enabling the amateur and specialist alike to dive into the literature dealing with this frog fauna. There is also a two-page glossary section that nicely compliments the morphological descriptions in the beginning of the book and the labeled diagrams on the inside front cover. Following the glossary, the authors have included keys by region (Kimberley, Southwest, and the intervening Arid Zone) as well as "checklists of frogs for urban centres" organized by region. The latter is among my favorite parts of the book and was originally introduced in the second edition.

I found no problems with this book. There are only a few things to note for the more interested reader. The authors prefer to recognize *Cyclorana* as a genus rather than subgenus of *Litoria* (contra Frost et al. 2006). At the same time, the authors have opted to utilize the Limnodynastidae as a distinct family rather than as a subfamily within Myobatrachidae. Not included among the species in this book is *Litoria aurifera* (Anstis et al. 2010), which was, of course, described after the publication of this book.

If and when I ever write a field guide, I would happily follow the model set forth in this book. I have always had a fascination with Australian frogs and this only fueled my desire to visit and see some of these remarkable species. The authors make brief reference to "overseas froggers" in their preface, probably without considering that such a nice field guide may serve to attract a good number of overseas froggers to visit them in Western Australia, myself included.

Cane Toads and Other Rogue Species

Edited by Karl Weber. 2010. Participant Media, New York. Softcover. x + 243 pp. US $14.95. ISBN 978-1-58648-706-5.

FRED KRAUS
Bishop Museum, 1525 Bernice Street
Honolulu, Hawaii 96817, USA
e-mail: fkraus@hawaii.edu

One presumes that most herpetologists are by now familiar with, if not enraptured by, the 47-minute documentary "Cane

Toads: an Unnatural History," released in 1988 and directed by Mark Lewis. The film is famous for its hilarious depiction of the varied human responses to the invasion of *Rhinella* (formerly *Chaunus*, formerly *Bufo*, *nee Rana*) *marina* across northern Australia. The director has now followed up on his early success with the 90-minute sequel "Cane Toads: the Conquest" (2010). And, in the now-common trend of multimedia packaging, released

the same year is this companion book whose stated purpose is "to serve as a guide to the important, intriguing, and disturbing issue of rogue species." Alas, the book seems nothing but a quickly patched-together marketing ploy reeking of commercial cynicism.

The book has a four-page preface by the editor and is followed by 12 chapters treating (or at least touching on) varied aspects of the problem of invasive alien species. These are divided into three sections: "The Cane Toad Saga" (two chapters), "Rogue Species and the Future of the Planet" (seven chapters), and "What We Can Do" (three chapters). At the end is an appendix listing relevant books, websites, and organizations treating this issue so that the interested reader can explore the topic in greater depth. This is useful—and, indeed, necessary—because the book under consideration does such a poor job of meeting its stated goal. Despite the book's title, with the exception of the first chapter, there is nothing of interest herein for the average herpetologist.

Let's focus on the positive aspects of the book. As the reader familiar with the literature on this topic might expect, Dan Simberloff and James Carlton provide excellent summaries of their chosen (or assigned) topics. The former delivers a lucid and erudite case study of the invasives problem in Hawaii, one of the most invaded areas on earth. It provides a useful contrast to most of the other chapters in the book because it not only describes the ecological havoc caused by invasives in Hawaii but provides sufficient explantory detail of the underlying reasons for these impacts that the reader can understand why the damage occurs. This chapter serves as a compelling examination of a worst-case situation. Similarly, Carlton contributes a detailed explanation of how and why invasives are a problem in the oceans, giving a historical overview of the development and scale of the phenomenon, with development in this case being the addition through time of new dispersal vectors. He then gives several examples of the consequences of these invasions and finishes with a brief discussion of management options, including the rarely discussed need for early education (read: toward children) about the problem to instill more responsible attitudes toward biotic mixing.

In a very different vein, Nigel Turvey contributes a chapter replete with much new information on the history of the release of Cane Toads into Australia. The major events in the prerelease history are already available in the literature, but Turvey, using memos from the historical files of the Queensland Bureau of Sugar Experiment Stations and Queensland State Archives, fills in useful details and continues the history of political maneuvering past the release date in August, 1935. He provides a detailed case study of the contrasting political interests, human foibles, and mediocre judgement that continue to be replayed repeatedly around the world in the deliberate release of alien invasives. Turvey provides the best illustration of the profound banality of invasive-species release of which I am aware. It is also one of only two chapters with a specific focus on herps.

These are the chapters that shine. So does Chapter 9, which is a reprint of David Quammen's seminal 1998 essay "Planet of Weeds," originally published in *Harper's*. This essay is an eloquent exposition of the biotic extinction crisis and why it matters, with approximately 25–30% of the space devoted to discussing invasives, which was one of the first attempts to educate the general public about the problem. However, this chapter is clearly dated, and its inclusion contributes nothing particularly important toward a current understanding of the invasives problem or its solution.

Chapter 5, "The Fungus Amongus – Toad as Victim" by Chad Peeling, is a concise and well-written summary of the problem of chytridomycosis in amphibians (the second of two chapters with a herpetological focus). However, there are two caveats: (1) the title is a misnomer, since *R. marina* is not threatened by the chytrid fungus, and (2) the last paragraph asks how anyone could want to kill a toad (even if it is invasive), thereby missing the point that invasives are an issue of ecological and evolutionary context, not of the species per se. This is an odd remark to include in a book purporting to educate the public about the problem of invasive species.

The remainder of the book is a wash; indeed much of it is downright awful. I could bore the reader with the details, but it would take too long and is not particularly relevant for a review in a specifically herpetologically focused journal. To summarize, the book is a poorly edited, incoherent mishmash of chapters revolving around the general issue of invasive alien species. With the exception of the chapters mentioned above, most do not serve to educate; some are absolutely misleading. Nor is the situation improved by the attempt to coin yet another term ("rogue species") for a phenomenon already burdened with a history of competing descriptors. There is nothing of specifically herpetological interest in this book, with the exception that Turvey's chapter will be useful for the specialist in herpetological invasions. For lay readers wanting a general introduction to the problem of alien invasions, the works by Bright (1998), Devine (1998), Baskin (2003), and van Driesche and van Driesche (2004) are infinitely better written, coherent treatments, and I can recommend any of them as far more deserving of attention than the present title.

e-mail: frogs@umn.edu

Nebraska had gone over 65 years since Hudson's (1942) treatment of the state's amphibians and reptiles then, within weeks of one another, two new books on the topic were published. The two new books, *Amphibians and Reptiles of Nebraska* and *A Field Guide to the Amphibians and Reptiles of Nebraska*, despite their similar subject matter, are very different. The former is larger (18.4 × 15.4 cm and 400 pp. vs 12.1 × 19.1 cm and 161 pp.), with more in-depth coverage and referencing (4.5 pages per species with 970 references cited compared to two pages per species and no literature cited), and a heftier price tag (US $45.00 vs. $17.99). They also differ in the number of species treated; Fogell has 62, one more than Ballinger et al., as he treats Tiger Salamanders as two species (*Ambystoma tigrinum* and *A. mavortium*).

A Field Guide to the Amphibians and Reptiles of Nebraska (Fogell) is a nicely laid out and designed guide that has a short introduction and a two-page section on habitats. This is followed by a well done key for all amphibians and reptiles found in the state. The species names follow Crother (2008) with the exception of ratsnakes and foxsnakes for which *Scotophis* and *Mintonius* are used, as well as *Pantherophis*, without explanation. The accounts are standardized to two pages per species and include four text sections on one page—description, habitat, natural history, and distribution— and photos and a distribution map on the facing page. There are no citations in the text of the accounts. The maps show distribution by county, but do not provide information on the origin or age of the records. The last portion of the book includes short descriptions of species of possible occurrence, a glossary of terms, and a checklist of amphibians and reptiles of Nebraska.

This is a handy guide that fits nicely in one's pocket and is appropriate for persons with a general interest in the wildlife of Nebraska. It falls short for the serious student of herpetology, however, because of the lack of references and relatively cursory treatment of each species.

Amphibians and Reptiles of Nebraska (Ballinger et al.) is a major treatise on the herpetology of Nebraska. The three authors have over 60 combined years of experience with Nebraska reptiles and amphibians and over 30 collective years of work invested in this book. The book has extensive introductory chapters. "A Brief History of Herpetology in Nebraska," which covers works from prior to Hudson (1942) to the present, including a mention of the (then forthcoming) field guide by Fogell, gives a good overview of the research that has been carried out on the amphibians and reptiles of the state. The "Environments for Amphibians and Reptiles in Nebraska" chapter is over 20 pages long and covers the physiographic regions and vegetation types found in the state. There is also a section on conservation and a checklist to the species found in the state.

Ballinger et al. break up their key so the portion for each order is at the beginning of the sections for those species. The species accounts are laid out with sections on recognition, description, size, distribution, habitat, habits, variation, and remarks. There are multiple photos for each species showing different life stages, colorations, and habitats. The state maps show point localities with different dots that distinguish the records by age and smaller American maps show the broader distribution of each species. Unfortunately, the state maps all show gray speckling or smudging, probably due to low quality scans. The same problem is found in the line drawings used in the book.

The species accounts vary in length from three pages to over 10 pages. The authors mainly follow Crother (2008) for standard English and scientific names, except that they retain the use of the genera *Bufo* and *Rana*, explaining their rationale in the text. A single page of species of potential occurrence in Nebraska is presented. There is an extensive glossary and a 51-page Literature Cited section, with 970 references.

This book is a major treatise that will stand the test of time. Unfortunately, numerous typos, the use of informal terms like "herpetile," and the low quality maps and line drawings take off a little of the luster. It is too bad this book did not get the copyediting and design support that went into Fogell's *Field*

Guide. It would have been nice for the users of both books if the authors had collaborated to use one standard names list for Nebraska.

I will keep both of these books on my bookshelf. I will refer to Ballinger et al. when I need information about Nebraska amphibians and reptiles. When I am in the field in Nebraska I will have Fogell in my back pocket. It is too bad that these two projects could not have been merged, particularly considering the authors were all associated in some way with the University of Nebraska – Lincoln.

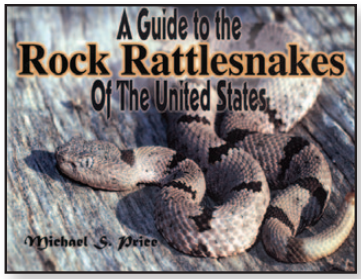
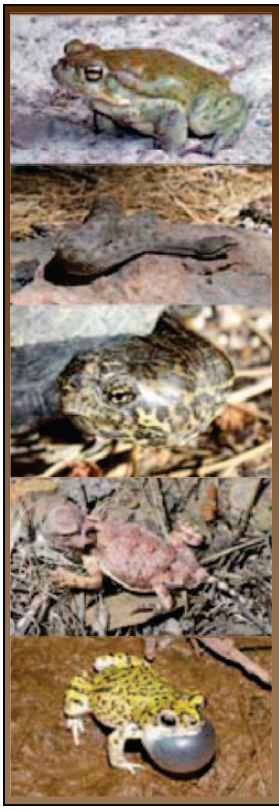
PUBLICATIONS RECEIVED

Herpetofauna del Valle de México: Diversidad y Conservación



By Aurelio Ramírez-Bautista, Uriel Hernández-Salinas, Uri Omar García-Vázquez, Adrian Leyte-Manrique, and Luis Canseco-Márquez. Prologue by Jerry D. Johnson. 2009. Universidad Autónoma del Estado de Hidalgo and CONABIO, Mexico, D.F. 213 pp. Softcover. US $40.00 (available from Bibliomania! www.herplitsales.com). ISBN 978-607-7607-18-2. [In Spanish]

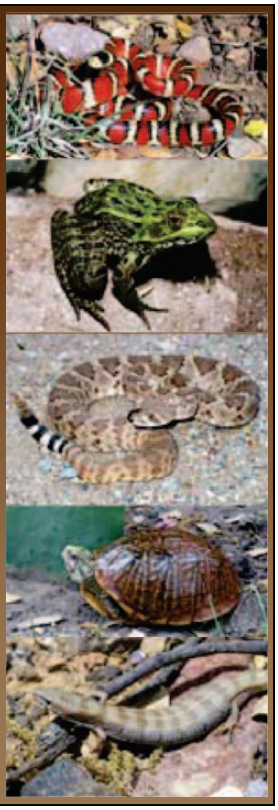


This volume joins a growing list of regional treatments of Mexico's wonderfully diverse herpetofauna, and like most of these other recent publications is the work of native Mexican herpetologists. This publishing wave reflects a movement to document Mexico's herpetological diversity in the face of growing conservation challenges. The Valley of Mexico, in particular, because of its long period of high-density human habitation, is a region of heavily compromised ecosystems, with some species already extirpated and others marginalized to vestiges of native habitats. Individual accounts for 69 species of amphibians and reptiles include descriptions, natural history, and distribution (with dot maps). Small color photographs are included for each species; where possible, specimens illustrated are from within the book's coverage area. Separate sections review distribution—from ecological and biogeographic perspectives—including levels of endemism, as well as diet, habits, and reproduction (noting the high percentage of viviparous squamates). The book concludes with a discussion of the conservation status of the region's herpetofauna as a group, as well as individual species that have disappeared already or are in imminent danger of regional extirpation. Herpetologists and conservation biologists with interests in Latin America will want to acquire this book.

A Guide to the Rock Rattlesnakes of the United States

By Michael S. Price. Foreword by Travis J. LaDuc. 2009. ECO Herpetological Publishing, Rodeo, New Mexico (www.ecouniverse.com). 160 pp. Softcover. US $24.95. ISBN 978-0-9788979-9-4.

This book is a photographic atlas documenting the extensive phenotypic variation in *Crotalus lepidus* within the United States. This species has been Michael Price's passion for a number of years, and he has traveled widely throughout the American Southwest to observe and record Rock Rattlesnakes from the mountains of southeastern Arizona and adjacent New Mexico eastward into the desert and near-desert environments of West Texas. Within this region, *C. lepidus* occupies a broad range of elevations and habitats (nearly always rocky), and populations of snakes display differences in adult size and color pattern. The geographic range and morphological variation is even more extensive south of the U.S.–Mexico border and will be the subject of a future book by Price. The present volume contains hundreds of high-quality color photographs depicting 240 individual snakes from 52 discrete localities (many also illustrated by color photographs). Price recognizes five "phenotypes"—but in reality these are not diagnosed morphologically but simply allocated to ecoregions (e.g., "Edwards Plateau / Eastern Phenotype," etc.). Although this book would have benefited from a stronger editorial presence, its value lies in the voluminous compilation of images that record the variation in this diverse group of snakes.



American Museum of Natural History's
Southwestern Research Station
Field Herpetology of the Southwest
24 July – 3 August, 2011

During this 10-day course, participants will gain knowledge on the outstanding biodiversity of amphibians and reptiles found in a wide diversity of habitats throughout southeastern Arizona and parts of southwestern New Mexico.

Participants will obtain hands-on experience in amphibian and reptile identification, collecting and marking techniques, and data documentation. The course also will cover specimen preparation of a full museum voucher specimen, including tissue vouchers and photographs.

For more information about the course contact Dawn Wilson
Ph: 520-558-2396; Email: dwilson@amnh.org

INFORMATION FOR CONTRIBUTORS

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (for information, please refer to: http://www.ssarherps.org/pages/JHinstr.php). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

REPRINTS AND PAGE PROOFS

Reprints of notes or articles published in ***HR*** may be ordered through EZReprints (EzReprint@odysseypress.com), an online reprint ordering system. Authors will receive email notification as the issue goes to press. Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not sent for natural history notes or geographic distribution notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication. Corresponding authors who are current members of SSAR will automatically receive free, screen-resolution pdf files of their articles or notes.

ADVERTISING

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices.

All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes.

POSTMASTER: Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR PUBLICATIONS

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available for purchase from the SSAR Bookstore (http://www.ssarbooks.com/). Use the prices below to order back issues.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:

http://www.ssarherps.org/pages/membership.php

Future Annual Meetings

2011 — Minneapolis, Minnesota, 6–11 July (with ASIH, HL)
2012 — Vancouver, British Columbia, 8–14 August (7th World Congress; also SSAR, HL, and ASIH)
2013 — Albuquerque, New Mexico, dates TBA (with ASIH, HL)

About Our Cover: *Drymarchon couperi*

Among the largest of colubrid snakes—reaching adult lengths of 1.6–2.95 m—are members of the genus *Drymarchon*, the indigo snakes. Collectively, their range spans some 55° degrees of latitude, extending from the southeastern United States to northern Argentina. Herpetologists have long considered *Drymarchon* as monotypic (*D. corais*) with up to eight subspecies. Currently, four species are recognized based on morphology and color patterns (Wüster et al. 2001. Herpetological Journal 11:157–165).

In sandy pineland habitats in Georgia/Florida, the Eastern Indigo Snake (*Drymarchon couperi*) has an intimate association with the Gopher Tortoise (*Gopherus polyphemus*), using the long, deep burrows of this turtle for winter dens, foraging, and nesting. Many landowners and outdoorsman revere Eastern Indigos because of their docile temperament and beauty. The colloquialisms "blue gopher" and "gopher snake" capture the species' predilection for tortoise burrows and the violet iridescence of the dorsal scales in sunlight. This North American icon was federally listed in 1978 as "Threatened" due to population declines attributable to habitat loss and overcollection for the pet trade. The practice of introducing gasoline into Gopher Tortoise burrows to evict Eastern Diamondback Rattlesnakes (*Crotalus adamanteus*) may still be employed by some snake hunters; doing so has been shown to be lethal to any Indigo Snake residing in a "gassed" burrow; currently, three rattlesnake roundups are held annually (two in Georgia, one in Alabama) at sites within or near the range of *D. couperi*.

Like other members of the genus, *D. couperi* are diurnal, active foragers that feed on a wide array of vertebrates, particularly snakes, including venomous species. Formidable and indiscriminate predators, they prowl wetland margins and probe their heads into burrows when searching for prey; snake prey are typically seized by the head, chewed until immobilized, then swallowed head-first. Interestingly, a number of the forms of *Drymarchon* commonly consume small turtles (H. W. Greene, Cornell University, pers. comm.). (And, somewhat ironically, Eastern Indigos frequently eat hatchling Gopher Tortoises [Stevenson et al 2010. Southeastern Naturalist 9:1–18]). Mark-recapture field studies in southern Georgia have documented that adult Eastern Indigo Snakes exhibit male-biased sexual size dimorphism, require 3–4 years to reach sexual maturity, display winter den site fidelity by returning to the same tortoise colonies in successive years, and commonly live to be 8–12 years of age on vast protected landscapes (Stevenson et al. 2009. Herpetological Conservation and Biology 4:30–42).

Our cover features a female *Drymarchon couperi* found basking in January 2009 near a Gopher Tortoise burrow in Longleaf Pine-Wiregrass sandhill habitat along the Canoochee River, Georgia. **Dirk J. Stevenson** recorded this image with a Sony MVC–CD500, equipped with a Zeiss macro lens at f22, ISO 400, 1/30 sec exposure, and auto fill flash. Stevenson is Director of Inventory and Monitoring with The Orianne Society (www.projectorianne.org), a nonprofit organization dedicated to the conservation of imperiled amphibians and reptiles. Elsewhere in this issue (pp. 437–442), Stevenson and colleagues investigate the effectiveness of using wildlife detector dogs to locate Eastern Indigo Snakes.

SSAR BUSINESS

2010 Annual Meeting, Providence, Rhode Island

The 53rd Annual Meeting of SSAR took place from 7–12 July 2010 at the Weston Providence Hotel, Providence, Rhode Island, USA. The Organizing Societies were Society for the Study of Amphibians and Reptiles (in conjunction with the International Society for the History and Bibliography of Herpetology), American Elasmobranch Society (celebrating its 26th annual meeting), American Society of Ichthyologists and Herpetologists (celebrating its 90th annual meeting), and The Herpetologists' League (celebrating its 68th annual meeting). The meeting was hosted by University of Rhode Island, Brown University, and University of Connecticut. The local hosts were Jacki Webb (Chair), Beth Brainerd, Eric Shultz, Kurt Schwenk, Cheryl Wilga, and Brad Wetherbee. Once again, the local hosts were ably assisted by the staff of KState University Division of Continuing Education and by many student volunteers (from University of Rhode Island, Brown University, and University of Connecticut).

There were 1031 herpetologists and ichthyologists from around the world at the 2010 JMIH. This number was down slightly compared with that in the previous year (1170). Attendees hailed from 25 different countries (e.g., Argentina, Australia, Austria, Belgium, Canada, Germany, Italy, Korea, Malawi, Malaysia, The Netherlands, Poland, New Zealand, Saudi Arabia, United Kingdom, United States, Venezuela). Approximately 45% of attendees were students, and around 520 papers and 260 posters were presented. Twenty-eight exhibit booths were staffed. Seven symposia, including one sponsored by SSAR and ASIH "Head-Starting Turtles—Learning from Experience" (Fig. 1), and three student workshops were scheduled. A workshop on grant writing was organized by Dawn Wilson and other members of the SSAR Graduate Student Participation Committee. The Henri Seibert Competition attracted 28 students in four categories this year.

The Annual Meeting began officially at 0900 h on Thursday, July 8th with welcomes from the Chair of the Local Host Committee, Jaqueline Webb (University of Rhode Island) and Nancy Fey-Yensen (Interim Dean, College of the Environment and Life Sciences, University of Rhode Island). Kentwood Wells, this year's ASIH speaker, gave a presentation on "The Social Behavior of Anuran Amphibians: What Have We Learned in the Last 35 years?" This was followed by the presentation of three ASIH Awards (Gibbs, Fitch, and Johnson awards) to John Lundberg, Tom Schoener, and Joe Nelson, respectively. The first winner of the new SSAR/ASIH/HL Meritorious Teaching Award in Herpetology, Whitfield Gibbons, was then announced by President Crother. ASIH Past-President John Lundberg spoke on "Authentic American Cryptoichthyology," followed by The Herpetologists' League's distinguished herpetologist for 2010, Indraneil Das from University Malaysia, Sarawak, who spoke on "Perceptions, Use and Conservation of Amphibians by Indigenous People Worldwide." The AES speaker, Gregor Cailliett gave an address on "Ageing, Age Validation, Growth and Aging: The Life Histories of Chondrichthyan and Deep-Sea Fishes" and the Plenary Session was closed by Jacqueline Webb.

Social and Professional Events

Robert Espinoza (California State University, Northridge) was this year's President's Travelogue speaker and gave his presentation ("The Herpetofauna of South America's Southern Cone: New Discoveries from the Andean Peaks to the Peruvian Steppe") on July 7th (Fig. 2). He spoke about the extremes of temperature and water availability and the great diversity of reptiles and amphibians in this area. Bobby acknowledged Richard Etheridge who introduced him to Argentina and Argen-

FIG. 1. Participants in this year's highly successful symposium, "Head-starting Turtles. Learning from Experience," organized by Russell Burke and co-sponsored by SSAR and ASIH. Standing (from left to right): Willem Roosenburg, Roger Wood, Slawomir Mitrus, Tom Herman, unknown, Tom French, David Taylor, Lisa Hazard, Ken Nagy, Russ Burke, Tracey Tuberville, Brian Windmiller, Stephanie Koch, Charles Innis, Matt Hinderliter, Maria Wojakowski, Peter Warny, unknown. Seated (from left to right): Thane Wibbels, unknown, unknown, unknown, Kurt Buhlmann. (Photo M. Preest)

FIG. 2. Beck Wehrle, Denita Weeks and Navasha Singh (L to R) students of this year's President's Travelogue Speaker Robert Espinoza (second from right). Denita was the 2010 Seibert Award winner in the Morphology/Physiology section. (Photo M. Preest)

tinian herpetofauna, as well as the many friends and contacts he and his students have developed over the years. Every year SSAR manages to find a great Travelogue speaker and this year was no exception.

On the evening of July 8th, SSAR joined with HL to host another very successful reception for student members of both Societies and invited professionals (Fig. 3). The Joint Meeting Reception was held immediately after the Student Reception at the Roger Williams Park Zoo. After a long wait for buses by most (Fig. 4a) and a detour to a casino for some, good barbeque and interesting exhibits were enjoyed by those who finally made it (Fig. 4b).

In addition to the planned gatherings, many meeting attendees felt the need for some "field work" and explored local dining establishments and pubs (Fig. 5).

Twenty two students attended a pizza lunch and student workshop on grant writing organized by the Student Participation Committee on July 9th. The workshop included a panel of professional herpetologists (Robert Espinoza, Al Savitzky, Rafael de Sá, Henry Mushinsky, Karen Warkentin, and Dawn Wilson) from a variety of types of institutions offering valuable advice, including how to set a proposal in a broader context, how important it is to stress the relevance and novelty of the proposed research, and how to include preliminary data. Al and Rafael spoke of their work at NSF, as well as their own experiences writing grant proposals.

The SSAR/HL Live Auction occurred on July 11th and raised $3759.50 to support graduate student travel ($1706 of this was the result of items from the Roger Conant library). Frank Burbrink served as auctioneer and was assisted by Greg Watkins-Colwell, Samantha Wisniewski (who has helped with several of the past few auctions), Ben Jellen, Phillip Skipwith, Heather Heinz, and Taryn Cazzolli among others (Fig. 6). Greg also served as onsite coordinator before the meeting began.

Matt Venesky and Cari Hickerson (co-Chairs, Student Travel Award Committee) again worked hard to pull together a successful Silent Auction. $727 was raised to support the SSAR Student Travel Fund. Thanks to this year's winners of SSAR Student Travel Awards who helped staff the exhibit desk.

A rather hastily organized evening session dealing with the ichthyological and herpetological implications of the oil spill in the Gulf of Mexico was held on July 10th. Close to standing-room-only in a large ballroom was an indication of the level of interest in this topic.

The Joint Meeting Banquet was held on the last evening of the meeting, with Lynn Parenti serving as Master of Ceremonies. SSAR was represented at the head table by Brian Crother (President), Kirsten Nicholson (Treasurer), Marion Preest (Secretary), and SSAR member Mary White. Five past-Presidents of SSAR were in attendance. At the end of the Banquet, an invitation was issued to attend the 2011 JMIH in Minneapolis, Minnesota, July 6–11. Pat Gregory (Chair, Local Committee) invited all the world's herpetologists as well as our ichthyological colleagues from ASIH and AES to the 2012 JMIH/World Congress of Herpetology meeting in Vancouver (August 8–14). A meeting website is already up and a call by WCH for symposia has been issued.

BOARD MEETING AND BUSINESS MEETING SUMMARIES

Society President Brian Crother called the Board Meeting to order at 0803 h on July 7th, 2010 in the Westin Providence Hotel, Providence, Rhode Island. In attendance were the following members of the Board of Directors, Editors, and Committee Chairs: Kraig Adler (Editor, *Contributions in Herpetology*), Aaron Bauer (Editor, *Facsimile Reprints in Herpetology*), Brian Crother (President; SSAR Rep MMPC; Chair, Standard English and Scientific Names Committee), David Cundall (Board Member, Reg. 2012), Kevin de Queiroz (Board Member, Reg. 2012),

FIG. 3. Jay Savage, Villanova student Alicia Kennedy, Mary White, and Treasurer Kirsten Nicholson enjoying the SSAR Student Reception. (Photo M. Preest)

Fig. 4a (top). A long wait for buses to the JMIH Picnic at the Roger Williams Park Zoo; 4b (lower) but worth it when we got there. (Photo M. Preest)

Tiffany Doan (Board Member, Reg. 2010), Pat Gregory (Board Member, non-US 2012), Roy McDiarmid (Past-President), Joe Mendelson, III (President-Elect), John Moriarty (Editor, *Herpetological Circulars*), Erin Muths (co-Editor, *Journal of Herpetology*), Kirsten Nicholson (Treasurer), Pat Owen (Chair, Seibert Award Committee), Ann Paterson (Board Member, Reg. 2012), Marion Preest (Secretary), Stephen Richter (Board Member, Cons. 2010), Betsie Rothermel (Chair, Conservation Committee), Al Savitzky (SSAR Rep to AIBS and BioOne), Greg Watkins-Colwell (Chair, Nominations Committee; Chair, SSAR/HL

Fig. 5. Matthew Morrill, Alex Pyron, Greg Watkins-Colwell, Meredith Mahoney, and Frank Burbrink (L to R) enjoying the "best beer in Rhode Island" at one of the many local pubs. (Photo M. Preest)

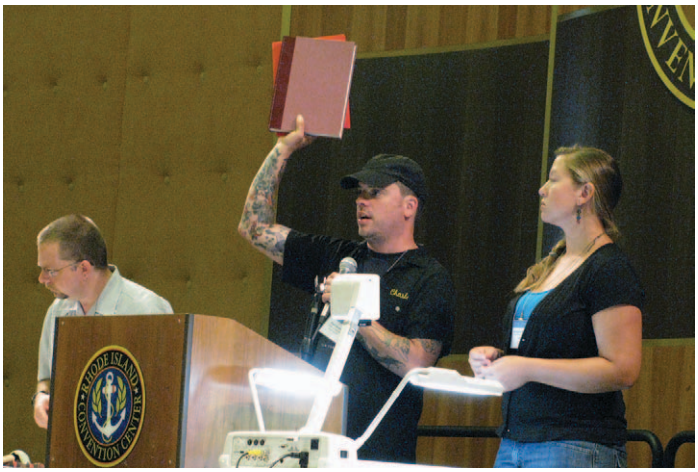

Fig. 6. Greg Watkins-Colwell (far left, the new Chair of the Live Auction Committee) was energetically and persuasively assisted by Frank Burbrink and Samantha Wisniewski at the auction. (Photo M. Mahoney)

Live Auction Committee), and Dawn Wilson (Chair, Student Participation Committee). Additional society members present included Robin Andrews and Henry Mushinsky. Minutes of the 2009 Board of Directors Meeting (Portland, Oregon) were approved.

Annual reports for 2009/2010 were submitted by all Officers, Editors, and Committee Chairs. President Brian Crother reported that SSAR became involved as a Festival Partner with the USA Science & Engineering Festival to be held in Washington D.C. in October, 2010. SSAR will have a booth at the festival and Joe Mendelson, III is in charge of our participation in this national event (see event report elsewhere in this issue). The editor of the *Journal of Herpetology*, Matthew Parris, unexpectedly stepped down in early 2010, but Brian noted that the Society was fortunate to find new editors, Gad Perry and Erin Muths, fairly quickly. It is anticipated that a two-editor system will improve our manuscript turnaround time. Welcome aboard to Gad and Erin and many thanks to them for stepping up to take this key position. Thanks also to Geoff Smith, a previous editor, for stepping in and helping smooth the transition.

President Crother reported writing or signing a number of letters pertaining to SSAR business over the past year, including various letters submitted by the Conservation Committee, letters of congratulations to national and international herpetological societies acknowledging significant landmarks, and letters of thanks to Maureen Donnelly (President's Travelogue speaker, 2009) and to the participants in the 2009 JMIH SSAR Student Workshop.

Treasurer Kirsten Nicholson reported that, overall, the finances of SSAR are fairly sound and doing well. The approved 2009 budget was balanced and the Society came in under budget by around $7,000. Costs for production of our journals are increasing and we may need to review the manner in which we produce them and develop our presence online. Membership management fees assessed by Allen Press have been much higher than anticipated. Membership management was taken over by Breck Barthlomew in October 2009 and our costs are expected to be half of those charged by Allen Press. Our membership is holding steady overall. Institutional subscriptions have fallen, however individual memberships have increased. Although growth in membership levels would be better, holding steady is very good, given the decrease in memberships experienced by most societies. It is not clear if institutions are dropping memberships to remove duplication of effort or to reduce costs by having a BioOne (or other similar) contract which would provide *Journal of Herpetology* to them without having a subscription directly with us. This would explain the huge increase in royalties we are enjoying, which is expected to continue to rise. A comment was made that SSAR needs to offer an electronic-only membership option. The Society's investments made a substantial rebound during 2009. Total market value increased

28% (from $383,743 to $496,004). Kirsten had considered a review and possible revamp of our investment portfolio, but considers it prudent to stay the course at present until conditions change.

Secretary Marion Preest provided Officers, Editors, and Committee Chairs with minutes of the 2009 Board Meeting and summarized the 2009 Annual Meeting for publication in *Herpetological Review*. She keeps track of changes in personnel and regularly updates SSAR letterhead, informs the Editors of *Journal of Herpetology* and *Herpetological Review* of these changes and provides various updates to Raul Diaz (webmaster). She routinely writes letters to student winners of various awards (e.g., Kennedy, GIH, etc.) and prepares announcements for publication in *Herpetological Review*.

The Secretary compiled the 2010 Annual Report and prepared agendas for the Board and Business Meetings for the 2010 JMIH. She was again involved in helping to organize a reception for student members of SSAR and The Herpetologists' League to be held at the JMIH.

A major task in 2009 was to contact all members who are entitled to *CAAR* as part of their membership and inform them of changes to the publication schedule and how we would deal with this. She corresponded with the Board regarding various issues that needed a vote, e.g., a proposal to accept a donation to fund increased use of color photos in *Herpetological Review* and *Journal of Herpetology*, a letter regarding the Natural Science Collections Alliance, a change in editorship for *Journal of Herpetology*, approval of JMIH symposia, etc. Marion framed the Special Libraries Association certificate that SSAR received last year and sent it to Matt Parris. Gad Perry has it currently and it will be passed on to new Editors as necessary. As an *ex officio* member of the Nominations Committee, the Secretary helped to identify and contact potential candidates for the four positions we need to fill in 2010.

Breck Bartholomew reported that total income from the Publications Office in 2009 was $64,651.90.

Editor of *Catalogue of American Amphibians and Reptiles* Andy Price, reported that accounts 861–880 (2 salamanders, 7 frogs, 2 turtles, 7 lizards, 2 snakes, 113 total pages) were published in January 2010 and mailed to subscribers in March. Every account in this issue had at least one color illustration. Andy has 12 accounts on hand in various stages of completeness but is unlikely to have an issue ready by the end of 2010. The frog section editorship is vacant, and the snake editorship will change soon. Andy considers the following as minimal qualifications for a section editor: 1) the ability to recruit authors for accounts, 2) a comprehensive knowledge of the literature not limited to systematics and taxonomy, 3) the ability to pay attention to detail including spelling, syntax, and punctuation, and 4) the ability to check bibliographic entries for accuracy and completeness, and to cross-match these with text citations. If anyone knows of a suitable candidate for either position, please contact Editor Price.

Editor of *Contributions to Herpetology* Kraig Adler reported that "Biology of the Reptilia, Volume 22, Comprehensive Literature of the Reptilia," by Ernest A. Liner was published in March 2010. "Snakes of Honduras" by James McCranie will be published in 2010/2011. A $5,000 donation has been received to support publication.

A "Guide to the Snakes of the Philippines" by Rafe Brown, Alan Leviton, Maren Gaulke, and Arvin Diesmos, "Field Guide to Amphibians and Reptiles of the West Indies" by S. Blair Hedges, and "Lizards of Southern Africa," edited by William R. Branch and Aaron Bauer are planned beyond 2010.

Editor of *Facsimile Reprints in Herpetology* Aaron Bauer reported that no new titles were published in the past year. "Gray's Catalogue of the Specimens of Amphibians and Reptiles in the Collection of the British Museum" is planned for late 2010. Duméril and Bibron's "Erpétologie Générale ou Histoire Naturelle Complète des Reptiles" (1834–1854) is planned for publication in late 2011. This is one of the most important of all herpetological works and a truly comprehensive summary of all amphibian and reptiles species known at the time. The original was nine volumes in 10, totaling over 7000 pages with a separate Atlas of 120 plates. The facsimile will be produced in the same format, with colored plates in the Atlas and black and white versions of the plates also bound into the volumes with which they are associated. The cost of the original work today is in the neighborhood of $20,000. Funding permitting, it is hoped that SSAR will be able to sell the full set at less than $300.

Editor of *Herpetological Circulars* John Moriarty reported that "Reptile Dealers and their Price Lists" was withdrawn by the authors. *Herpetological Circulars* 39 ("A Guide to Tissue Collection, Preservation, and Management for Reptiles and Amphibians" is in preparation and publication is planned for late 2010. Because *Herpetological Circulars* are print on demand, reprint costs are now a factor in the budget for this publication.

Joe Mitchell (Editor) reported that *Herpetological Conservation*, Volume 3 ("Urban Herpetology") has sold well. It was nominated for an award from The Wildlife Society.

Herpetological Review continues to operate smoothly according to Editor Robert Hansen. Volume 40 was slightly smaller (reflecting budget constraints) and the same is likely to be true for Volume 41. Personnel changes include Margaret Gunzberger, Marc Hayes, and Andy Holycross stepping down and Peter Lindeman, Jesse Brunner, Kerry Griffis-Kyle, Michael Benard, Jackson Shedd, and J.D. Wilson joining the staff.

As of late 2009, issues of *Herpetological Review* from 2007 onwards are available to SSAR members as PDF downloads from the ZenScientist website. The Board discussed electronic publishing of *Herpetological Review* again this year. It was felt unanimously that electronic publishing is essential for the future of this publication and for the Society, and must therefore happen sooner rather than later. The issue of indexing of past issues must be resolved. Increased use of color was also considered again. Hansen has obtained reduced color charges from Allen Press and has accessed the Beauvais Fund in support of color printing (evident in the first issue of 2010).

Matthew Parris stepped down as Editor of *Journal of Herpetology* in early 2010 and was replaced by Gad Perry and Erin Muths. Geoff Smith is serving as "Interim Editor" and processing all manuscripts submitted before 2010. There have also been some changes in the roster of Associate Editors. The current list partially reflects an interest in expanding the global reach of *Journal of Herpetology*.

Submission rates were markedly reduced in 2009 (down ~ 30%), but submissions to date for 2010 are higher than for comparable periods in 2009 and 2008. Rejection rate continues at around 60% and there is approximately a nine-month wait between acceptance and publication (down somewhat relative to the previous year). The change in journal leadership has resulted in longer than desired handling times for some manuscripts, however, the Editors have reduced the backlog drastically thanks to the work of Geoff Smith. They are hopeful that the entire process will be back to desired levels by the end of 2010.

The co-editors brought five issues to the attention of the Board.

1) Journal Format — There was discussion of a recommendation to convert *Journal of Herpetology* to an 8.5" x 11" trim size at the 2009 Board Meeting. Editors Muths and Perry are still waiting to receive relevant numbers and mockups from Allen Press. Once they receive them, this issue will be submitted to the Board for an electronic vote.
2) Electronic Publishing — They recommended that the Board continue consideration of electronic publishing of *Journal of Herpetology* with the expectation that this would happen by 2012. It is not obvious whether this would affect SSAR membership levels. The Editors are awaiting information from Allen Press on the financial implications of electronic publishing.
3) Rewarding Associate Editors — There was discussion of a suggestion that Associate Editors receive free membership as a token of appreciation for their efforts. There was also discussion of the fact that some Associate Editors are not members of SSAR. The sense of the Board was that membership should be an expectation, but not a requirement. The President could contact new Associate Editors

who are not members of the Society, and encourage them to join. Editor Muths will write a draft of this letter and send it to President Crother and President-Elect Mendelson.

4) Editorial Board — The Editors questioned the role of the Editorial Board. Their function is to serve as guaranteed reviewers and the Board recommended that they be used more in this manner.
5) Page Charges — Whether a strong policy regarding page charges should be developed and enforced was again discussed. In 2009, the Board asked Editor Parris to develop such a policy. As this was not done, the Board asked the current editors to develop a policy for its consideration. This policy needs to address the issue of charges for both black and white and color pages.

When *Journal of Herpetology* is published electronically, increased use of color plates will be possible. Some reservations were expressed about having two versions of each issue (electronic and hard copies). One version (likely the hard copy) will need to be designated as the official version.

Three new members were added to the Conservation Committee this past year. The Committee took action on a number of items: a) they supported a petition to list western U.S. populations of the Northern Leopard Frog as threatened, b) they sent a letter to U.S. Fish and Wildlife Service (USFWS) requesting re-initiation of an incidental take permit for a wind farm project which may affect the federally threatened Puerto Rican crested toad and contacted Puerto Rican authorities encouraging greater protection of remaining habitat for this species, c) they submitted a letter to USFWS urging federal listing and habitat designation for the coquí llanero, d) they expressed support for proactive strategies for curbing introduction and spread of invasive species (e.g., large constrictors) and stated their position that removal of these organisms (e.g., through controlled hunting) is unlikely to be effective, e) they wrote to the Florida Fish and Wildlife Conservation Commission (FFWCC) to encourage adoption of new rules regarding take and possession of native freshwater turtles.

Actions of the Committee contributed to several positive developments in the past year. For example, the local Planning Board in Puerto Rico temporarily suspended their decision to approve a wind farm project and allowed time for reconsideration, and the FFWCC approved new rules that prohibit commercial harvest and impose strict daily limits on the take of wild turtles in Florida. President Crother remarked on what 10 people can accomplish and congratulated the Committee on its efforts.

Betsie expressed some reservations about a small Committee representing the views of the entire Society and there was some discussion of soliciting greater input from the membership (e.g., via email, a web forum, or an online survey). The view of the Board was that this could be unwieldy and slow down the process and commended the Committee on its activities.

Joe Beatty (Chair, Dean Metter Award Committee) received 24 proposals this year and it was decided to choose two winners. They are: Matthew Niemiller (University of Tennessee, Knoxville) who is working on the maintenance of distinct cave and surface forms in the salamander genus *Gyrinophilus*, and Michael Reichert (University of Missouri, Columbia) who is studying acoustic communication in *Hyla versicolor*. Michael is the first student from University of Missouri in Columbia (which is where Dean Metter was a long time faculty member) to win this award. The Board encouraged Joe to advertise the Award via the SSAR website and an emailing to student members of the Society.

Erik Wild and Josh Kapfer (co-chairs, Grants-in-Herpetology Committee) received 55 proposals in 2010. Applications were sent from 19 states in the US and nine countries (including the U.S.). Most applications were received in the "Field Research" category. The winners each receive $500 and they are:

Conservation: James C. Cureton II, Sam Houston State University
Field Research: Karla Moeller, Arizona State University
Laboratory Research: Tara A. Pelletier, Louisiana State University
Travel: Lindsey Noel Swierk, Penn. State University
International: Paulo Fernando Guedes Pereira Montenegro, Universidade Federal da Paraíba (Brazil)

Eric is stepping down as co-chair of the committee.

The 18th annual Seibert Awards Competition was run at the 52nd Annual Meeting of SSAR in Portland, Oregon. There were 35 eligible presentations. The Seibert Award winners for 2009 were: **Systematics/Evolution**: *Jamie Oaks*, University of Kansas, "Objective partition choice and the phylogenetic systematics and biogeography of the true crocodiles." **Ecology**: *John Wilson*, Brian Todd, and Christopher Winne, University of Georgia, Savannah River Ecology Lab, Virginia Polytechnic Institute and State University, "Trap-happiness, temporary emigration and other factors affecting detectability and population estimation in aquatic snakes." **Physiology/Morphology**: *Victoria Arch*, T. Ulmar Grafe, Marcos Gridi-Papp, and Peter Narins, University of California, Los Angeles, University Brunei Darussalam, "An Old World frog communicates in pure ultrasound." **Conservation**: *Kristine Kaiser*, Menemsha Alloush, Robin Jones, Susanne Marczak, Katherine Marineau, Mark Oliva, and Peter Narins, University of California, Los Angeles, "When sounds collide: effects of anthropogenic noise on frog calling behavior."

Honorable mentions were: **Ecology**: *Javan Bauder*, Holly Akenson, and Charles Peterson, Idaho State University, University of Idaho, "Over the hills and far away: movements of prairie rattlesnakes across a mountainous landscape in a designated wilderness." **Conservation**: *Anna Savage*, Cornell University, "Experimental infection with *Batrachochytrium dendrobatidis* demonstrates genetic resistance to chytridiomycosis in *Lithobates yavapiensis*."

All winners received a check for US $200 from SSAR and a book from University of California Press, the latter compliments of UCP Editor Chuck Crumly.

The Herpetological Education Committee website has been active for a year and members respond to various enquiries submitted to the Herp Hotline. Members have also been active in developing and encouraging educational activities in herpetology. The Committee received support in 2009 from SSAR, HL, and ASIH for a proposal for a Meritorious Teaching Award in Herpetology. Ten nominations were received and considered by a Committee consisting of professional and student members of the three participating societies.

Lynnette Sievert (Chair, Kennedy Award Committee) announced that the winning paper for 2009 is by Ermin Schadich, "Skin peptide activities against opportunistic bacterial pathogens of the African clawed frog (*Xenopus laevis*) and three *Litoria* frogs. *Journal of Herpetology* 43:173–183." Ermin will receive a check for $200 or $400 equivalent in SSAR publications.

The Meeting Management and Planning Committee (MMPC) met in Providence in March 2010 to develop a meeting schedule and review conference facilities. President Crother and President-Elect Mendelson, who will replace Brian on the MMPC, attended the meeting as SSAR representatives. Almost 800 presentations (papers and posters) will be made at the 2010 meeting. Future meetings are to be held as follows:

- Minneapolis (2011)
- Vancouver (2012; with the WCH)
- Albuquerque (2013)

A survey conducted by the MMPC last year confirmed that many members thought the meetings were too expensive. Consequently, the MMPC invited two meeting management companies (KState and Experient, Inc.) to submit competitive bids for the 2013 meeting in Albuquerque. Experient's bids failed twice to provide costs for a number of services (e.g., web design and maintenance for registration and abstract submission, meeting announcement postcards, program book, abstract CD and book, reimbursements for MMPC, etc.). This process had two outcomes. It opened the eyes of the MMPC to the quality of service we receive from KState and it made KState aware of how serious the MMPC is in reducing meeting costs. Subsequently, KState joined with

another meeting management company to reduce costs of site selection and hotel negotiations (e.g., reduced or eliminated room rental fees, eliminated the need for a food and beverage minimum required for free or reduced room rental fees, eliminated fees associated with not filling a certain percentage of our room block).

The MMPC presented a proposal to make the MMPC a JMIH, rather than an ASIH, Committee and a proposal to reduce expenses at future meetings. These proposals were discussed by the Board later under New Business.

The MMPC also considered, but took no action on, the issue of reduced registration rates for accompanying and retired persons. Lightning round talks and the future and format of the banquet were discussed. A competition for a JMIH logo, separate from the individual society logos and the local meeting logo is being run. It will reflect combined interests in cartilagenous and bony fishes, amphibians, and reptiles and act as a banner for the JMIH meeting websites.

Five symposia were approved for the 2011 meetings.

ASIH — Turtle Ecology on the Upper Mississippi River System, Then and Now: A Zeitschrift in Honor of the Career in Turtle Biology of Dr. John M. Legler

ASIH — Drawing Lines in the Sand: Comparative Phylogeography of the Gulf-Atlantic Coastal Plain

ASIH — Ranaviruses: An Emerging Threat to Ectothermic Vertebrates

SSAR — Assisted Reproductive Technologies and Genetic Resource Banking: Tools for Conserving Declining Amphibians

AES — Elasmobranch Telemetry

Greg Watkins-Colwell reported that no elections were held in 2009. In 2010, SSAR needs to elect a President-Elect, Secretary, Treasurer, and three Board Members (Regular, Conservation, Regional Herpetological Societies). The committee plans to submit suggestions to the Board on how to define (or re-define) some of the specialty Board positions such as "Regional Herpetological Societies."

Stu Nielsen presented resolutions at the SSAR Business Meeting in Portland in 2009. Stu stepped down as Resolutions Chair and was replaced by Rob Denton.

The 6th Edition of the Scientific and Standard English Names List was published two years ago and the web version is close to posting. Brian Crother, Chair of the Standard English and Scientific Names Committee, thanked Raul Diaz for his help in getting this accomplished. Kevin de Queiroz donated many photographs and has worked closely with Raul on the website version.

Dawn Wilson reported that SSAR held a pizza lunch and workshop ("How to Get a Job After Graduation: Advice from Experts") for students at the 2009 JMIH. A workshop will be offered in 2010 on a topic decided on the basis of an exit survey given to students at the 2009 workshop. For improvements, students suggested more specific workshops, longer workshops, holding different workshops for undergraduates and graduates, and not overlapping the workshop with other meeting activities. Dawn will contact students attending the 2010 JMIH and ask for ideas for future workshops. Roy McDiarmid suggested a workshop focusing on nomenclature.

New co-chairs of the Student Travel Awards Committee, Matt Venesky and Cari Hickerson, reported that the Silent Auction raised $733 at the JMIH in 2009. They hope to double this amount within two years. Proposed changes to the operation of the Auction include:

1) Placing auction items on tables in the registration lobby of the JMIH to increase visibility and bidding activity.
2) Requiring Travel Award winners to monitor the Auction table.
3) Actively soliciting donations from distinguished herpetologists.
4) Creating a Facebook page to promote donations and bidding and providing information regarding applications for Student Travel Awards.

A comment was made that although the Silent Auction has traditionally focused on objects of art, last year items in the Live and Silent Auctions were very similar. This reflected a decision made by the co-chairs to expand the types of items they would accept. Matt and Cari were encouraged to think creatively about new ways to raise funds for the Student Travel Awards, e.g., games, quizzes, photo competitions.

Anne Maglia stepped down as chair of the Web Oversight Committee in March 2010. Consequently, Raul Diaz (webmaster) summarized activity relating to the SSAR webpage.

1) Homepage updated with news.
2) ZenScientist has been added where needed as the link to the page for accessing membership information.
3) Constitution, Contacts/Committees, Chairs/Officers/Editors, award winners, and Annual Meetings information updated.
4) Publications list drop menu updated with addition of: *Catalogue of American Amphibians and Reptiles, Contributions to Herpetology, Facsimile Reprints in Herpetology, Herpetological Conservation, Herpetological Circulars*.
5) Scientific and Standard English Names List Circular added as a *gratis* PDF under RESOURCES drop down tab and online version is in preparation.
6) Working with Andy Mansker (Mansker Consultation, host of the ssarherps.org page) to control access to files on the SSAR Forum.
7) We received a free upgrade in server storage from 300 to 600MB and our bandwidth also increased from 8 to 24GB. This is necessary to host the photos that will accompany the Scientific and Standard English Names page.

Elections Officer Dan Noble reported that no elections were held in 2009.

In 2009, Henry Mushinsky stepped down after many years as Coordinator of the SSAR/HL Live Auction. After some discussion, a Live Auction Committee was formed and Greg Watkins-Colwell was appointed as chair. The Live Auction raised $4048 (split 50:50 with The Herpetologists' League) in 2009. A new bidding form was used which makes receipts available for donors. A high value item was stolen from the viewing room in 2009. The Auction Committee responded with increased security and will no longer leave high-end items out for viewing (but will provide photocopies of packaging, etc.).

Al Savitzky attended the AIBS Board of Directors Meeting and the BioOne Publishers and Partners Meeting. AIBS changed its meeting model and elected to forego a general annual meeting, although it retained the annual meeting of the Council and held an annual awards ceremony.

As with many of its member organizations, AIBS has experienced decreases in both individual memberships and investment revenues, and it has consequently downsized its staff. Despite the decline in individual members, however, AIBS has retained a large number of member societies and continues to provide a strong voice for organismal and environmental biology at the national level.

The AIBS Public Policy Office launched the AIBS Legislative Action Center (www.capwiz.com/aibs) in 2009, through which the society can alert registered individuals of important issues and facilitate their responses to legislators. AIBS also maintains an active Education Office, which was heavily involved in the 2009 Year of Science and the ongoing COPUS activities. In January, 2010 AIBS initiated intensive strategic planning, to determine the most important elements of its mission, to decide how to focus its activities for the furtherance of that mission, and to examine its business model.

This year's annual BioOne Publishers and Partners Meeting included presentations by David Remsen (Global Biodiversity Information Facility) on biodiversity informatics, by Amy Brand (Harvard University) on self-archiving mandates, and by Chuck Koscher (CrossRef) on accessing an electronic publication through several alternative websites and checking manuscripts for plagiarism.

SSAR received two symposium proposals in 2010 ("Assisted Reproductive Technologies and Genetic Resource Banking: Tools for Conserving Declining Amphibians" and "Herpetology and Ichthyology Collections—the Curation of Earth's Natural History"). Based on reviews,

the SSAR Board's decision was to sponsor the first proposal by Jennifer Germano and Andy Kouba for the 2011 JMIH meetings in Minneapolis.

This concluded discussion of reports submitted, and the Board then turned to new business. The Meeting Management and Planning Committee (MMPC) made the following recommendations to convert the (ASIH) MMPC into a JMIH MMPC and to reduce expenses for future Joint Meetings:

1. Reconstruct the ASIH MMPC to be a JMIH Committee to make the committee equally responsible and responsive to the four sponsoring societies.
2. The reconstructed JMIH MMPC shall have equal representation of ichthyologists and herpetologists to ensure that we have the necessary expertise to schedule oral presentations, posters, and symposia sessions efficiently.
3. The JMIH MMPC will be composed of six voting members and one non-voting member; one voting member each appointed by the AES, HL and SSAR, and three voting members appointed by the ASIH (two ichthyologists and one herpetologist) and the non-voting Secretary of the ASIH. Other than the ASIH Secretary, each member serves a four-year term and may be reappointed as determined by the appropriate society. The Chair of the MMPC is elected from within the committee and serves a two-year term. The ASIH secretary is an *ex officio*, non-voting member and serves on the committee for the duration of the Office. Individuals serving on the ASIH MMPC shall assume their same role on the JMIH MMPC.
4. The JMIH MMPC reports directly to the four JMIH sponsoring societies.
5. All votes of the JMIH MMPC must be unanimous.
6. The reconstructed JMIH MMPC must be ratified by the four JMIH sponsoring societies.
7. Assuming that the four sponsoring societies ratify the proposed change to the MMPC, it shall become a recognized JMIH Committee.
8. Reduce the number of days of the meeting from five to four.
9. Limit the number of oral presentations to fit into the new meeting format.
10. Run seven (or at most eight) concurrent sessions (most recent past meetings have had six). Seven concurrent sessions will accommodate 630 oral presentations (eight concurrent sessions will accommodate 714 presentations).
11. Oral presentations are accepted on a first-come, first-served basis.
12. Invited presentations for approved symposia are protected (they will be included in the appropriate symposium).
13. The number of symposia will be limited to four (one per society). If a society fails to support a symposium, a replacement symposium can be offered by another society, if approved by the MMPC.
14. Oral presentations by students in award competitions are scheduled during meeting days one and two.
15. Winners of student awards are announced at the business meetings of each sponsoring society or another occasion as determined by each society. If the JMIH Banquet is retained, then each society should have the opportunity to work with the local committee and have input into the program.
16. Increase the number of poster presentations on meeting days two and three to accommodate approximately 300 poster presentations (150 per day).
17. Eliminate the end of meeting banquet (elimination of the banquet was supported strongly by the membership when polled about reducing meeting length and costs).
18. Authorize the Kansas State Division of Continuing Education to enter into a long-term agreement with a major hotel chain (e.g., Marriott, Sheraton, or Hilton) to reduce meeting costs.
19. Some proposed changes cannot take effect until 2014, because we are under contract to hold five-day meetings, others may be implemented as they become ratified by the four societies.

There was discussion of unequal representation of the participating Societies and of disciplines (i.e., three representatives from ASIH—two ichthyologists and one herpetologist) and the requirement that votes be unanimous. The argument for three ichthyologists centers around the need to have the expertise to schedule ichthyological presentations. Suggestions were made that ASIH could have three members on the Committee, but that only one would have voting privileges or that ASIH could have two voting members (an ichthyologist and a herpetologist) on the Committee. The Committee as it is currently comprised works well according to President Crother. However, concern was expressed that there was no guarantee this would continue as the committee composition changes. There was discussion of whether any decisions made by this committee could actually harm SSAR. The Board agreed that the Chair of the Committee should be an experienced member of the Committee and the position of Chair should rotate among disciplines and participating Societies. A motion to modify item 3 above such that the Committee would have five voting members (two from ASIH) was made and seconded. A vote was taken on items 1–8 above, with item 3 modified as noted (9 supported, 1 opposed). There was little discussion of most of the remaining items. Items 8, 9, 13, 14, 15, and 17 were supported unanimously (10 supported, 0 opposed). Item 16 received majority support (9 supported, 1 opposed). The Board decided that items 10, 11, and 12 did not require a vote. There was some discussion of the proposal to enter into a long-term agreement with a particular hotel chain. Questions were raised regarding the duration of such an agreement and whether the costs savings would be worthwhile. Concern was expressed that this would preclude having a university-based meeting. The Board did not support item 18 (0 supported, 10 opposed).

Discussion via email regarding the composition of the JMIH MMPC (item 3) and entering into a long-term agreement with a major hotel chain (item 18) ensued after the Annual Meeting. President Crother reported that the other three JMIH Societies (ASIH, HL and AES) approved the proposal regarding the composition of the JMIH MMPC and he recommended that SSAR should not oppose the proposal as written. He quoted from the memorandum of understanding that SSAR has previously approved: "To affirm willingness to cooperate with each other to every extent possible." President Crother also addressed the concern regarding item 18 that a long-term agreement could prevent SSAR from having a future meeting at a university. He reminded the Board that any society may meet separately with a three-year notice of its intention to do so. KState estimated that entering into an agreement with a hotel chain could result in savings of up to approximately $30,000/yr. A vote was held electronically. Eleven yes votes were received for item 3 (two votes were not received). Nine yes votes, one no vote, and one abstention were received for item 18 (two votes were not received).

The Board received a proposal for a Student Poster Award from Joe Mendelson, III and Pat Owen. Four awards each of $100 would be awarded to student members of SSAR in the following categories: Evolution, Genetics, and Systematics; Ecology, Natural History, Distribution, and Behavior; Conservation and Management; Physiology and Morphology. There was discussion of whether this award should target junior students (e.g., undergrads and Masters students), whether the Award should be money or SSAR publications, whether there should be a fifth category specifically for undergraduates, and what the grading criteria should be. A suggestion was made that the judges should factor in the status of the student (i.e., whether an undergrad or a finishing graduate student) when evaluating the poster. The Board voted to support the proposal (10 supported, 0 opposed).

Treasurer Nicholson presented a "Conflict of Interest" policy as required by the IRS. This policy was approved by the Board (10 supported, 0 opposed). Secretary Preest has since emailed this to the Board and to Editors for their signatures.

Treasurer Nicholson presented "Whistleblower," "Ethics," and "Document Destruction and Retention" policies as required by the IRS. A statement regarding timeliness in the "Ethics" policy will be modified

to read "Editors and reviewers will not intentionally delay reviewing of manuscripts for their own benefit." These policies were approved by the Board (10 supported, 0 opposed) and the "Whistleblower" and "Ethics" policies will be made available on the SSAR website.

In response to several recent requests from outside parties to pay for access to our membership lists, there was discussion of whether SSAR wishes to continue to restrict access to this list. A suggestion was made that, when members join or renew subscriptions, they could indicate the level of access that they wish other members of SSAR or outside parties to have to their personal information. Breck Bartholomew will be queried as to how difficult this would be. The consensus was that the Board wished to continue restricting access to our membership list.

Subscription agencies are currently offered a small discount if they pay renewals without being invoiced. Breck Bartholomew recommended that we discontinue this practice. The Board approved this recommendation (10 supported, 0 opposed).

There was continued discussion of an issue raised at the 2009 Board Meeting, i.e., acceptance of donations by individuals who are not members of the Society or are unknown to the Society. Concern had been expressed regarding the credentials of these potential donors, whether there are any strings attached, etc. The Board decided that donations above $500 would need to be accompanied by a statement from the donor regarding why the donation is being made, would be evaluated on a case by case basis, and must be approved by the Board before being accepted. The President would act as an intermediary between the donor and the Board should the donor wish to remain anonymous.

There was brief discussion of how the Society should handle requests to provide financial support for meetings other than JMIH and WCH. The consensus was that we did not have the financial wherewithal to provide this support.

A proposal was received to establish "The Thomas Beauvais Fund" within SSAR. The purpose of this fund would be to increase the use of color photographs, primarily of living animals and unusual and especially new species, on the interior pages of *Journal of Herpetology* and *Herpetological Review*. The proposal came with some stipulations regarding how the fund would be used, e.g., the Fund may be used *only* as a supplement or add-on to the budgets, not as a substitute for funds allocated from the Society's regular budget. The Fund may *not* be used to increase the length of issues, but only to increase their quality and attractiveness. The Board voted unanimously to accept the proposal (10 supported, 0 opposed).

A proposal was received from EBSCO Publishing to include articles from *Journal of Herpetology* on their research databases. The Board voted to sign the License Agreement (10 supported, 0 opposed) which states that the copyright of the publication remains the Society's and that EBSCO are licensing the content for inclusion on their databases.

Complimentary subscriptions and receipt of *gratis* copies of SSAR publications were discussed. This was raised in part because of a request from the co-Editors of *Journal of Herpetology* that we consider offering complimentary memberships to Associate Editors. President Crother will draft a policy regarding complimentary memberships and publications and will email this to the Board and to the Editors for their consideration.

Three SSAR Board positions are reserved for representatives of special constituencies: 1) Regional Herpetological Societies, 2) Conservation, and, 3) Non-U.S. Members. There has been some difficulty of late filling the Regional Societies position and a request was received from the Nominations Committee early in 2009 that the Board redefine this position. At the time, the Board voted electronically to retain the Regional Societies position for the 2010 election, but agreed to consider the request at the 2010 Board Meeting. After some discussion, the Board voted (10 supported, 0 opposed) to reword the Regional Herpetological Societies position. It will now be referred to as "Member at Large" and could include, for example, representatives of regional herpetological societies, members of non-governmental organizations, governmental agencies, etc.

Formation of a Membership Committee and launching of a membership campaign has been discussed at the last several Board Meetings. In the past year, informal discussions among some Editors and Officers regarding an initiative have occurred and some ideas have been generated. President Crother asked Board member Ann Paterson if she would consider chairing and forming a Membership Committee, and she agreed to do so.

There has been some turnover in the Resolutions Chair position in recent years and there was discussion of whether such a chair is necessary. The chair presents resolutions written by the Secretary at the Business Meeting. It was decided that, because this is an easy way of getting students more involved in the Society, we would retain a Resolutions Chair.

SSAR still lacks copyright agreements with authors who have published recently in our journals. Treasurer Nicholson will develop a policy and distribute it to the Board for their consideration.

A request was received by the co-Editors of *Journal of Herpetology* from the SHERPA Services Development Officer at Centre for Research Communications to encourage authors to deposit research material into open-access repositories of "e-prints." Because of concern that this would cut into royalties that we already receive (e.g. from BioOne), the Board decided to deny this request.

A balanced budget for 2011 of $263,150 was approved, and the meeting was adjourned by President Crother at 1440 h.

An informal lunchtime meeting for a number of officers, editors, and interested SSAR members was held a few days later. The main topic for discussion was the future of SSAR and the important roles that *Journal of Herpetology* and *Herpetological Review* would play in that future. Additionally, time was spent considering the possible activities of the newly reformed Membership Committee.

The Annual SSAR Business Meeting was called to order by President Crother at 1802 h on July 10th. Approximately 70 members of SSAR were in attendance. Officers, Editors, and Committee Chairs who were at the Business Meeting introduced themselves to the other attendees and gave brief summaries of their annual reports and relevant information from the Board Meeting. Chuck Crumly generously volunteered to support the soon-to-be-established Student Poster Competition.

Winners of the 2010 Dean Metter Award, Kennedy Award, Henri Seibert Student Awards, Grants in Herpetology Awards, and Student Travel Awards were announced (Fig. 7).

Rob Denton (Resolutions Chair) read the following 2010 resolutions: "SSAR wishes to thank individuals who have resigned from positions of service to the Society in the past year. At *Herpetological Review*, Margaret Gunzburger (Associate Editor) stepped down at the end of 2009. Natural History Notes Section Editors Marc Hayes and Andy Holycross also stepped down in 2009 and Barb Banbury (Copy Editor) completed her service as of late 2009. There have also been some changes for *Journal of Herpetology*. Matt Parris stepped down as Editor in late 2009. We thank him for the service he provided to the Society. SSAR thanks Erin Muths and Gad Perry who are now co-Editors of the journal. Geoff Smith, who had been the Editor before Matt Parris, is serving as interim editor to help with the transition to the two new Editors. Erik Wild who was Chair, and then co-Chair, of the Grants in Herpetology Committee for 9 years is turning over the reins to his co-chair Josh Kapfer. Pat Owen who was chair of the Seibert Award Committee is stepping down after 3 years. Anne Maglia has finished several years of service as chair of the Web Oversight Committee. Raul Diaz continues as our very hard-working webmaster. Thanks to Stu Nielsen who served as Resolutions chair for 1 year. SSAR President's Travelogues are always something to look forward to at the JMIH, and this year was no exception. Thanks to Robert Espinoza for a great presentation on "The Herpetofauna of South America's Southern Cone: New Discoveries from the Andean Peaks to the Peruvian Steppe." SSAR received a proposal for a generous donation from Thomas Beauvais in the past year. At the Board Meeting, we accepted this proposal and are establishing "The Thomas Beauvais Fund."

FIG. 7. Some of the 2010 winners of the Henri Seibert Awards with President Brian Crother. Clockwise from top L. Scott Farnsworth (Honorable Mention, Conservation section), Dan Leavitt (Winner, Conservation section), Cameron Siler (Winner, Systematics/Evolution section), Brian Crother, Jennifer Stynoski (Winner, Ecology section), and Oliver Hyman (Honorable Mention, Ecology section). Denita Weeks was the winner in the Morphology/Physiology section (see Fig. 2)

The purpose of this fund is to increase the use of color photographs, primarily of living animals and of unusual and especially new species, on the interior pages of issues of *Journal of Herpetology* and *Herpetological Review*. The herpetological community is most grateful for this generosity, which will lead to greater appreciation of the scientific and esthetic qualities of the animals we study. We also received a donation this past year from Tim Criswell towards the Grants in Herpetology Award. Thanks to Chuck Crumly of University of California Press for his continued support of Seibert Award winners. Congratulations to Whit Gibbons who is this year's winner of the new multi-Society Meritorious Teaching Award in Herpetology. SSAR reached the end of an era this year with the publication of Vol. 22 of *Biology of the Reptilia*. Carl Gans was the originator and senior editor of this series, that he envisioned as facilitating "future work" and proving "germinal in inducing additional study." One hundred sixty-nine authors from 21 countries contributed chapters on morphology, behavior, ecology, development, neurology, and physiology beginning in 1969 with the publication of Volume 1. SSAR was immensely proud to assume publication of this series in 1998 with Volume 19 (Morphology G: Visceral Organs). Since then, we have published Volume 20 (Morphology H: The Skull of Lepidosauria), Volume 21 (Morphology I: The Skull and Appendicular Locomotor Apparatus of Lepidoasuria), and then, in March of this year Volume 22 by Ernest A. Liner (Comprehensive Literature of the Reptilia). Kraig Adler was co-Editor (with Carl Gans and Abbot Gaunt) of several of the last volumes of *Biology of the Reptilia* and SSAR extends its gratitude to Kraig for seeing this series through to completion. Finally, SSAR thanks the many members who serve in various capacities—continuing officers, editors, and members of committees, judges of student competitions, reviewers of manuscripts submitted to our journals, contributors to the Live and Silent Auctions, as well as those who attend these Joint Meetings."

FIG. 8. The traditional passing of the gavel from President Brian Crother to President-Elect Joe Mendelson, III occurred at the end of the SSAR Business Meeting. (Photo M. Preest)

President Brian Crother, who comes to the end of his term in December, then turned over the SSAR gavel to President-Elect Joe Mendelson, III (Fig. 8), and the 2010 Business Meeting was adjourned at 1915 h.

—Respectfully submitted by Marion Preest, SSAR Secretary

Seibert Award Winners for 2010 Announced

The 19th annual Seibert Awards were presented at the 53rd Annual Meeting of the SSAR in Providence, Rhode Island, 7–12 July 2010. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). In recognition of outstanding student presentations at the annual meeting, a single award was given in each of the following categories: Evolution/Systematics (9 presentations), Ecology (12 presentations), Physiology/Morphology (6 presentations) and Conservation (8 presentations). All awardees will receive a check for US $200 and a book from Chuck Crumly at University of California Press.

The Winners—Systematics/Evolution: **Cameron Siler** and Rafe Brown, University of Kansas, "Historical processes behind patterns of limb reduction and loss in an island radiation of fossorial lizards." Ecology: **Jennifer Stynoski**, Virginia Noble, Meredith Strider, University of Miami, Organization for Tropical Studies, University of Maryland, "To eat but not to be eaten: honest begging signals and visual detection of predators and mothers by tadpoles of the Strawberry Poison Frog (*Oophaga pumilio*)." Physiology/Morphology: **Denita M. Weeks** and Robert E. Espinoza, California State University, Northridge, "Geckos on ice: unexpected thermal tolerances and temperature-dependent performance of the world's southernmost gecko." Conservation: **Daniel Leavitt**, Texas A&M University, "*Sceloporus arenicolus*, an endemic lizard in an endangered ecosystem."

Honorable Mention—Systematics/Evolution: **Philip L. Skipwith**, Aaron M. Bauer, and Todd R. Jackman, Villanova Univer-

sity, "Molecular phylogenetics of New Caledonian diplodactylid geckos." Ecology: **Oliver Hyman** and James P. Collins, University of Arizona, "Negative influence of phosphorus on prevalence of the frog killing pathogen, *Batrachochytrium dendrobatidis*." **James Paterson**, Brad Steinberg, and Jacqueline Litzgus, Laurentian University, Algonquin Park, "Comparisons of hatchling survivorship and spatial ecology between two sympatric turtle species." Physiology/Morphology: **Travis Hagey**, Luke Harmon, and Kellar Autumn, University of Idaho, Lewis and Clark College, "Predicting adhesive capabilities in *Anolis* and *Phelsuma* lizards via the frictional adhesion model and critical detachment angle." Conservation: **Scott Farnsworth** and Richard Seigel, Towson University, "Short and long distance translocations of Eastern Box Turtles: Do fences make good neighbors or conservation practices?"

The judges were Cathy Bevier (Colby College), Rafe Brown (University of Kansas), Tiffany Doane (Central Connecticut State University), Nirvana Filoramo (Wesleyan University), Mac Given (Neumann College), Noah Gordon (University of Evansville), Eric Juterbock (The Ohio State University), and Patrick Owen (University of Cincinnati).

Metter Award Application Period Open

Dean E. (Doc) Metter (1932–2001) was a long-time member of the biology faculty at the University of Missouri-Columbia, where he taught zoology, comparative anatomy, evolution, and herpetology. A believer in putting knowledge to the test in the field, Doc provided frequent opportunities for students to engage in fieldwork. In addition, he frequently assisted his graduate students as they ventured out to collect data. Doc was a co-founder of the Bobby Witcher Society, the legacy of which is a scholarship fund. For many years, the interest earned served to reward outstanding herpetology students who intended to continue their education and seek a career in vertebrate biology. That fund now serves a similar purpose by honoring Doc's memory while helping to fund the SSAR-administered Dean E. Metter Memorial Award.

The deadline for receipt of applications for the 2011 Metter Awards is 30 March 2011. Successful applicants must be current members of SSAR as of 31 December 2010. For details of eligibility and application requirements, please check the SSAR web page: http://www.ssarherps.org/pages/metter.php

SSAR Participation at the USA Science & Engineering Festival, Washington, DC 23–24 October 2010

The Society for the Study of Amphibians and Reptiles participated in the recent inaugural USA Science & Engineering Festival by hosting an interactive booth highlighting SSAR and the animals we study. The event was massive, with many hundreds of booths and several stages stretching down the National Mall and occupying several other nearby sites. The 10 ft x 10 ft SSAR booth was outdoors in Woodrow Wilson Plaza next to the Ronald Reagan Building on Pennsylvania Avenue. Our booth was situated between booths sponsored by *Scientific American* and NASA, and just opposite a very large booth sponsored by Lockheed Martin. These booths were directly behind the main stage for the plaza, that featured everything from science-themed musical acts, scientific cuisine demonstrations, an Albert Einstein impersonator, and the Science Cheerleaders (science majors drawn from cheerleading squads of regional universities). So, we were ideally located in a very high traffic location.

FIG. 1. Novel SSAR logo created for souvenir stamp for the USA Science and Engineering Festival. Actual size of imprint is ½" x ½".

The booth displayed a representative selection of SSAR publications including *Journal of Herpetology, Herpetological Review, Urban Herpetology, Biology of the Reptilia* series, the standard names checklist, books from the facsimile series, and others. Distribution of brochures or other handouts was greatly discouraged by the organizers of the event (for reasons of litter control), so the newly printed SSAR Membership brochures were held back and handed individually only to persons who appeared genuinely interested in the society. The booth displayed a variety of real and replica skulls, shells, and fangs of reptiles. We also had a live American Toad, Corn Snake, and Eastern Box Turtle. As expected, the live animals and impressive skeletal specimens were a huge draw and we regularly had visitors lined up five-deep at the booth awaiting their turn to examine and touch them—and to discuss them with the SSAR members and officers in the booth. The publications received a bit less attention—it is hard for a book to compete with real, live animals!—but were of sufficient interest to some that a few copies "went missing" over the course of the weekend. However, the impressive cover images on *Herpetological Review* engendered considerable discussion, especially those of *Crotalus lannomi* (by Ginny Weatherman et al.) and the tadpoles of *Anotheca spinosa* filled with nutritive eggs (by Danté Fenolio).

The attendees were primarily families and, typical of the DC metropolitan area, represented many nations worldwide. Kids and parents interacted with our staff and exchanged questions and stories and generally marveled at the materials on display. A number of people marveled at the fact that it was possible to make a career out of the study of amphibians and reptiles; more than a few young people seemed truly inspired by that real possibility. The booth staff seemed proud to relate that they had the most exciting careers and hobbies imaginable; we truly held our own

FIG. 2. Kyle Miller Hesed and Steve Gorzula braving the mass attendance at the SSAR booth at the USA Science and Engineering Festival.

with the "competing" astronauts in the adjacent booth! Most of the attendees had festival-sponsored folios or "science passports" and were rabid in their efforts to collect stamps from as many booths as possible. We prepared a novel SSAR stamp for the occasion (Fig. 1), and many kids were thrilled to have the SSAR frog also applied to their hand (or even forehead!) as a "tattoo." Next year we need special SSAR T-shirts for the booth staffers, and stickers or buttons to decorate the young people!

FIG. 3. George Zug interpreting a live Corn Snake for a young woman attending the SSAR booth.

Given the contemporary popularity of herps as pets, and their ubiquity in classrooms and education programs at museums, nature centers, and zoos, it was surprising to see how many of the attendees had never touched or held a live reptile before. A great number of people touched their first snake or turtle at the SSAR booth at the Science Festival in 2010, an experience they are not likely to forget. At the other extreme, it was rewarding to meet so many people—especially young people—who were remarkably learned and respectful towards amphibians and reptiles. We met 12-year olds who knew the difference between elapids and vipers, or who knew about the amphibian chytrid fungus.

The evident success of the weekend event was bolstered by spectacularly beautiful Fall weather and extraordinarily smooth logistics and planning on the part of the organizers. The event was promoted by President Obama and covered by major media. The National Park Service has conservatively estimated an astounding attendance between 750,000–1,000,000 persons. We can be proud to truthfully say that SSAR, in keeping with its mission, reached out and "brought herpetology to the people" in a booth staffed by members including hobbyists, career academics, and students (Figs. 2, 3).

Credits: Brian Crother suggested and initiated SSAR participation in the event; Joe Mendelson handled pre-festival arrangements; Karen Lips led intra-DC logistics and volunteers for the booth; Joe Mendelson and Karen Lips managed daily set-up and break-down of the booth and staffed it for both days; use of live animals was facilitated by Jim Murphy and Robin Saunders, with animals courtesy of Long Branch Nature Center; viper fang displays were prepared and loaned by Jason Brock; skeletal specimens were loaned by Education Department at Zoo Atlanta; Breck Bartholomew selected and shipped representative SSAR publications. Volunteer staff at the booth were Anne Maglia, George Zug, Roy McDiarmid, Ted Kahn, Jake Li, Kyle Miller Hesed, Peter Uetz, Brian Gratwicke, Steve Gorzula, and Jim Murphy.

—Submitted by Joseph R. Mendelson, SSAR President-Elect

2011 Year of the Turtle

Partners in Amphibian and Reptile Conservation (PARC), along with many partners (IUCN Tortoise and Freshwater Turtle Specialist Group, Turtle Survival Alliance, Chelonian Taxonomic Advisory Group, The Turtle Conservancy, and a growing list of others) are designating 2011 as "Year of the Turtle." We invite SSAR members to join our efforts! This is an opportunity to raise awareness of efforts in research, conservation, and education to benefit these animals. Throughout the year there will be a number of activities including monthly newsletters featuring conservation or research efforts, local events and presentations, official reports and meeting highlights, a photo contest and release of monthly calendar pages with selected photos, and educational materials for teachers and children, including arts, humanities, and cultural values relating to turtles. Please contact Dede Olson (dedeolson@fs.fed.us) or Priya Nanjappa (pnanjappa@fishwildlife.org) if you'd like to assist or to contribute information toward the newsletter or related resources.

NEWSNOTES

2010 IUCN Crocodile Action Plan

The IUCN-SSC Crocodile Specialist Group recently released the 2010 Action Plan for Crocodiles, which includes summary accounts for the world's 23 crocodile species. Accounts for all species can be downloaded here:

http://www.iucncsg.org/ph1/modules/Publications/ActionPlan3/ap2010_index.html

The current IUCN Red List (http://www.iucnredlist.org/) descriptions for threatened crocodilians will eventually be updated with these accounts. Please note that the distribution maps for Tomistoma and Siamese Crocodile contain some errors which escaped the editing process, and the maps will be corrected and re-uploaded to the CSG website within the next few months.

Retirement of Wolfgang Böhme

Prof. Dr. Wolfgang Böhme, for 40 years head of the herpetology department at Museum A. Koenig in Bonn, Germany will retire on December 1, 2010. During his long tenure as curator, he advanced the Koenig to the first rank of herpetological collections in Germany and it became one of the most active herpetological research centers in the world. In addition to his curatorial duties, he supervised a large number of masters and doctoral students at the University of Bonn.

SSAR members will recall Prof. Böhme's outstanding keynote lecture on West African herpetology delivered at its 2002 meeting in Kansas City. This was his first visit to the United States. SSAR salutes Prof. Böhme on his retirement.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (HerpReview@gmail.com) well in advance of the event.

11–14 January 2011—10th Conference of the Herpetological Association of Africa, Cape Town, South Africa. Information: https://sites.google.com/site/10haacapetown/

18–20 February 2011—36th Annual Symposium of the Desert Tortoise Council, Las Vegas, Nevada, USA. Information: www.deserttortoise.org

23–27 May 2011—Second Mediterranean Congress of Herpetology, Marrakech, Morocco. Information: http://www.ucam.ac.ma/cm2

19–22 June 2011—Sixth Hellbender Symposium, Ligoneer, Pennsylvania, USA. Information: mcmillan@buffalostate.edu

6–11 July 2011—Joint Meeting of Ichthyologists and Herpetologists (ASIH / HL / SSAR), Minneapolis, Minnesota, USA. Information: http://www.dce.k-state.edu/conf/jointmeeting/

2–7 September 2012—4th International Zoological Congress (IZC), Mount Carmel Campus, University of Haifa, Haifa, Israel. To receive the first and subsequent meeting announcements, contact the organizers at: izc2012@sci.haifa.ac.il.

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Joshua Hale or Ben Lowe; postal and e-mail addresses may be found on the inside front cover.

A listing of current contents of various herpetological journals and other publications is available online. Go to: http://www.herplit.com and click on "Current Herpetological Contents."

Surface Currents Assist Estuarine Crocodiles in Completing Long Distance Movements

The Estuarine Crocodile, *Crocodylus porosus*, is the largest living reptile and its wide geographic distribution throughout the southwestern Pacific and eastern Indian Oceans (including far-flung oceanic islands) suggests that it is capable of extended ocean travel. Further, no island speciation has occurred, suggesting that this type of movement is relatively common. *C. porosus* have been known to travel up to 30 km across the ocean in a single day, and are capable of consecutive days of more than 20 km, which is remarkable for an animal that is believed to have modest aerobic capacity. In this study, the authors have investigated long-distance movement in *C. porosus*. Acoustic telemetry was used to measure movement along the North Kennedy River, North Queensland, Australia. Results showed that long distance (greater than 10 km), single direction travel was restricted to when tidal currents were moving in the same direction. Further, when surface current direction became unfavorable, individuals would dive, or retire to the river bank. Satellite tracking of tagged crocodiles on ocean travel resulted similar findings, with a strong correlation between the direction of travel and the residual surface current. Using this strategy, one crocodile was able to complete a 560 km journey along the west coast of the Cape York Peninsula in only 25 days. Another satellite tracked individual made a significant ocean movement, only to return to its original home range. The discovery that these crocodiles use of surface currents for long distance movement has management consequences, particularly if changes in ocean currents result in them traveling to areas where there is no recent history of their presence and putting them into contact with humans, to which they pose a significant risk.

Furthermore, translocations of problem crocodiles, a common management strategy, need to take place where prevailing currents do not allow a rapid passage back to their original location.

Extreme Longevity in the Human Fish

The human fish or olm, *Proteus anguinus* (Proteidae), is an aquatic, paedomorphic, cave-dwelling salamander native to the European countries Slovenia and Croatia. As captive specimens have been known to live for over 70 years, this species has long been of interest to biologists studying aging and senescence. Extreme lifespan has been demonstrated in a number of taxa, including mammals, birds and reptiles, and is usually positively correlated with size. However, the Human Fish is small, generally less than 20 g. Longevity has also been associated with living in environments that are stable and/or free from predators, the possession of mechanisms that mitigate damage caused by free radicals, and slow metabolisms. It is cave dwelling and therefore lives in a stable environment, and is thought to not suffer from predation. Additionally, it has been shown not to possess advanced cellular oxidation defences; the metabolic rate of *Proteus* is unknown. A breeding colony, established in a cave in Saint-Girons, France in 1952, now has over 400 individuals of various age classes, allowing the authors of this paper to conduct a detailed investigation of the demographic and physiological characteristics of this species. Data on physical condition and instances of birth and death (collected weekly) reveal that the population is growing at a rate of 1.05, olms reach sexual maturity at roughly age 15, reproduce once every 12 years, and average adult lifespan is roughly 70 years. From these data, the researchers determined that the maximum lifespan for this species is 102 years. Furthermore, while salamanders exhibit reduced metabolic rates relative to other vertebrates, laboratory experiments found the metabolism of the human fish to not be markedly different from other salamanders. While the proximate mechanisms leading to longevity in the human fish remain elusive, it does represent an excellent model organism for studying longevity and senescence in vertebrates.

Voituron, Y., M. de Fraipont, J. Issartel, O. Guillaume and J. Clobert. 2010. Extreme lifespan of the human fish (*Proteus anguinus*): a challenge for ageing mechanisms. Biology Letters doi:10.1098/rsbl.2010.0539.

Tadpoles Recognize Native but not Introduced Turtle Predators

The impact of introduced predators on prey populations is well known, but less research has been conducted on the negative effects on native species of having to compete with these alien species. On the Iberian Peninsula, the native freshwater turtles (the European pond turtle, *Emys orbicularis* and the Spanish terrapin, *Mauremys leprosa*), are being displaced by exotic species (principally the red-eared slider, *Trachemys scripta elegans* and the false map turtle, *Graptemys pseudogeographica*). Both native and introduced species feed on anuran tadpoles, which are able to recognize local predators and alter their behavior. In this study the authors have examined tadpole responses to both native and introduced species in order to determine whether they can recognize introduced species as well. Chemical cues of the four turtle species mentioned above were presented to tadpoles of four species of European anurans: Iberian green frog (*Pelophylax perezi*), western spadefoot (*Pelobates cultripes*), natterjack toad (*Bufo calamita*), and common gree frog (*Hyla arborea*). Three species (*P. perezi*, *P. cultripes* and *H. arborea*) reduced their swimming behavior in response to native, but not introduced species. The authors suggest that a lack of evolutionary experience with the introduced predators explains the inability of the tadpoles of these species to detect them and may confer a competitive advantage to the introduced turtle species.

Cane Toad Eggs Toxic to Tadpoles of Native Australian Anurans

The introduced Cane Toad, *Bufo* (= *Rhinella*) *marninus*, is inflicting a number of profound impacts on native species as it expands across Australia. Previous studies have shown cane toad eggs to be extremely toxic to the tadpoles of native Australian anurans and in this study, the authors have conducted a number of laboratory trials to determine if there is variation among tadpoles of Australian species in propensity to consume cane toad eggs or susceptibility to toad egg toxins. In each trial, individual tadpoles were presented ten cane toad eggs either with or without an additional food source (lettuce). At least some individuals of each of the 15 anuran species studied ingested toad eggs, with mortality following rapidly in most cases. While no interspecific difference in propensity to ingest eggs was observed, the high interspecific variance in survival rate (0 > 70%) was driven by a difference in feeding behavior (e.g., small size preventing efficient consumption of toad eggs) rather than physiological tolerance. Furthermore, alternative food sources did not reduce mortality from egg ingestion as most tadpoles foraged on both the eggs and the lettuce. The influence of overall body size on

survival was also examined in four species. While three of the species did show an effect of body size on mortality, this was not in a consistent direction, and instead was a complex interaction related to alternate food availability. Interclutch affects were examined in one species, but none were observed. This study highlights the toxicity of toad eggs to native frogs and that frequency of mortality relates to a complex interaction between body size, species and other ecological factors.

How Much UV-B Should a Captive Reptile be Exposed to?

Ultraviolet-B (UV-B) exposure is important to the production of Vitamin D in many vertebrate species, including reptiles, and plays a part in calcium-phosphorous balance and immune function. The amount of UV-B to provide is therefore an important consideration to ensure the good health of captive reptiles. In this study, the authors have investigated voluntary UV-B exposure of a number of squamate species in the wild, in the US and Jamaica. In Jamaica, three species of *Anolis* (*A. lineotopus, A. grahami,* and *A. sagrei*) were investigated. In the US, *Agkistrodon piscivorous, Pantherophis obsoletus, Thamnophis proximus, Nerodia fasciata, N. erythrogaster, Uta stansburiana, Holbrookia maculata, Sceloporus olivaceus, S. consobrinus, S. undulatus, S. graciosus,* and *Anolis carolinensis* were studied. Animals encountered in the field were subjected to cloacal temperature readings and UV-B readers were employed to ascertain the level of UV-B exposure the animals were experiencing. The authors found significant variation among species in UV-B exposure; more extensive observations of two species of *Sceloporus* (*S. olivaceus* and *S. graciosus*) revealed seasonal and diel variation as well. The authors provide a number of guidelines for providing UV-B to these species in captivity. They also highlight the importance of providing a UV-B refuge in enclosures to allow behavioral regulation of UV-B exposure.

Ferguson, G. W., A. M. Brinker, W. H. Gehrmann, S. E. Bucklin, F. M. Baines and S. J. Mackin. 2010. Voluntary exposure of some Western-Hemisphere snakes and lizard species to ultraviolet-B radiation in the field: How much ultraviolet-B should a lizard or snake receive in captivity? Zoo Biology 29:317–334.

Behavioral Syndromes, or "Personalities" Investigated in a Lizard

Behavioral syndromes ("personalities") are increasingly being recognized as an important component of natural systems, having been observed in fish, invertebrates, mammals, and reptiles. In this paper, the authors have examined behavioral syndromes in the Namibian Rock Agama, *Agama planiceps*. To determine if individuals displayed consistent magnitudes of boldness or shyness, investigators measured flight initiation distance (the distance away a perceived threat, in this case an advancing experimenter, was from the lizard before it fled) for a number of individuals several times over a period of time. Next, male lizards were observed and their behavior (instances of head bobbing and push ups; collectively defined as "signaling") was documented. Finally, possible fitness consequences of boldness or shyness was investigated by measuring the home ranges, rates of tail loss, and feeding rates of several males. Individuals were found to exhibit consistent degrees of boldness. Bold males spent more time basking and moving and had larger home ranges and higher feeding rates than shy males. The rate of signaling behavior however, did not differ between bold and shy individuals. Males that had a third or more of their tale missing were more likely to be bold, suggesting that there may be an increased predation risk associated with being bold. The authors suggest that long term studies are required to fully understand the fitness consequences of animal personalities such as boldness.

Carter, A. J., A. W. Goldizen, and S. A. Tromp. 2010. Agamas exhibit behavioral syndromes: Bolder males bask and feed more but may suffer higher predation. Behavioral Ecology doi: 10.1093/beheco/arq036.

Roads Act as Barriers to Seasonal Migration in Timber Rattlesnakes

Anthropogenic landscape modification, especially roads, can fragment habitats and act as dispersal barriers to wildlife. However, the degree to which a road acts as a barrier to dispersal is related to characteristics both of the road itself and the animal in question. In this study, the authors have examined the impact of recently constructed roads separating hibernacula (communal dens) of timber rattlesnakes, *Crotalus horridus* in four regions in New York State, USA. Microsatellites were used to examine population subdivision and gene flow across roads. It was found that hibernacula separated by roads had a higher degree genetic differentiation than hibernacula in contiguous habitat and also were less genetically diverse. This was further examined by completing genetic assignment analyses, which showed that disruption of seasonal migration was the cause of these patterns, with matings less likely to occur between snakes from hibernacula separated by roads. This study highlights the fragmenting nature of roads, even those that are relatively small, or recent in origin.

Clark, R. W., W. S. Brown, R. Stechert and K. R. Zamudio. 2010. Roads, interrupted dispersal, and genetic diversity in timber rattlesnakes. Conservation Biology 24:1059–1069.

The Island of Bermuda Preserves an Ancient Skink Lineage

Paleoendemism is the preservation of ancient, formerly widespread lineages in a restricted geographic area. Islands can be good sources of paleoendemism, with the most well known example being that of the Tuatara, which was once widely-distributed, but is now restricted to islands off the shores of New Zealand. The native fauna of the island of Bermuda includes only a single extant flightless terrestrial vertebrate: the endemic scinid lizard, *Plestiodon longirostris*. In this study, the authors have assembled a multi-locus molecular dataset which they used to reconstruct a phylogeny and estimate divergence times, which were in turn used to determine if colonization of Bermuda was recent or ancient. They found that the lineage occuring on Bermuda is indeed ancient, having split from the lineage containing its closest extant relatives before the bulk of the diversification events that led to the divirsity of skink species occurring in North America today (about 16 million years ago). Furthermore, the extant members of the clade from which the Bermuda Skink split occur in western North America (*P. skiltonianus* complex), with no extant eastern North American representatives. Even more interestingly, it is found only on Bermuda currently, which is itself only 2 million years old. Fossil evidence of *P. longirostris* on Bermuda from 400,000 years ago suggests that colonization occurred between 2 million and 400,000 years ago, possibly by rafting the 1000 km that separates Bermuda from the North American mainland (where they once existed). Following colonization, the lineage then disappeared from the mainland. Bermuda therefore, represents a unique 'life raft,' preserving one of the most ancient lineages of North American *Plestiodon.* Currently however, habitat destruction and degradation and pressure from non-native species has severely lowered population size, resulting in this unique lizard being highly endangered.

Brandley, M. C., Y. Wang, X. Guo, A. N. Montes de Oca, M. F. Ortíz, T. Hikida and H. Ota. 2010. Bermuda as an evolutionary life raft for an ancient lineage of endangered lizards. PLoS ONE 5: e11375.

Newly Discovered Chameleon Species Highlights Importance of Preserving Biodiversity Hotspots

Madagascar has the dubious distinction of being among the most imperiled biodiversity hotspots on earth. However, despite a mere 17% of its original vegetation remaining, Madagascar continues to divulge species new to science. The authors of this paper describe a distinctive new species of chameleon, *Calumma tarzan*, from three localities on the eastern slope of the island (Anosibe An'Ala region). This species exhibits morphological traits consistent with the *Calumma furcifer* species group. However, it possesses a unique rostral spade, and males have a distinctive dorsal brown blotch on the head and neck. A molecular analysis confirms the phylogenetic placement of this new taxon, follows previous analyses in failing to resolve relationships within the *C. furcifer* species group, corroborates the evolutionary distinctiveness of these lizards, and suggests two genetically differentiated populations (north and south). The specific epithet is derived both from the former name of a nearby village, Tarzanville (now Ambatofotsy), and the fictional forest denizen, Tarzan. As *C. tarzan* is known to occupy less that 10 km^2, the authors posit that it should receive the IUCN's Critically Endangered listing. They also point out the lack of protected land in this region (amounting to a "reserve gap") and hope the patronym brings attention to this overlooked region and compels conservation efforts.

Gehring, P. S., M. Pabijan, F. M. Ratsoavina, J. Köhler, M. Vences, and F. Glaw. 2010. A Tarzan yell for conservation: A new chameleon, *Calumma tarzan* sp. n., proposed as a flagship species for the creation of new nature reserves in Madagascar. Salamandra 46:167–179.

Habitat Preferences and Home Range Size in a Colubrid Snake

Effective wildlife conservation plans should consider both the habitat needs and spatial requirements of the species in question. Studies that focus on the correlation between the habitat preferences and movement patterns of wildlife, particularly snakes, are uncommon. In this study, the authors attempted to determine how habitat preferences or quality influenced movement patterns of snakes. To answer this question, they used habitat preference or avoidance information obtained for Bullsnakes (*Pituophis catenifer sayi*) from 2003–2005 at a site in the upper-midwestern United States and compared it to minimum convex polygon estimates of home range size derived from data on radio-tracked snakes. They employed Geographical Information Systems to model the amount of preferred (open bluff faces) and avoided (agricultural fields and closed canopy forests) habitats within each estimated home range and compared them via multiple linear regression. They also tested the influence of gender, length and weight on home range size. The results of this study indicated that, among the investigated potential correlates, amount of avoided habitat was the most significant indicator of home range size. More specifically, home range size increased with amount of avoided habitat within the home range. As bullsnakes are large snakes**,** they ar**e** particularly susceptible to road mortality; therefore, fragmentation of suitable habitat forces snakes to wander further in the search for suitable habitat, exposing them to greater risk. In a broader context, this finding supports the hypothesis that habitat quality has an impact on wildlife movement patterns, and the relationship between habitat needs and spatial requirements should be considered when conserving or managing species.

Kapfer, J. M., C. W. Pekar, D. M. Reineke, J. R. Coggins, and R. Hay. 2010. Modeling the relationship between habitat preferences and

home-range size: A case study on a large mobile colubrid snake from North America. Journal of Zoology 282:13–20.

Multi-year Study of Toad Populations Reveals Demographic Implications of Chitrid Fungus

While many studies have implicated *Batrachochytrium dendrobatidis* (Bd) infection in population declines, few have studied natural populations for multiple years to elucidate the specific demographic impact of the disease. The authors of this study conducted a six-year capture-recapture study on three populations of western toad (*Bufo* [= *Anaxyrus*] *boreas*) in the Rocky Mountains of western US. Of these populations, two were infected with Bd and one was not. Captured animals were individually marked (if first capture), measured, swabbed to determine if the animal was infected with Bd, and released. From these data, population growth rates were obtained and analyses were conducted to determine if growth rates were correlated with various factors such as the presence or absence of Bd and climactic conditions (e.g., breading season temperature). Roughly 58% of individuals in the two Bd-infected populations were found to be infected with the disease. These infected animals were found to have an annual survival coefficient of about 0.47 (about 0.75 for uninfected individuals). Bd-infected populations were found to be declining by roughly 6% per year over the duration of the study while the Bd-free population exhibited stable population growth. Furthermore, population growth rates were not correlated with temperature. These findings reveal that in addition to causing rapid local extirpations, in some instances, Bd can also exhibit long-term persistence as a chronic disease (and that some species can persist with Bd). Furthermore, this study highlights the need for long-term monitoring of amphibian populations to determine the species-specific demographic impacts of pathogens.

ZOO VIEW

Snake Versus Rabbit

This colorful excerpt was sent by Jon Coote about the Tower of London and the last director, Alfred Cops, who took over the operation in 1822.

Mr. Broderip, in the second volume of the *Zoological Journal*,

"Mr. Cops of the Lion Office in the Tower," writes Broderip, "sent to inform me that one of these reptiles had just cast his skin, at which period they, in common with other serpents, are most active and eager for prey. Accordingly I repaired with some friends to the Tower, where we found a spacious cage, the floor of which consisted of a tin case covered with red baize and filled with warm water, so as to produce a proper temperature. There was the snake, " positis novus exuviis," gracefully examining the height and extent of his prison as he raised, without any apparent effort, his towering head to the roof and upper parts of it, full of life, and brandishing his tongue.

A large buck rabbit was introduced into the cage. The snake was down and motionless in a moment. There he lay like a log without one symptom of life, save that which glared in the small bright eye twinkling in his depressed head. The rabbit appeared to take no notice of him, but presently began to walk about the cage. The snake suddenly, but almost imperceptibly, turned his head according to the rabbit's movements, as if to keep the object within the range of his eye. At length the rabbit, totally unconscious of his situation, approached the ambushed head. The snake dashed at him like lightning. There was a blow—a scream—and instantly the victim was locked in the coils of the serpent. This was done almost too rapidly for the eye to follow: at one instant the snake was motionless : in the next he was one congeries of coils round his prey. He had seized the rabbit by the neck just under the ear, and was evidently exerting the strongest pressure round the thorax of the quadruped ; thereby preventing the expansion of the chest, and at the same time depriving the anterior extremities of motion. The rabbit never cried after the first seizure:—he lay with his hind legs stretched out, still breathing with difficulty, as could be seen by the motion of his flanks. Presently he made one desperate struggle with his hind legs; but the snake cautiously applied another coil with such dexterity as completely to manacle the lower extremities, and, in about eight minutes, the rabbit was quite dead. The snake then gradually and carefully uncoiled himself, and, finding that his victim moved not, opened his mouth, let go his hold, and placed his head opposite to the fore part of the rabbit. The boa generally, I have observed, begins with the head ; but in this instance the serpent, having begun with the fore-legs, was longer in gorging his prey than usual, and in consequence of the difficulty-presented by the awkward position of the rabbit, the dilatation and secretion of lubricating mucus were excessive. The serpent first got the fore-legs into his mouth; he then coiled himself round the rabbit, and appeared to draw out the dead body through his folds; he then began to dilate his jaws, and holding the rabbit firmly in a coil as a point of resistance, appeared to exercise at intervals the whole of his anterior muscles in protruding his stretched jaws and lubricated mouth and throat at first against, and soon after gradually upon, and over his prey. The curious mechanism in the jaws of serpents which enables them to swallow bodies so disproportioned to their apparent bulk is too well known to need description; but it may be as well to state that the symphysis of the under jaw was separated in this case, and in others which I have had an opportunity of observing. When the prey was completely ingulphed, the serpent lay for a few moments with his dislocated jaws still dropping with the mucus which had lubricated the parts, and at this time he looked quite sufficiently disgusting. He then stretched out his neck, and at the same moment the muscles seemed to push the prey further downwards. After a few efforts to replace the parts,

the jaws appeared much the same as they did previous to the monstrous repast."

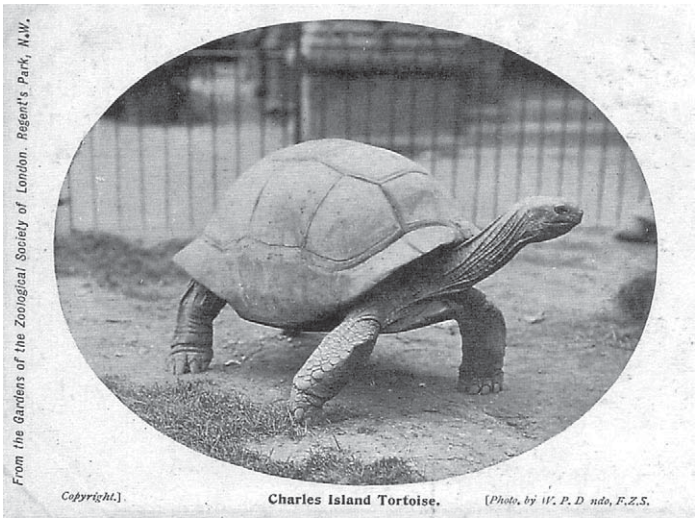
Headline from *New York Times*:
Raymond L. Ditmars Urges "Suppression" of Immoral "Ragtime"

Raymond J. Novotny sent this letter written by Raymond L. Ditmars to the editor of the *New York Times*, published on 13 October 1912. I wonder which song he was referring to as the term "Ragtime" was used for many songs, especially those by Scott Joplin. If Ragtime tunes were unsettling to Ditmars, I wonder what his response would be watching and listening to today's rock bands. This letter offers a glimpse into the character of the man.

To the Editor of the New York Times:

Coming into town in a smoking car a few nights ago, I listened to a very suggestive song rendered by a crowd of young rowdies. I thought little of the matter at the time, as the song appeared to be their own composition. Yesterday morning I was startled to hear two little girls on their way to school singing the chorus of this song. Inquiry at a cheap music store brought me the information that this composition was one of the latest "popular" songs. It follows in the wake of objectionable portrayals of marital infidelity, risque situations, and crude twistings of coarse phrases.

It seems remarkable to me that nothing is being done to stamp out the epidemic of these positively dangerous songs, the titles of which are now stock phrases around town, and all too common from the lips of children. There has been much ado about suppressing objectionable literature, cleansing the stage, even subjecting the motion picture playlets to a board of censorship. Yet songs that are clearly immoral are being issued with unabated energy—even sung by little girls on their way to school.



—RAYMOND L. DITMARS
New York, October 9, 1912

And Then There Was One

Whenever a book appears on the scene with a title like *The Last Tortoise: A Tale of Extinction in Our Lifetime* (2010, The Belknap Press of Harvard University Press, Cambridge, Massachusetts & London, England ISBN 978-0-674-04992-5) by Craig B. Stanford, it is clear that this will not be an uplifting read. In fact, tortoises are under siege worldwide, caused by a number of human-induced pressures, and Stanford covers all of these usual factors in depth: habitat alteration, collection for exotic animal pet trade, human food and medicine, climate change and so on. In Chapter 6 of the book called "Beloved Captives," he paints a grim picture of the future of these pet tortoises. One of the examples he gives is the discovery of several dozen Radiated Tortoises from Madagascar in a pet market in Thailand, probably illegally sent from the range country. A full review of this book appears elsewhere in this issue, prepared by John Moriarty.

Undated postcard of child riding a Galápagos Tortoise named "Grandpa" at New York Zoological Society. Zoos no longer offer tortoise "rides." Credit: provided by Brint Spencer.

Official postcard of Zoological Society of London depicting Charles Island [Santa María or Floreana] Tortoise (*Geochelone elephantopus*, now *Geochelone n. nigra*) at London Zoo from series of postcards available to the public in October 1904. This species is now extinct. Author Craig Stanford in his book *The Last Tortoise* describes how vulnerable tortoises are today, facing the real danger of disappearing from the planet for all time. Credit: photographed by W. P. Dando, provided by John Edwards.

Some years ago, the late John Behler from the Wildlife Conservation Society in New York called me after resurveying tortoise populations in Madagascar and discovering that hundreds, perhaps thousands, of Radiated Tortoises had been killed for their livers to make pâté for the Asian food market. Dead tortoises and empty shells were scattered throughout the habitat; virtually no living individuals were located and he characterized the locale as "The Tortoise Killing Fields." Poaching of the tortoises occurs throughout the year but predominantly in March. Populations of the other three indigenous tortoise species were near collapse as well. I asked Behler what the likely fate for these taxa would be in a decade or two in the wild and he said "They are doomed!" It seems as though he was right.

Endangered Iguanas

The Grand Cayman Blue Iguana (*Cyclura nubila lewisi*) was described in 1940 by Chapman Grant in *The Herpetology of the Cayman Islands* and was nearly extinct at that time. The lizard formerly was widely distributed in dry habitats over most of the island but is now restricted to a few remnant populations, a consequence of the introduction of feral animals, combined with habitat destruction and development. In 2002, the population

Green Iguanas (*Iguana iguana*) have been established on Cayman Island, posing a threat to the Blue Iguana. Illustration (top left) from Seba, Albertus. 1734–1765. *Locupletissimi rerum naturalium thesauri accurata descriptio, et iconibus artificiosissimis expressio, per universam physices historiam : Opus, cui, in hoc rerum genere, nullum par exstitit / / Ex toto terrarum orbe collegit, digessit, descripsit, et depingendum curavit Albertus Seba ...*

Imprint: Amstelaedami : Apud J. Wetstenium, & Gul. Smith, & Janssonio-Waesbergios.

crashed alarmingly, dropping to only 15–25 individuals.

Frederic J. Burton, a botanist formerly with the Caymans National Trust, began developing a captive population of iguanas in the Queen Elizabeth II Botanical Gardens on Grand Cayman in the early 1990s and expanded the program dramatically since that time. In those early days, Smithsonian National Zoological Park herpetological curator Dale Marcellini was instrumental in developing the program for radio-tracking these remarkable lizards and initiating a captive management program for reintroduction. In his lively and well-written book *The Little Blue Book. A Short History of the Grand Cayman Blue Iguana* (2010, The International Reptile Conservation Foundation, San Jose, California, ISBN 087-0-578-04308-1), Burton describes the massive challenges in radio-tracking the iguanas in the dry forest habitat favored by the lizards. To evaluate the eastern site, Burton and Quentin Bloxam from the Durrell Wildlife Conservation Trust arranged a field trip, hoping that iguanas would still be found; Bloxam nearly died in the effort (see Murphy, J. B. 2007. *Herpetological History of the Zoo and Aquarium World*. Krieger Publishing Co., Malabar, Florida). Burton and many dedicated colleagues have built a breeding and head-starting facility where iguanas have been bred and returned to the wild. This book chronicles the daunting obstacles and incredible flexibility needed to design and implement an *in situ* conservation project; every zoo person should read it before starting another one.

A zoo management plan has been formulated by Tandora Grant (Studbook Keeper & Population Manager, San Diego Zoo), Rick Hudson (Species Coordinator, Fort Worth Zoo), and Jamie Ivy (Advisor, San Diego Zoo); recommendations have been outlined in the recently published *Population and Breeding Plan. Grand Cayman Blue Iguana* Cyclura lewisi—*Rock Iguana* (Cyclura) *Species Survival Plan* on 30 October 2009.

The following article by Cathy Eser (Supervisor of Menagerie) and Ken Kawata (retired General Curator) describes the major renovation of the reptile and amphibian wing of the Staten Island Zoo in New York.

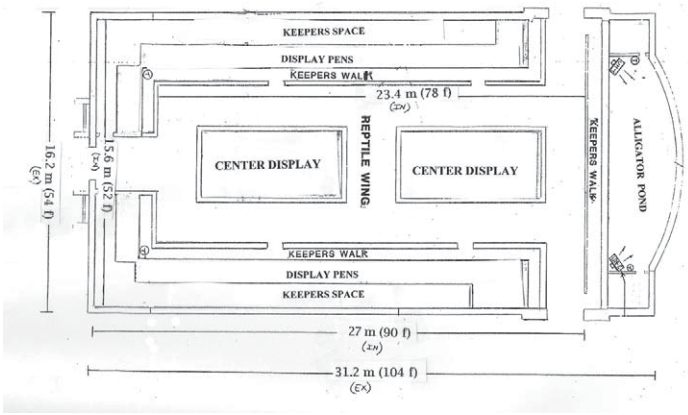
Staten Island Zoo
614 Broadway, Staten Island , New York 10310, USA

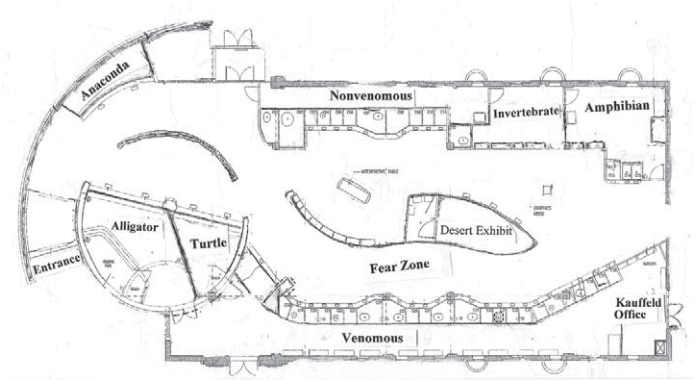
At the bottom of the Great Depression in 1936, a small zoo opened in Staten Island, New York City (hereafter SIZ). Operated by the Staten Island Zoological Society on an eight-acre (3.2 hectare) Barrett Park, it presented a unique design of a one-building zoo in the shape of a large "T," consisting of an aquarium section behind the entrance and three "wings" exhibiting mammals, birds, and reptiles, respectively. The zoo established itself as a pioneer in education and in herpetology. The zoo was intimately tied to snakes from the beginning (Kawata 2003). In particular, thanks to the vision of legendary Carl Kauffeld (1911–1974; SIZ curator of reptiles 1936–1973, director 1963–1973) the zoo was globally known for its large rattlesnake collection, exhibiting several species for the first time in the United States and internationally (Kawata 2004). In addition to the large number of articles in popular journals, Kauffeld wrote two popular books, *Snakes: The Keeper and the Kept* (Doubleday & Company, 1969), *Snakes and Snake Hunting* (Hanover House, 1957), and co-authored a third with C. H. Curran, *Snakes and Their Ways* (Harper & Brothers, 1937); together, these books inspired a generation of young herpetologists. In 1977, the wing was officially dedicated to the memory of Kauffeld. By that time the focus and emphasis of the zoo world had changed fundamentally, and the zoo's exhibit style, consisting of rows of sterile cages, had become antiquated.

It was necessary to upgrade the entire structure to meet the challenges of our time. The massive renovation began first in 1986 to face-lift the aquarium area, followed by two of the wings, ending in 1997. The City of New York furnished the funds for the project through the Department of Design and Construction (DDC). That left the reptile wing the last of the wings to be renovated. Unlike the old mammal and bird wings that gave the impression of "naked cages" of metal and concrete, the reptile exhibits had still presented an amicable atmosphere. Yet, it could not erase the appearance of the aging glass-fronted boxes. As the news of the renovation plan spread, those who "cut their teeth" in zoo herpetology in the wing expressed their fond memories of the happy, bygone days; it was not merely an exhibit facility but also a classroom that nurtured many young enthusiasts. Robert



Zappalorti, a former SIZ staff member (currently the president of Herpetological Associates, Inc., in New Jersey), was one of them.

"I guess modernizing the reptile wing means progress, which is a good thing, but on the other hand, there is so much history within the walls and cages of the old reptile wing," he noted, and wished that there were a recording device in the walls "that would have documented all the stories and conversations that were spoken over the years." (Zappalorti, pers. comm. 2005)



Early Planning Stage

A preliminary in-house review was made in 1999 to address the needs of SIZ with its unique history in education and reptiles. It was decided that, during the planning process, we should fully utilize expertise of the zoo staff who are intimately familiar with the needs of the visiting public, animal inhabitants, and daily husbandry procedures. At this juncture, an in-house committee was organized with representatives of administration, animal care, education, arts, as well as maintenance and grounds. It was the consensus of the group to invite well-experienced professionals from a prominent zoo to assist us in formulating an innovative plan. In the fall of 1999 David Jenkins and James Murphy of the Smithsonian National Zoo, Washington, D.C., were invited as consultants for concept development. The two men submitted a ten-page document in September, which established the foundation for the renovation project.

The document reminded the staff of the international recognition of SIZ generated by Carl Kauffeld. "It was certainly due to his writing skills that the reputation of the Staten Island Zoo was global," Jenkins and Murphy (1999) noted: "This history and positive reputation should be continued," and they recommended to develop Carl Kauffeld's memorial office in the new wing. Over the decades, education and exhibitry in zoos have improved markedly, they stated, but exhibitry involving reptiles and amphibians has not kept pace; it was time to develop an innovative design. As a central theme, "Use common fears as a psychological 'hook' as introduction: Confront fears and misconceptions and dispel them through science, beauty and art. Call the exhibit FEAR ZONE: A SNAKE ENCOUNTER. …An open and inviting atmosphere in the rest of the building should be light and airy." Also, "Create an exhibit of great expectations,

Floor plan of the Reptile Wing prior to the renovation as of 2005 (518 sq.m; 5.573 sq.f)

Floor plan of the Reptile Wing after the renovation as of 2007 (1,255 sq.m; 13,000 sq.f)

interaction, herpetological science," and "Develop a comfortable learning environment for both adults and children," they emphasized. In the process, they added, "Minimize excessive artificial structures and high maintenance equipment."

Once the course was established, the next step for SIZ was to select a general architectural firm. The senior staff decided to hire a local company instead of one of the out-of-state firms that specialize in zoo design; in our experience, the "specialist" designers do not necessarily meet the unique institutional needs. The zoo director was able to do this and hired the Manhattan-based architectural firm of Curtis + Ginsberg.

Design and Construction Process

Frequent progress meetings were held throughout the design and construction process with the DDC staff, architectural firm, general contractors, and members of the zoo's herpetology, maintenance, curatorial, and administrative staff. Internal meetings of the zoo staff included the graphics, education, curatorial, and herpetology departments.

The exhibit design was only one of the major aspects of the wing renovation project. There existed problems with the wear and tear of the seven-decade old facility such as a leaky ceiling, and compounding structural issues of the large auditorium located directly underneath the reptile wing. In that regard what started out as a renovation project became, in effect, a reconstruction project and general facility upgrade. The entire structure excluding the two original side walls was removed. All new HVAC, plumbing, and electrical network were installed along with a new electrical vault and generator.

General Layout

Because the location of the two side walls could not change, the remodeled wing had to retain the dimensions of the original along with an addition of a rotunda. This restriction involved creating a general layout of exhibits lining the two sides of the wing with only a portion of the center for exhibit space. (Yet, due to the added overall space we were able to increase the number of species and specimens of animals, and maintain a similar number of enclosures that we had prior to the renovation project, in addition to the new interpretive devices and exhibits.) It was decided to place inanimate interpretives on the opposite side of

live animals to avoid competing exhibits, such as live animal cages facing each other. Due to the flexibility of "jewel box" type exhibits, "It's going to be the kind of exhibit where people will notice something new every time they come," said reptile keeper Cathy Eser (Platt 2007). An additional principle was to have the front lines of the exhibits and dividing walls form a gentle curve, where possible, to counteract the rigid and artificial appearance of a straight line and boxiness of the original structure.

The Rotunda

Another change is the traffic flow of visitors. It works better now that the formal entrance starts at the opposite end of the building from where it had been originally. The beginning of the exhibit would be excavated to include a rotunda that has a prominent introduction to the new wing. The same brick types that are on the surface of the other buildings help to blend the structure with the rest of the park. All construction projects by the City of New York require a portion of the funding to be designated for the Percent for Art Program. The result is a stylized bronze sculpture of a 9.6-m (32 ft) long Reticulated Python on the wall of the rotunda, coming in and out of the brick on the exterior of the building, designed by Steve Foust, a Staten Island artist.

The entrance to the wing has glass doors hung with a "Carl F. Kauffeld Hall of Reptiles" sign. Once inside the glass doors, a visitor is greeted with the following quote from Baba Dioum: "In the end, we will conserve only what we love, we will love only what we understand, we will understand only what we are taught." Next to the quote, a mural of a vernal pool was painted with native Staten Island species. Handouts are available with a key to the wildlife within the painting. A second painting by the same muralist depicting a cladogram may be found farther in the rotunda. An illuminated wooden ceiling with etched glass panels crowns the rotunda, adding to its beauty.

This area contains three large aquatic exhibits. Here, the animals can be viewed swimming in their naturalistic environments from above and below the water's surface. A 6-m (20 ft) high pane of glass is the only barrier separating the viewer from the animal. Each exhibit has its own in-line filtration and water heating elements. Because of the massive size of the rotunda, additional heaters are used to keep the ambient temperature warm enough for the animals and visitors during the cooler months. Water features in the two largest exhibits add to the serene ambiance of the rotunda. Alligators had been an all time favorite in the old wing, and were therefore chosen as one of the species for a larger exhibit. More specifically, the Chinese Alligator, *Alligator sinensis,* is featured and is part of a cooperative captive breeding program. A sandy beach area provides a nesting ground, and a holding area separated by a planter allows animals to be separated if aggression is observed. The other large exhibit was designed for aquatic turtles, so appropriate sand depths were chosen for that beach as well. The last exhibit houses anacondas but due to the live-bearing nature of the species, does not require a sandy beach area.

The large rotunda includes three of the largest exhibits, all of which are aquatic. Note the Chinese Alligator, *Alligator sinensis* exhibit that allows the visitor to view the animals from above and below the water or when basking on the beach area. (Photo by Cathy Eser)

The Fear Zone

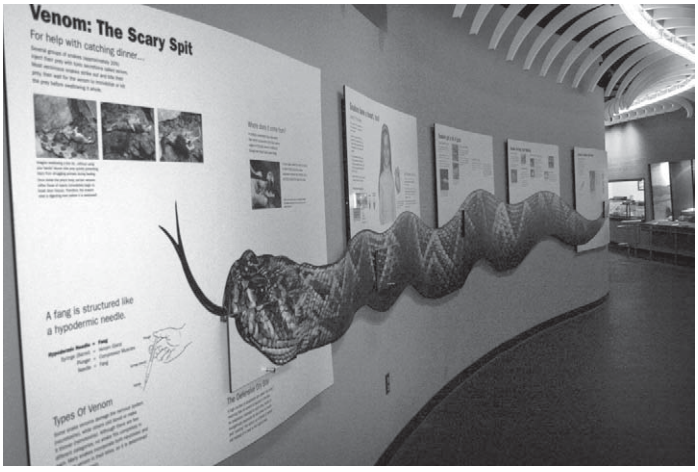
The theme of the exhibits on the south side is the Fear Zone. While increased knowledge might prevent some people from being fearful of and indifferent to the fate of snakes, there is little evidence that instruction can help the truly phobic individual overcome their animal phobias (Burghardt et al. 2007). As discussed earlier, this novel approach was incorporated in the renovation plan (see Murphy and Chiszar 1989; Burghardt et al. 2007) to dispel the public's fear of snakes through a better understanding of the animals. The exhibits contain rows of mostly small "jewel box" cages consistent with the Kauffeld tradition. The majority of the exhibits contain venomous snakes and lizards with the exception of the large python exhibit in the beginning. It was believed by management that if the majority of venomous animals were housed in the same area, it would create a safer work environment for the keepers. In addition, the antivenom refrigerator could be kept in close proximity to the emergency snakebite station. Other safety features, such as alternating shift exhibits, allow keepers to move fast-moving elapids from one exhibit to another without having to be removed from the exhibit. The total number of "jewel box" exhibits is 22.

In the original wing the lights had to be accessed from within the cage, which meant the snake had to be removed whenever a light bulb needed to be changed. In the new design, the keeper has a separate access panel that opens for safe access to electrical units. An increased number of electrical outlets has led to improved husbandry practices. We are able to create more temperature gradients between exhibits by adding more basking lights, or to increase humidity by installing humidifiers and misting systems. The service areas behind the south side have also been considerably increased in size, giving the keeper more room to handle the dangerous animals housed in this section. This was a subject that former SIZ keeper Zappalorti (pers. comm., 2005) commented on: "I'm sure that the husbandry design will be more efficient and safe in the new wing, as the old keeper's alleys were much too narrow. I can't tell you how many times I was pinned against the wall, while a large hungry python, cobra, or rattlesnake struck at me." Each exhibit was installed with an alarm system including an intercom to reach the receptionist office, and would sound over the general PA system when activated. Other husbandry conveniences are permanent fiberglass pools and

The Fear Zone area begins with a giant snakes exhibit and continues with 22 "jewel box" exhibits containing venomous snakes and lizards. The push button interactive snake skull may also be seen in this photograph. (Photo by Cathy Eser)

radiant heat pads in alternating exhibits.

At the end of the Fear Zone a Carl Kauffeld memorial office was built. Historical artifacts such as hand-made tools including snake hooks, rippers, and scoops are displayed. His original desk, letter opener, documents, and art work were donated by various SIZ alumni or retrieved from other parts in the zoo and placed in the office. This is also an area to exhibit some of the smaller captive-bred animals in small tanks that would not be seen in a large exhibit. This office can be seen from inside of the wing as well as from the hallway that leads to other wings of the zoo.



The graphics and interactive displays for the Fear Zone are numerous. To alert visitors that they are entering the area, there is a floor pad that activates the sound of a hissing snake when stepped on. Visitors are greeted with an illuminated snake skeleton that is suspended from the ceiling and runs the entire length of the Fear Zone. There is also a beautiful mosaic and panel showing cultural artwork of snakes. Next to the large snake exhibit, there is a functional replica of a viperid snake skull, activated by a push button. The exhibit was built by Peeling's Productions Inc. in Pennsylvania. There is also an informative panel that describes the methods by which snakes feed.

Across from the animal exhibits is a 7.5-m (25-ft) long Eastern Diamondback Rattlesnake graphic that contains various flip-up panels to allow the visitor to see inside of the snake. Some of these panels are activated when opened to make sounds, such as a snake's heartbeat and a rattlesnake rattle. Other flip-up panels show diagrams of the venom gland, heart, and a radiograph of a food item in the stomach. Many of the photographs were donated by SIZ alumni or taken by SIZ staff. Other flip-up panels include graphics located along the railing in front of the exhibits. Some of the topics covered are how many humans are harmed by automobiles or by non-reptilian venomous animals than are harmed by snakes. For example, one flip-up asks, "Still think snakes are the most dangerous animals around? Out of these, what is your guess?" There is a picture of a cobra, conesnail, and platypus. The answer is the conesnail.

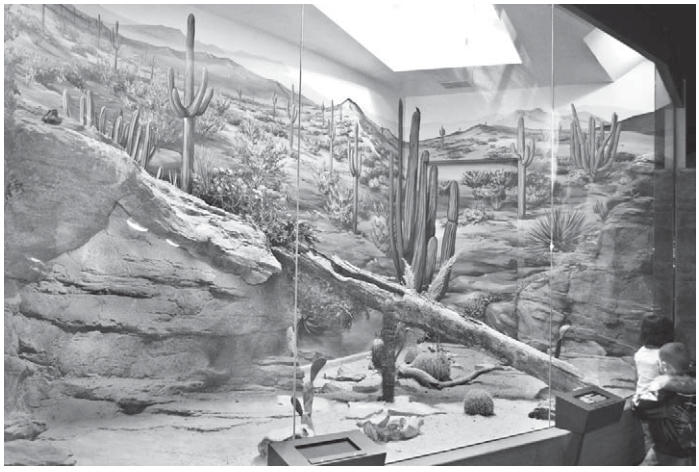
Amphibian Area

Along the north side of the wing, an attempt was made to bring a more modern approach to the exhibits and types of species exhibited. Many people know of the global amphibian crisis, yet amphibians have historically been poorly represented in zoos. This is partly because they generally require more controlled environmental conditions than was made available in the old-styled exhibits. For this reason, a large area was allocated for an air-conditioned room with sufficient space for aquatic life support systems, water purification systems, food cultures and various other products needed for their care.

Two of the exhibits are large fish tanks that can house aquatic amphibians. The two species exhibited are Mexican Axolotls (*Ambystoma mexicanum*) and Mudpuppies (*Necturus maculosus*). The background of the tanks is covered to create a naturalistic appearance, and because of the delicate nature of amphibians we hired Petra Works, Inc. (New Jersey), a company that specializes in rockwork of amphibian exhibits. The filters in the tanks are polybead filters and a chiller cools the mudpuppy tank. A reverse osmosis unit feeds into a large reservoir and is hooked to a

A 7.5 m (25-foot) long Eastern Diamondback Rattlesnake graphic runs the entire length of the Fear Zone educating the visitor about snake anatomy, physiology and behavior. (Photo by Cathy Eser)

The amphibian and invertebrate exhibits add a diversity of new taxa that were not previously represented by the SIZ. The exhibits are modern in design and style. (Photo by Cathy Eser)



pump and hose for water changes. Also, the water can be easily reconstituted with commercial products.

Two other exhibits are tall "jewel box" style that house various frog species. They are retrofitted with artificial rockwork that contains planters, so the exhibit could be lushly planted and the animals could be seen utilizing the various heights of the exhibit. They also have acrylic inserts with murals painted on them. The temperature and humidity can be adjusted by addition of lighting or humidifiers.

The last two exhibits in the amphibian room are custom-made modular units that were ordered from Waterdog Inc. (California). They were built with various ports so that water features could be added and with side and top access panels. In one of the exhibits is a Ridge-nosed Rattlesnake, *Crotalus willardi*, a mountain species that fares better in a cooler exhibit. This exhibit has a carved desert rockwork background done by Petraworks Inc. The second modular exhibit has a vernal pool background and holds Gray Tree-Frogs, *Hyla versicolor,* and Jefferson Salamanders, *Ambystoma jeffersonianum*. The design of the amphibian area and the adjacent invertebrate area was basically redone in the middle of the construction process due to the relative small size of the originally planned exhibits and the lack of graphics. The new plan incorporates a habitat and adaptations theme to coincide with the exhibit next to it. The topics that are covered are animals that live on mountains, in vernal pools, in trees, or underground. There is also a panel describing how invertebrates are responsible for creating certain types of habitat. Each panel also contains a conservation message called "Conservation Connection."

Invertebrate and Desert Exhibits

One of the objectives of the new exhibit was to have the potential to exhibit a broad range of species. That meant an area that adhered to containment specifications by the U.S. Department of Agriculture so that invertebrates could also be exhibited. The specifications included a second set of doors, separate air handlers, and responsible ways to decontaminate waste from the exhibits. Habitat graphics are matched with the animals on exhibit. Next to the graphic about fossorial animals, there are two exhibits that are 151-liter (40-gallon) fish tanks with plumbing hooked up to filters and chillers to house salamanders. These animals spend a majority of their lives underground near fresh springs. The exhibit that accompanies the graphic about arboreal animals houses Australian Walking Sticks, *Extatasoma tiaratum*.

There is a large center exhibit representing the Sonoran Desert fauna with naturalistic rockwork containing radiant heat and ultraviolet basking light bulbs. (Photo by Cathy Eser)

The keepers wanted to exhibit some species of social insects, which are generally very active and therefore visually interesting. We chose the Honey-Pot Ant, *Myrmecocystus mimicus*. This exhibit was designed and built by Work As Play Inc. (Arizona). The transport of the unit and the animals was a fun adventure for the keepers who drove them across the country from Arizona. The animals were the most delicate among the species housed in the wing, and eventually succumbed due to an infestation of mites that attacked the colony. They were not replaced and the exhibit now contains a Texas Patch-nosed Snake, *Salvadora grahamiae.*

The last exhibit in the invertebrate area housed another species of social insect, Pacific Dampwood Termites, *Zootermopsis angusticollis*. They also proved to be challenging to exhibit due to their fossorial nature.

A large, terrestrial exhibit features the Sonoran Desert, an arid region unfamiliar to the public in the eastern seaboard states. Due to the high ultraviolet light requirement of diurnal desert lizards, specific light bulbs are used in an outcropping of artificial rockwork that enables the animals to bask. Radiant heat is run under specific parts of the exhibit. The mural of the exhibit, depicting the arid habitat, was painted by the artist Amy Bartlett, and it represents the largest of her four mural projects in the wing.

Non-venomous Animals and Interpretive Area

There are still more reptile taxa on exhibit in addition to the snake-themed Fear Zone and the amphibian area. The turtles and lizards are represented in the remaining 12 exhibits of the north side of the wing. Some of the species on exhibit are Blue Tree Monitors, *Varanus macraei,* Wood Turtles *Glyptemys insculpta*, New Caledonia Gecko, *Rhacodactylus leachianus* and a Rhinoceros Iguana, *Cyclura cornuta.*

Across from those exhibits is an interpretive area where zoo volunteers can show live animals to the public. In part, this is a continuation of the Fear Zone where a visitor may encounter a volunteer holding a live snake. There is a table that volunteers use to set animals on that has a tabletop that is an educational tool and has footprints of different reptiles embedded in the resin. Inside of the table lies the shell of a Galapagos tortoise by the name of "Jalopy," who was well known in the 1980s for having the first recorded case of a malignant fibro-sarcoma in a reptile. Four display cases line the back of the interpretive area. The topics covered are shell differences, reptile and amphibian skulls and bones, radiotelemetry devices, and an archaeological dig about when early reptiles and amphibians began to evolve. A video monitor is also hung in this area.

A Timeline

SIZ has enjoyed a strong community support from its very beginning. Reflecting this tradition, what made the renovation project possible was the continuous efforts by elected officials, such as City Councilman (currently U.S. Congressman) Michael McMahon, for the allocation of city funds. However, due to

the unforeseen financial situation of the city, the availability of the funds materialized later than expected. In order to mark the beginning of the project, a groundbreaking ceremony was held on 11 March 2005. At that time there were 45 exhibits in the original wing with 83 species of reptiles and 16 species of amphibians on the inventory, yet only four amphibian species were on exhibit. The large American alligators had been moved out by that time. The non-venomous reptiles were moved out of the wing on 14 March 2005 into holdings in the Animal Hospital, and the venomous reptiles were moved out of the wing on 23 March 2005 into the Animal Hospital as well. This left the Animal Hospital holding space filled to maximum capacity, with little space to quarantine new animals. Thus the acquisition and quarantine of new specimens had to be a carefully coordinated procedure over the next two years for the new exhibit opening. The last day that the wing was opened to the public was 27 March 2005. Demolition of the wing was started three days later.

The Carl F. Kauffeld House of Reptiles was opened by Michael Bloomberg, the Mayor of New York on 18 April 2007. At that date there were 127 reptile specimens in 66 species, and 97 amphibian specimens in 22 species with 12 of those species on exhibit. The $15 million project expanded the size of the wing to 1,255 square meters (13,000 square feet) which enabled us to increase the number of animals in the new wing.

After a "sneak preview" of the renovated wing, a local reporter observed that the refurbished wing "represents a renewal of Kauffeld's project and the institution's larger missions" and "Each section of the wing represents a feat of architecture and design -- a collaborative effort on the part of engineers, builders, artists, keepers and administrators—to create functional, educational and aesthetic exhibits that balance the needs of animals, Zoo workers and visitors." (Platt 2007) Likewise, zoo director John Caltabiano attributed the reconstruction to teamwork among city agencies, designers and zoo staff (Caltabiano et al. 2007). In terms of husbandry, 85% to 90% of the requirements suggested by the animal care staff, such as size of the service area, the microclimate control system, staff safety measures and utility needs materialized in the behind-the-scenes area.

Acknowledgments.—Without the concerted efforts by many individuals the Reptile Wing renovation project would not have been a successful endeavor. We would like to express our appreciation to Vincent Gattullo and John Caltabiano, the former directors of the Staten Island Zoo, for their support. Special thanks go to Amar Malla and Charles Orlando of the City of New York Department of Design and Construction; Darby Curtis, Partner, Curtis + Ginsberg LLP, Karen Mohlenbrok from Hill International, and former and current SIZ staff members (in alphabetical order) Frank Indiviglio, Bob Kurtz, Peter Laline, Matt Lanier, Jim McNiesh, Ellen Palm, Lisa Salmose, and Harry Strano.

A Comparison of Carapace-Mounted and Body Cavity Implanted, Thermally-Sensitive Radio Transmitters with Implications for Thermoregulation in Free-Ranging Midland Painted Turtles (*Chrysemys picta marginata*)

JOHN W. ROWE*

In ectotherms, the influence of environmental temperature (T_e) on body temperature (T_b), and resulting physiological processes (Peterson et al. 1993), makes thermal ecology essential to understanding energy acquisition and life histories (Congdon 1989). Investment in behavioral and physiological thermoregulation ranges from little or none (thermoconformity) to precise thermoregulation around a thermoregulatory set point (Christian et al. 2006; Hertz et al. 1993). Ultimately, the investment in thermoregulation is determined by the benefits of attaining T_b that is optimal for various physiological processes weighed against the costs of failing to invest in activities such as foraging or mate location (Blouin-Demers and Weatherhead 2001; Huey and Slatkin 1976). Freshwater turtles are ectotherms that thermoregulate within limits set by temporal variations in aquatic and atmospheric thermal environments (Spotila et al. 1990). In Painted Turtles (*Chrysemys picta*), for example, daily T_b cycling apparently results from behavioral and physiological modifications (Rowe and Dalgarn 2009). Edwards and Blouin-Demers (2007) concluded that field active *C. picta* are capable of at least moderate thermoregulation.

Because of the dynamic, cyclic nature of T_b in ectotherms, the study of T_b variation requires fairly constant acquisition of data points. In freshwater turtles, T_b variation is studied by surgical implantation of thermally-sensitive radio transmitters, or surface-mounted radio transmitters with thermal probes, coupled with remote data logging (Brown et al. 1990; Manning and Grigg 1997; Rowe and Dalgarn 2009), or by the surgical implantation of thermally-sensitive data loggers (Edwards and Blouin-Demers

2007; Plummer et al. 2005; Sajwaj and Lang 2000). However, surgical implantation of thermally-sensitive devices can require extended post-surgical recovery periods and runs the risk of adverse effects, particularly when individuals are relatively small. Alternatively, thermally-sensitive radio transmitters or data loggers can be mounted on the carapace and shell temperature (T_s) used as a proxy for T_b (Grayson and Dorcas 2004; Litzgus and Brooks 2000). However, T_s values presumably reflect not only thermal conduction from the shell, but also the influences of thermal radiation and water temperature directly on the radio transmitter. Therefore, T_s should reflect the temperatures of thermal patches selected by the turtle, including basking events (Grayson and Dorcas 2004; Plummer et al. 2005; Sajwaj and Lang 2000). Under variable controlled conditions, Grayson and Dorcas (2004) found that cloacal temperature of the relatively small-bodied Painted Turtle (*Chrysemys picta*) deviated from T_s by less than 1ºC and so T_s may be an acceptable estimator of T_b. In *C. picta* under field conditions, Edwards and Blouin-Demers (2007) found significant deviations of midday T_b from T_s under variable environmental temperatures. Similarly, Dubois et al. (2009) reported correlated midday T_b and T_s of free-ranging Wood Turtles (*Glyptemys insculpta*) but with T_s distributions that deviated from, and generally exceeded, T_b distributions. Apparently, thermal inertia associated with body mass buffers temperature changes of body cavity-implanted radio transmitters relative to carapace-mounted radio transmitters that are directly exposed to solar radiation and water and air temperatures. It could then be predicted that T_s values would be more extreme and variable than T_b values and, depending on the size of the turtle, the apparent initiation and duration of a thermoregulatory event (e.g. basking) could vary between T_b and T_s data sets.

We studied T_b and T_s variation in six free-ranging *Chrysemys picta marginata* at Miller's Marsh on Beaver Island, Michigan, using both body cavity-implanted and carapace-mounted radio transmitters. Miller's Marsh is a small north-temperate marsh system in northern Michigan that is subject to daily and seasonal fluctuations in water temperatures (Rowe 2003; Rowe and Dalgarn 2009). The two main goals of our study were the determination of: 1) how closely diurnal thermal events (e.g. basking) of the thermal profile are coupled temporally as measured as T_b vs. T_s, and 2) how, or if, T_b and T_s depart in value over time. To determine if the timing and durations of readily identifiable thermal events coincided over time as measured as T_b vs. T_s, we compared the initiation, termination, and duration of the pre-midday temperature decline and the midday temperature spike for T_b and T_s data. The pre-midday spike decline may represent movement through cool water, some physiological adjustment (Rowe and Dalgarn 2009), or evaporative cooling (Case 1972) at the initiation of some basking event. The midday spike may be a very important thermoregulatory event as it presumably represents aerial or aquatic basking (Grayson and Dorcas 2004; Plummer et al. 2005; Rowe and Dalgarn 2009). We expected that during the early morning hours, when solar energy would be minimal, mean hourly T_b and T_s values would closely coincide. During the late morning and afternoon, when available solar energy would be maximal, we expected that the initiations of the pre-midday spike temperature decline and the midday temperature spike would occur earlier in T_s data than in the T_b data. We had no *a priori* expectation for the durations of the pre-midday spike decline and midday spike. Due to thermal inertia associated with body mass, we anticipated that midday T_s values would exceed T_b values (Dubois et al. 2009; Edwards and Blouin-Demers 2007) and that T_s values would be more variable and extreme than T_b values.

Materials and methods.—We collected turtles in baited funnel traps or by hand beginning in early May 2006. We obtained carapace length (CL) and body mass (BM) and uniquely marked each individual. Eight individual turtles (4 F and 4 M) received both carapace-mounted and surgically implanted thermally sensitive radio transmitters (Advanced Telemetry Systems) that were calibrated together in a water bath (1–45°C). Radio transmitters (2.5 g) with whip antennae were adhered to the dorsal margins of the carapace using epoxy. Radio transmitters (2.8 g) with a coiled antenna were surgically implanted in the body cavities anterior to the left hind limb (Rowe and Dalgarn 2009). Turtles were allowed to recover for 4–5 days before returning them to the marsh. Of the original eight radio-tagged turtles, four females (mean CL ± SE = 151.5 ± 2.53 mm, min.–max. = 144–155 mm; mean BM = 411.3 ± 19.19 g, 355–440 g) and two males (mean CL = 136.5 ± 6.50 mm, 130–140 mm; mean BM = 276.0 ± 36.00 g, 310–240 g) were monitored throughout the summer months. One male moved beyond detection of our data-logging radio receiver early in the summer and the internal transmitter of another male failed soon after its release.

At a central location in the marsh, we placed a radio receiver (TR5, Telonics. Inc.) that was equipped with an omnidirectional antenna. We programmed the radio receiver to record pulse intervals (duration of time between pulses; mSec) for each turtle's radio transmitter every 15 min for a maximum of 96 observations per individual per day. Turtles were monitored between 10 May and 14 August for a total of 294 individual turtle observation days. We converted pulse interval values to T_b or T_s values for each individual using polynomial regression equations ($R^2 > 0.99$).

To determine whether T_b and T_s values obtained during readily identifiable thermal events coincided temporally, we manually recorded times (to the nearest 15 min, 0000 h = 0 min to 2345 h = 1425 min) at the initiation of the pre-midday spike temperature decline and of the midday temperature spike for each individual on each day. The average differences in time (min) between the initiation of basking for T_b and T_s and between the termination of basking for T_b and T_s were determined per individual and differences tested by Wilcoxon signed-rank tests.

We tested for differences in value between T_b and T_s overall and temporally in two ways. First, we examined residuals of T_b on T_s as plotted on T_s, as a predictor of T_b, and on each 15 min interval throughout the day. For the regression analysis, we determined mean values for each 15 min interval and then averaged them across individuals for both T_b and T_s. If T_s is a reasonable predictor of T_b, then residual plots should show an even distribution over values of T_s and over the course of the day. Second, we analyzed the difference between hourly T_b and T_s (T_b-T_s) by ANOVA with transmitter type (body cavity-implanted or carapace-mounted), hour-of-day (0000–2300 h), radio transmitter type x hour-of-day terms included as fixed effects. Hourly T_b-T_s values were averaged across 15 min intervals per hour (0000–0045 h, 0100–

0145 h, etc,) per individual, and then hourly values were averaged per individual over the entire study period. To assess relative variability of T_b vs. T_s, we calculated mean hourly coefficients of variation (CV x 100) for each variable (CV T_b and CV T_s) and for each individual over the summer and used ANOVA as described previously for analysis of T_b-T_s. Small sample size for males precluded the use of sex as a main effect. In both ANOVA models, we included turtle identification (ID) number and sex as random variables to account for autocorrelation and potential inter-sexual differences respectively. *Post-hoc* comparisons were made using least square means (LS means) multiple t-tests. Test statistics were considered significant at or below alpha = 0.05 unless otherwise specified.

Results.—For individual turtles, both T_s and T_b recorded at 15 min intervals showed diel cycling that included monotonic declines, pre-midday spike declines, midday spikes and oscillations, and late evening and early morning monotonic declines (Fig. 1A). Of the 190 total turtle observation days for which 96 observations per individual per day were obtained, well-defined midday spikes were observed on 70.0%, pre-midday spike declines occurred on 24.7%, and no discernable temperature cycling was observed on 5.3%.

The timing and durations of the pre-midday temperature spike decline and the midday temperature spike did not vary between data recorded by body cavity-implanted and carapace-mounted radio transmitters. For both T_b and T_s, pre-midday spike declines were initiated between 0500 and 1000 h (middle 50%: 0615–0815 h) and had durations of 118 ± 14.4 min (75–165 min, N = 6) and 122.2 ± 17.34 min (90–178 min, N = 6) respectively. Midday

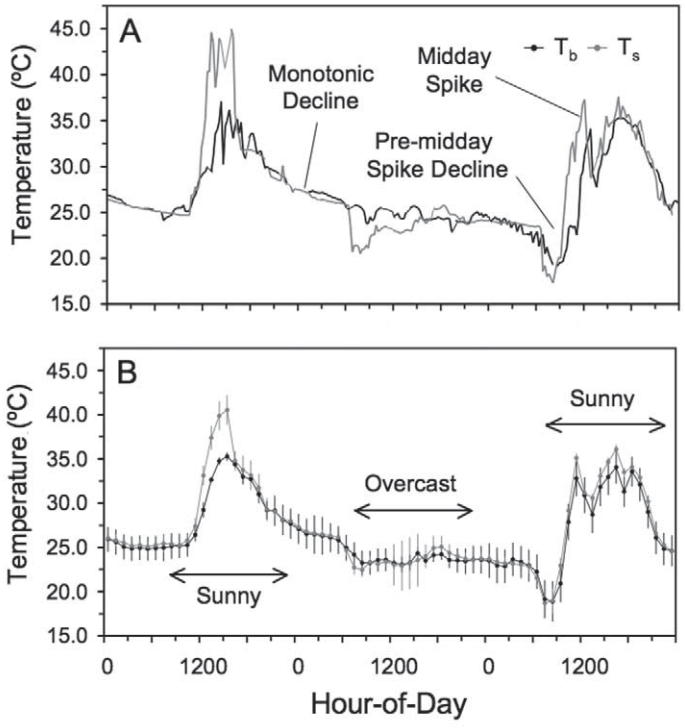

FIG. 1. A) Body temperature (T_b) and carapace surface temperature (T_s) measured in a single *Chrysemys picta marginata*, and B) mean T_b and T_s ± 1SE (vertical lines) measured at 15 min intervals in six individual *C. picta marginata* at Miller's Marsh, under variable weather conditions between 1 and 3 August, 2006.

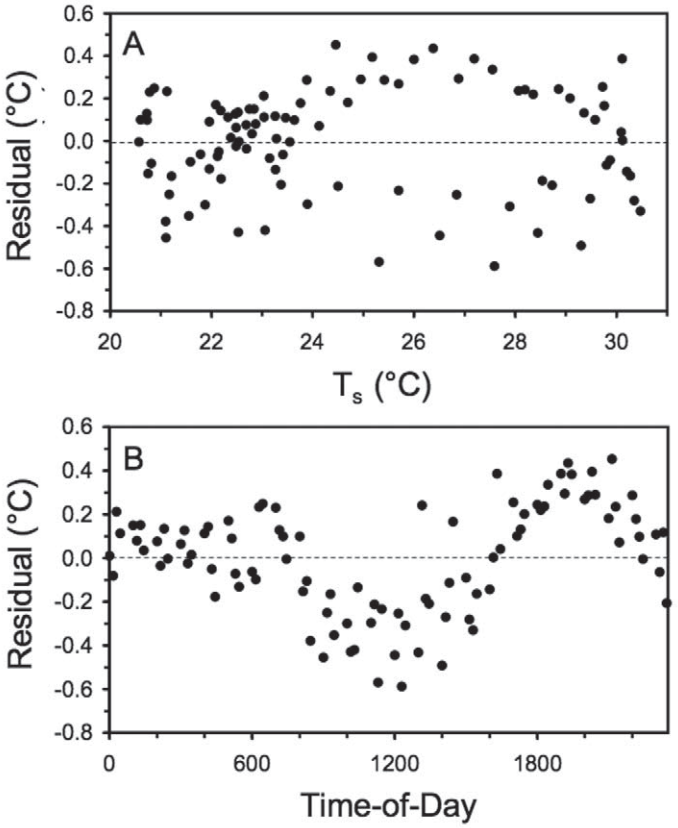

FIG. 2. Residual values from the regression of mean T_b on T_s (averaged per individual) plotted on A) T_s, and B) time-of-day at 15 min intervals in six *Chrysemys picta marginata*.

spikes were initiated between 0745 and 1530 h (middle 50%: 0945–1130 h for T_s and 1000–1145 h for T_b) and maximum values occurred between 0930 and 1815 h (middle 50% 1215–1430 h for T_s and 1230–1430 h for T_b). Mean durations of basking (time between initiation and peak of the mid-day spike) were 152.7 ± 9.50 min (118–181 min, N = 6) for T_b and 149.8 ± 9.30 min (124–178 min) for T_s. The initiations of the pre-midday spike decline and midday spike of T_s occurred slightly before those of T_b (8.3 ± 6.80 min, 0–16.4 min, N = 6, and 5.1 ± 4.11 in, 1.0–10.4 min, N = 6, respectively). However, Wilcoxon signed-rank tests of the timing of initiation and termination and of the durations of the pre-midday spike decline and midday spikes were not significant ($P > 0.05$ in all comparisons).

On sunny days, T_s increased more rapidly and attained higher maximal values, by as much as 10°C, than did T_b but such differences were not as pronounced on overcast and cool days (Fig. 1A). Averaged per individual, T_s and T_b values appeared largely concordant during most of the day but T_s exceeded T_b during the afternoon hours on sunny days (Fig. 1B). Mean minimum T_s and T_b values, averaged across individuals throughout the summer (N = 6), were roughly similar (mean minimum T_s = 11.8 ± 1.67°C versus mean minimum T_b = 12.5 ± 1.05°C) but mean maximum values were more dissimilar (mean maximum T_s = 44.6 ± 1.87°C vs. mean maximum T_b = 37.8 ± 0.24°C).

Overall, and on a diel basis, mean hourly T_s tended to exceed, and was more variable than, mean hourly T_b and the magnitude of difference was greatest during the afternoon. Averaged across all

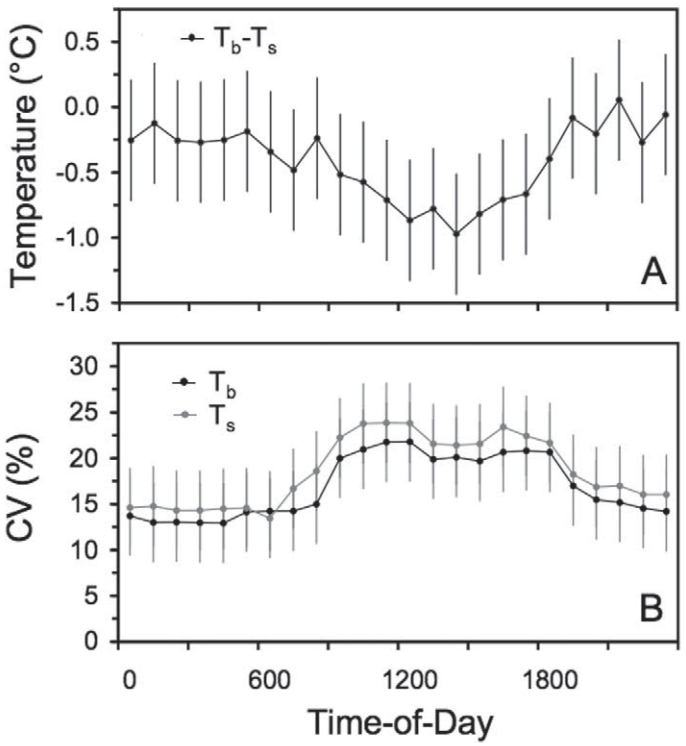

FIG. 3. A) LS mean (± 1 SE) hourly difference between T_s and T_b (T_s-T_b), and B) mean hourly coefficients of variation (CV) in six *Chrysemys picta marginata* at Miller's Marsh, 2006.

individuals at 15 min intervals, T_b regressed on T_s was significant and linear ($T_b = 1.60 + 0.94T_s$, $F_{1,94} = 13{,}687.7$, $P < 0.00001$, $R^2 = 0.99$). A residual plot indicated that observed T_b values tended to deviate from predicted T_b values as T_s values increased (Fig. 2A). Residuals plotted over the course of the day indicated that T_b values tended to be lower than predicted T_b values during the afternoon and exceeded predicted T_b values during early morning and late evening (Fig. 2B). In the ANOVA of the difference between T_b and T_s (T_b-T_s), hour-of-day as the main effect was significant ($F_{23,120} = 2.5$, $P = 0.0007$, $R^2 = 0.87$). The magnitude of difference was greatest between 1000–1700 h, lowest and near 0°C between 1900–2100 h, and intermediate during the early morning and late evening hours (Fig. 3A). Temperature variability, as measured by CV T_b and CV T_s, varied as a function of radio transmitter type ($F_{1,240} = 15.6$, $P = 0.0001$, $R^2 = 0.97$) and hour-of-day ($F_{23,240} = 157.7$, $P < 0.0001$), but the radio transmitter type x hour-of-day term was not significant ($F_{23,240} = 0.3$, $P > 0.05$). Overall, LS mean CV T_s (16.9 ± 5.67) was significantly more variable than LS mean CV T_b (15.3 ± 5.67). *Post hoc* comparisons indicated that, for both CV T_b and CV T_s, variability was relatively low between 0000–0600 h, increased sharply after 0600 h, attained maximal values between 1000–1800 h, and declined gradually during the late evening hours (Fig. 3B). Nonsignificant interaction terms in both ANOVA models indicated that the magnitude of differences between, and variability in, T_b and T_s remained approximately constant throughout the day (Fig 3A–B).

Discussion.—We tested whether T_s values, as recorded by carapace-mounted radio transmitters, accurately estimated T_b values that were recorded using body-cavity implanted radio transmitters in *Chrysemys picta*. On a daily basis, data from both types of transmitters oscillated in a similar way. As we expected, T_b and T_s values were similar during the early morning hours, when aquatic activity is reduced and when turtles were presumably submerged (Rowe 2003). That we detected pre-midday spike declines on the surface of the carapace in T_s data, which averaged over 2.5 h in duration, indicates either movement through cool water before basking or perhaps evaporative cooling at the initiation of aerial basking (Case 1972). Since evaporative cooling would be expected to occur each time that aerial basking was initiated, we suspect that the former explanation accounts for the pre-midday spike T_b decline. If, indeed, the midday spike represents an aerial basking event (Edwards and Blouin-Demers 2007; Plummer et al. 2005; Sajwaj and Lang 2000), the use of T_s as a proxy for T_b might be valid for determining the frequency, timing, and duration of basking events that occur during a specified time period (Grayson and Dorcas 2004). However, we suspect that with relatively large sample size and shorter time intervals between the acquisition of successive data points (<15 min), differences between T_b and T_s in the initiation of basking events could be detected.

We conclude that body cavity-implanted thermal data recording devices would be preferred for the estimation of T_b and the study of thermoregulatory precision in most species. Our T_s values were higher and more variable than T_b values, particularly when solar radiation levels were relatively high. Similarly, Edwards and Blouin-Demers (2007) found that when T_b values were relatively high, and exceeded instantaneously recorded T_s values, with the converse occurring when T_b values were relatively low. Because we detected T_s values greater than the thermal critical maximum for *Chrysemys picta* (41.5–42.3°C, Brattstrom 1965; Ernst 1972), carapace-mounted thermal data recording devices would not accurately estimate T_b at relatively high T_e. Yet, we found that mean T_b-T_s was maximal and less than 1°C during the afternoon hours and T_b and T_s values in *C. picta marginata* were far more concordant than in the relatively large-bodied *Emydoidea blandingii* (Sajwaj and Lang 2000). Therefore, T_s values might adequately estimate T_b in relatively small-bodied freshwater turtles or in juveniles whose relatively small bodies would respond more quickly to changes T_e than would those of adults.

Acknowledgments.—We thank J. C. Gillingham and Central Michigan University's Biological Station for laboratory space, transportation, and logistic support. Funding was provided by the Costable Fund, Biology Department, and Faculty Small Grants of Alma College. Turtles were collected under a Scientific and Cultural Collecting Permit (#SC1185) issued by the Michigan Department of Natural Resources. All animals were handled in accordance with the Alma College IACUC standards and under the Nation Institutes of Health Assurance 4162. Surgical assistance was provided by D. Breen.

Geographic Variation in Philippine Mimicry System: Hypothesized Widespread Coral Snake (*Hemibungarus calligaster*) Mimicry by Lepidopteran Larvae (*Bracca* sp.) on Luzon Island, Philippines

CAMERON D. SILER*

**Corresponding author; e-mail: camsiler@ku.edu*

Aposematic Batesian mimicry of elapine coral snakes has been widely documented, with the most well-known and highly referenced phenomena occurring between the highly venomous coral snakes of the New World (*Leptomicrurus*, *Micruroides*, and *Micrurus*) and a number of relatively harmless colubrine snakes (e.g., *Lampropeltis triangulum* ssp.; Brodie 1993; Greene and McDiarmid 1981; Greene and McDiarmid 2005). Less common are similar cases of mimicry of the Old World coral snakes (*Hemibungarus*, *Calliophis*). A number of experimental studies have documented apparent increased fitness of relatively harmless species that, even to varying degrees, mimic the aposematic coloration of the highly venomous model species (Brodie 1993; Brodie and Janzen 1995). In such studies, correlations between the model species' abundance and the quality of mimicry indicate an underlying geographic variation in a given mimic's level of similarity to the model species (Harper and Pfennig 2007). Although this system of mimicry has been documented and studied with colubrine mimics, general Aposematic Batesian mimicry systems involving arthropods are much more common (Greene and McDiarmid 1981; Brodie and Moore 1995).

Brown (2006) reported a potential case of mimicry involving the larvae of a species of lepidopteran in the genus *Bracca* and the Philippine coral snake *Hemibungarus calligaster calligaster*. The larva possessed banding and color patterns highly similar to the coral snake where they are sympatric on two distinct mountain ranges of the Bicol Peninsula of southeast Luzon Island, Philippines (Fig. 1). Upon closer inspection of the *Hemibungarus* from the collection of Brown (2006), it is clear that the Bicol Peninsula subspecies is morphologically most similar to *H. c. mcclungi*, formerly believed to be endemic to Polillo Island (Leviton 1963). Brown (2006) questioned whether this example of mimicry was widespread across the Philippines, and whether morphological differences in banding patterns among subspecies of Philippine *H. calligaster* were mirrored in changes in banding pattern of sympatric lepidopteran larvae. In this note, we question the hypothesis of a widespread case of mimicry, report on additional observations of the sympatric association of *Bracca* and *Hemibungarus*, and compare banding and color patterns between two subspecies of *Hemibungarus* and the sympatric lepidopteran from Luzon Island, Philippines.

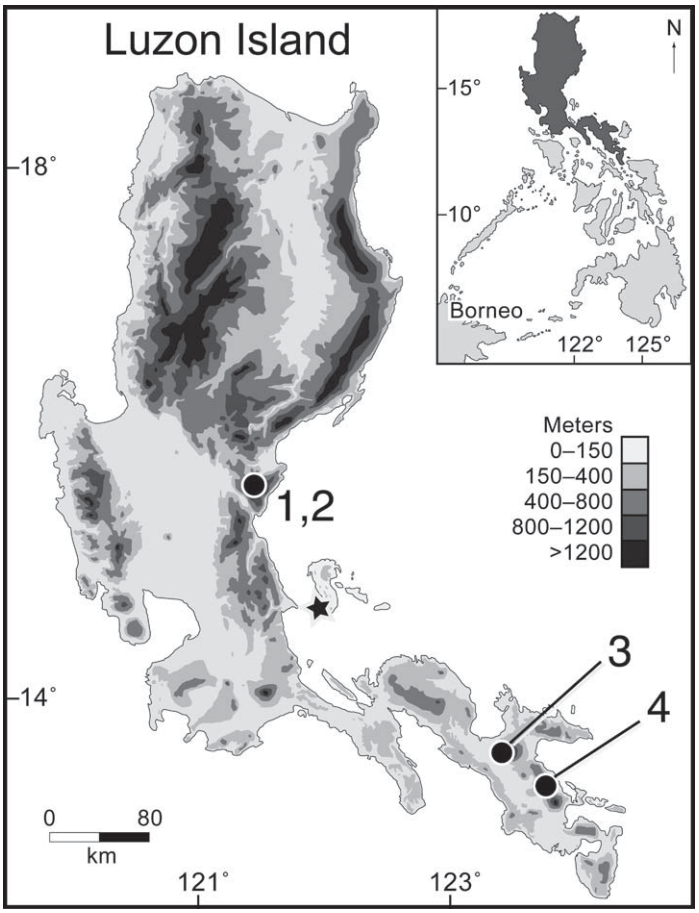

FIG. 1. Localities of observed occurrences of *Hemibungarus calligaster* cf. *mcclungi*, *H. c. calligaster*, *H. c. mcclungi*, and the lepidopteran larvae (genus *Bracca*) on Luzon Island, Philippines. Localities 1 and 2 represent sampling localities from this study, 3 and 4 represent sampling localities from Brown (2006), and the type locality of *H. c. mcclungi* marked with a star. The inset shows the location of Luzon Island (colored black) within the Philippines.

Methods.—In June 2009 we conducted herpetological field surveys at two sites in Aurora Province, Luzon Island: Site 1, mid-elevation forest of Barangay Lipimiental, Municipality of San Luis (15.65366°N, 121.50734°E; WGS 84; Fig. 1); Site 2, mid-elevation forest of Mt. Dayap, Aurora Memorial National Park, local area "Siete," Barangay Villa Aurora, Municipality of Maria Aurora (15.680°N, 121.336°E; WGS 84; Fig. 1). Specimens were deposited in the Philippine National Museum and the University of Kansas Natural History Museum. We measured relative lengths of the color bands of *Bracca* larvae and *Hemibungarus* coral snakes from alcohol-preserved specimens using digital calipers to the nearest 0.1 mm and follow Brown (2006). Bands were measured from their anterior to posterior edges, with all measurements scored by LJW. The coral snake was keyed to species with reference to Leviton (1963), and genus-level identification of the lepidopteran larvae was provided by Brown (2006) and Holloway (1991, 1993).

Results and Discussion.—At Site 1, one individual of the coral snake, *H. c. calligaster* (KU 323337), and two *Bracca* sp. larvae were observed (one collected, deposited in the KU teaching collection). Both *Bracca* sp. larvae were observed suspended 0.5 meter above the ground from a thread of silk. The coral snake

TABLE 1. Summary of body and banding pattern measurements in *Hemibungarus calligaster calligaster* and *H. c.* cf. *mcclungi*, and the associated *Bracca* sp. from this study and Brown (2006). Sample size for each species and study are included for reference, and all measurements given as the range followed by mean ± standard deviation.

	Hemibungarus c. cf. *mcclungi* (N = 4; Brown 2006)	*Hemibungarus c. calligaster* (N = 2; this study)	*Bracca* sp. (N = 5; Brown 2006)	*Bracca* sp. (N = 1; this study)
Total body length	479–510 (498.5 ± 14.5)	525, 554	71–92 (78.8 ± 8.1)	56.2
Body width at midbody	9.0–17.0 (14.0 ± 0.2)	9.0, 9.1	7.0–11.0 (9.0 ± 0.2)	6
White annuli width	9.0–13.0 (11.0 ± 0.2)	2.8, 2.9	7.0–11.0 (9.0 ± 0.2)	1.5
Black band width	13.1–18.2 (15.8 ± 0.9)	6.6, 6.9	6.0–10.3 (7.5 ± 0.2)	5.9
Red band width	13.8–17.0 (15.8 ± 1.7)	10.7, 10.8	7.4–11.5 (9.2 ± 1.3)	5.1

was found under rocks near a stream. A second coral snake (KU 323337) was collected at Site 2 under rocks near a stream. No *Bracca* sp. larvae were observed at Site 2. When disturbed, both snake and caterpillar exhibited jerky movements, including body twisting and flipping, similar to the observations of Brown (2006).

Both subspecies of coral snake and the lepidopteran larvae possess brightly colored banding patterns (Fig. 2), as observed by Brown (2006). However, the order of colored bands and location of white annuli in the *Bracca* specimens most closely matches those of *H. c.* cf. *mcclungi* in the Bicol Peninsula of Luzon Island (Fig. 2B). In *H. c.* cf. *mcclungi*, the white annuli are clearly defined and divide the black bands into a pattern of black band-white annuli-black band. This pattern is bordered by red bands, and closely resembles the color and banding pattern of the lepidopteran larvae in the Bicol Peninsula as well as those observed in this study. In contrast, white annuli are absent or broken and indistinct ventrally with no division of black bands across the ventral surface in *H. c. calligaster* specimens from mainland Luzon (Fig. 2A). This results in the pattern of red and black bands separated by narrow or indistinct white annuli, dissimilar to the *Bracca* larvae and the Bicol Peninsula coral snake.

Other color patterns differences are also observed in *H. c. calligaster*, *H. c.* cf. *mcclungi*, and the *Bracca* sp. The lepidopteran larvae possess a greater number of black bands between red bands than either coral snake subspecies. Additionally, the red bands of the caterpillar encircle the entire body, whereas they are restricted to the ventral surface of the coral snakes. However, observed defensive movements of both snakes and caterpillars resulted in the flashing of the brightly colored red bands (Brown 2006; this study).

These observations suggest that a mismatch in color and pattern exists between the model (snake) and potential mimic (lepidopteran larvae) across their range of sympatry in the northern Philippines. While the lepidopteran larvae shares a general resemblance to both subspecies of *H. calligaster* on Luzon Island, its banding pattern is more similar to *H. c. mcclungi* than it is to *H. c. calligaster*. This may indicate that the model/mimic system evolved between a single subspecies of Philippine coral snake (*H. c. mcclungi*) and that the lepidopteran does not vary geographically in correspondence with separate subspecies of coral snake as was proposed as a possibility in Brown (2006). Despite the observed differences, the caterpillar's aposematic coloration may be similar enough to coral snakes on Luzon Island to reduce avian predation pressures. An innate prey avoidance behavior in the Bicol Peninsula may extend well past the range of close correspondence between the model and the mimic banding patterns.

Although experimental studies of coral snake mimicry have been successfully conducted (e.g., Brodie 1993; Brodie and Janzen 1995; Brodie and Moore 1995), no experimental confirmation of a model/mimic system has been made for these two species. The sympatric occurrence and striking morphological similarity between snakes and caterpillars seems to be restricted to the Bicol Peninsula of Luzon Island (Fig. 1). If the color pattern is in fact reducing avian predation on the caterpillar, it would be interesting to experimentally determine how quickly the learned avoidance behavior dissipates as geographic distance increases from regions of sympatry. Assuming the close resemblance of caterpillar to *H. c. mcclungi* is a case of mimicry, toxicity analysis should be conducted to determine whether *Bracca* sp. larvae are toxic, or if the caterpillar is a palatable mimic. It remains unknown whether a species of *Bracca* sharing similar color patterns co-occurs with the other Philippine coral snake subspecies, *H. c. gemiannulis* from Cebu, Negros, and Panay Island (Brown 2006; Leviton 1963).

Acknowledgments.—We thank the Protected Areas and Wildlife Bureau (PAWB) of the Philippine Department of Environment and Natural Resources (DENR). Field work was conducted following IACUC approval (Brown 158-01-1110). Funding was provided by a Fulbright-Hayes Fellowship and NSF DEB 0804115 to CDS and NSF EF-0334952 and DEB 0743491 to R. Brown. We are especially grateful for the assistance of J. Brown and J. Siler during our fieldwork. Critical reviews of the manuscript were provided by R. Brown and D. McLeod.

Both *Crocodylus johnstoni* (Australian Freshwater Crocodile) and *C. porosus* (Australian Saltwater or Estuarine Crocodile) occur in northern Australia. *Crocodylus porosus* is accepted as being dangerous, known to attack humans and responsible for at least 25 fatalities in Australia between 1971 and 2009 (Caldicott et al. 2005; C. Manolis, pers. comm.). *Crocodylus johnstoni*, on the other hand, is widely considered harmless to humans (e.g., Crocodile Specialist Group 2008; Webb and Manolis 2007). There are no recorded human fatalities from *C. johnstoni* (C. Manolis, pers. comm.) and locals frequently swim with this species, believing that it does not bite people (pers. obs.). Although it is acknowledged that *C. johnstoni* is capable of inflicting injury, both local people and experts are reluctant to believe they attack humans (Anonymous 2006; Caldicott et al. 2005; Crocodile Specialist Group 2008).

In September 2008, two *Crocodylus johnstoni* attacked one of the authors (KNH) in the Throssell River of the Kimberley Region of Western Australia in the presence of the second author (AS). This experience provides evidence contrary to the prevailing opinion that this species is harmless to humans. We have found additional accounts of *C. johnstoni* attacks on humans in northern Australia, but the difficulty we had in acquiring this information suggests that the widespread belief that *C. johnstoni* is harmless may in part be perpetuated by a lack of reporting, reluctance to lend credence to such accounts, and consequently a lack of media attention. These factors impede a full understanding of this species' behavior and jeopardize public safety. We discuss these issues further using our case study and compiled accounts of additional *C. johnstoni* attacks on humans in northern Australia.

Methods.—We compiled accounts of *C. johnstoni* attacks that were reported in northern Australia. Accounts were gathered between September 2008 and June 2010 from personal narratives brought to our attention, scientific literature, the internet (primarily online newspapers), and the Crocodile Attack Database (CAD) that was begun in 1971 and is maintained by Wildlife Management International in Darwin, Northern Territory of Australia (C. Manolis, pers. comm.). We included accounts where the attacking species was clearly identified as *C. johnstoni* and where there was no obvious human harassment of the animal prior to attack.

Results.—In addition to our encounter involving two *C. johnstoni*, we recorded ten other accounts of *C. johnstoni* attacks on humans in northern Australia between 1971 and 2009 (Table 1). This total is likely an underestimate given that three of the attack accounts were collected through chance personal communications (two relayed to the authors and one acquired by C. Manolis second hand [C. Manolis, pers. comm.]) and another two through personal experience, meaning that nearly half of the accounts were collected opportunistically rather than being available in the scientific literature or from news sources.

There was an average of 0.3 *C. johnstoni* attacks on humans reported annually in northern Australia between 1971 and 2009 (Table 1). The first reported attack was in 1988 and the annual number of reported attacks increased to 0.9 between 2000 and 2009. In all cases, the victims were engaged in water activities—swimming, treading water, or floating in an inner tube or on an inflatable mat—at the time of attack. Where gender of the victims was known, numbers were evenly divided between males and females. Crocodile size was estimated in five of the accounts and attacking crocodiles were reported as 1–2 m total length, with 2 m crocodiles being reported as responsible for three of those attacks. Attacks ranged from a quick bite and release to varying degrees of biting persistence until the victim escaped or resisted further bites. Most injuries were restricted to puncture wounds or cuts made directly by the teeth.

Case Study

The authors' *C. johnstoni* attacks occurred on 17 September 2008, along a remote section of the Throssell River in the Kimberley Region of Western Australia (17.43°S, 126.05°E). September is the dry season and the river was divided into a series of water holes. There was a high density of *C. johnstoni* along the river, but the water hole where the attack occurred had no visible individuals on the bank or at the surface of the water. The water hole was ca. 100 m x 20 m and contained deep, murky water. The bank was steep on both sides with boulders on one end of the river bed and a shallow bank adjoining the river bed on the other end. There was dense vegetation and a steep bank along the side of the hole where the authors entered the water.

Around noon KNH entered the water with a splash and was

FIG. 1. Hand and arm wounds from *Crocodylus johnstoni* less than an hour after attack.

followed about a minute later by AS. Moments after the second splash, KNH headed toward the bank along her previously clear path. She swam into the broadside of a crocodile. She stopped momentarily, then proceeded slightly to the left of her previous path. The crocodile circled and approached KNH from her right side, attacking at a sideways angle from the front and biting her left knee. KNH tried unsuccessfully to pull the jaws off her knee with both of her hands. KNH released the jaw to reach for an assisting hand offered by AS and the crocodile attempted a death roll. KNH successfully resisted and kept her head above water. KNH returned to the bank with the crocodile where both authors identified the species as *C. johnstoni* when the head was lifted out of the water and as being 2 m long (total length). AS gouged one of the *C. johnstoni*'s eyes until it released the knee.

Before KNH exited the water, a second crocodile bit her right arm. KNH freed herself by thrusting her arm down forcefully while twisting it to one side. This crocodile was ~1 m long and was identified as *C. johnstoni* based on shape and size of the teeth puncture wounds. Identification of the second crocodile was further supported by the abundance of this species along the river and no evidence suggesting the presence of *C. porosus*, which local people (pers. comm.) insisted do not occur in the area.

Combined injuries from the two attacks included puncture wounds on both hands and the right arm (Fig. 1), and around the left knee (Fig. 2). The left knee also sustained soft tissue damage including a small meniscus tear, sprains, and strains.

Discussion.—For many years, much attention has been focused on understanding and preventing *C. porosus* attacks on humans (e.g., Caldicott et al. 2005, Crocodile Specialist Group 2008, Gruen 2009). Little attention has been paid to the dangers of *C. johnstoni*, no doubt because of the prevailing notion that this species is harmless (e.g., Crocodile Specialist Group 2008; Webb and Manolis 2007). To the contrary, our case study, backed up by other reports we have gathered, indicates that *C. johnstoni* are capable of attack resulting in serious injury.

[1]CAD = Crocodile Attack Database.

[2]We incorporate these accounts of *C. johnstoni* attacks into our analysis because they are included in the CAD and are cited by Anonymous (2006), Caldicott et al. (2005), and Crocodile Specialist Group (2008). The original source for these accounts is Lindner (2004), but this reference does not explicitly state that attacks occurred but rather that nuisance *C. johnstoni* were removed from this site.

Available data indicate that *C. johnstoni* attacks are not as common, nor usually as severe, as *C. porosus* attacks. From 1971 to 2009 there has been an average of 0.3 reported accounts of *C. johnstoni* attacks on humans per year compared to 1.95 average accounts reported per year for *C. porosus* (C. Manolis, pers. comm.). There are no known cases of human fatality from *C. johnstoni* compared to 25 recorded cases from *C. porosus* between 1971 and 2009 (C. Manolis, pers. comm.). Nevertheless, given the apparently limited reportage, acceptance, and recording of *C. johnstoni* attack accounts, one must wonder how many other attacks have occurred and are not known. In our data set there is a suggestion of an increase in the number of *C. johnstoni* attacks on humans in the last decade. This may indicate an actual rise in the number of attacks, but may also reflect easier access to more recent attack accounts.

Our analysis of available information suggests that improved data collection and access to that data is needed if information on *C. johnstoni* attacks are to be available and useful for both understanding this species' biology and for informing public safety. The IUCN Crocodile Specialist Group's recommended repository for crocodile attack information in Australia is Wildlife Management International's Crocodile Attack Database (CAD). Given that only a third of the attacks compiled here were also in the CAD, this resource appears to be severely underutilized with respect to *C. johnstoni*. While not an unusual situation for data bases of this sort (Fergusson 2002), it remains troubling. One problem is that the data base is not easy to find. Google searches using reasonable search criteria are unable to find a match within the first ten pages of search results. In addition, there is no online data sheet for easy submission and data contained within the CAD are not readily available online.

Equally critical is the encouragement of reporting in the first place. Our experience and findings suggest that *C. johnstoni* attacks deserve more initial credibility and reportage of their details needs to be encouraged. Whether there has been an actual increase in the number of *C. johnstoni* attacks in the last decade or not, the threat of more attacks in the future is real. The numbers of people visiting remote areas continues to rise as improved technology and infrastructure make more challenging locations increasingly accessible. Since *C. johnstoni* have been observed to be less wary of humans and more prone to aggressive displays in areas where they are not regularly exposed to humans (Webb 1985), increased visitation to remote areas could increase the number of attacks. Attacks may become more frequent across this species' range regardless of remoteness as human populations rise, increasing the probability of negative encounters. Clearly outlined safety guidelines exist for *C. porosus* (e.g., Queensland Government 2008). Similar guidelines should be developed and publicized for *C. johnstoni.* However, little is definitively understood in order to undertake such a task. Improved data will be needed to assess the triggers for *C. johnstoni* attack. The only clear evaluations from the data set compiled here is that all victims were in the water at the time of attack and there is no apparent gender bias. It appears that larger *C. johnstoni* are more prone to attack and that attacks are more likely to occur in April or September, but these conclusions are not much more than indicative. Standardized data collection is necessary to limit gaps in the data set and to ensure that the data being collected are useful for understanding *C. johnstoni* attack triggers.

We emphasize the importance of documenting all *C. johnstoni* attacks in a standardized, easily accessible format. Acquiring such data will require an educational campaign to alter the perception that *C. johnstoni* are harmless, to one of recognizing their potential to attack and the need to report such incidents. Future research should pay discerning attention to the details of each recorded attack to increase our understanding of *C. johnstoni* attack triggers. This information is essential to understanding the biology of *C. johnstoni*, improving its conservation and management and, as we have shown in this paper, human safety.

Acknowledgments.—We thank Charlie Manolis for providing access to the CAD, as well as additional *C. johnstoni* information and a helpful review of our manuscript. We thank Matthew Brien and Grahame Webb for information; two victims who will remain anonymous for sharing their stories with us; and James Kushlan and two anonymous reviewers for constructive advice on the manuscript. Additionally, we thank all the people who facilitated our evacuation and a safe recovery, including Sarah Legge, Dan Swan, Richard Kingswood and other staff from the Australian Wildlife Conservancy's Mornington Wildlife Sanctuary, Mt. House Station, the Royal Flying Doctor Service, and the Derby Hospital, as well as following care and treatments from various professionals, friends and family in Miami, Florida, and other areas of the USA.

Kälin's 12-12 as an Indicator of Size in Crocodylia

ASHLEY PEARCY
Institute of Biology, Leiden University
2300RA Leiden, the Netherlands
e-mail: ashley.pearcy@gmail.com

The search for the biggest crocodile is a frequent endeavor not only for spectacle but also for the sake of science and evolutionary studies (Whitaker and Whitaker 2008). Crocodile skulls are more often than not the only preserved element of the skeleton. Since crocodile skulls grow in allometry with body size, they are frequently used as a proxy for physical size of a specimen (Greer 1974; Woodward et al. 1995). However, there is often confusion over the best location for determining size (Ross and Pearcy 2009). This article reexamines and suggests Kälin's 12-12 (Kälin 1933) as a best predictor of skull size in crocodilians and possibly an accurate and easily identifiable proxy for body size in crocodilians.

Previously, total skull length has been considered the independent variable indicating size (Radinsky 1981; Simpson et al. 1960). There has been debate on this assumption as width at the back of the jaw has also proven to vary considerably (Monteiro and Soares 1997). Most commonly used has been the ratio between the two aforementioned measurements (Busbey 1995; Verdade 2000).

These commonly used measurements, however, are often susceptible to notable variation within the ontogenetic process and change outside of this process. For example, hatchling skull shape, specifically in the rostrum, is different from that of the adult of the same species (Dodson 1975; Hall and Portier 1994; Verdade 2000). Outside of the ontogenetic process more problems tend to occur. Depending on physical environmental conditions and stress factors, skull shape as described by total length and total width can vary dramatically, as commonly seen in captive populations (Hutton 1987). Growth can be extremely variable within species (Hall and Portier 1994; Hutton 1987). This variability can be especially noted when comparing healthy vs. unhealthy and captive vs. wild specimens (Black and Loveridge 1975; Coulson et al. 1973; Joanen and McNease 1974; Whitaker and Whitaker 1977). While traditional measurements of total length and total width can be informative of how large an individual is, the disparity between size of individuals, caused by ontogenetic factors, and average size of the species can reduce application among comparative morphometric studies.

Based on a large dataset, I identify the most applicable and least variable indicator of skull size within and across species. Furthermore, I discuss this measurement as an applicable indicator of body size based on the criteria derived from a number of sources (Hall and Portier 1994; McIntosh 1955; Pierce et al. 2008; Verdade 2000): 1) low variability within species; 2) correlation with body size; 3) functional importance; and 4) repeatability.

Methods

Measurements were made from the jaw line at the center of the post-orbital bar across the head to the opposite jaw line at the same point (Fig. 1c,d; Kälin 12-12). On skin-covered specimens this area is identified as the space between the earflap and the back of the eye. The distance from midline at this width (Fig. 1g) to the tip of the snout (Fig. 1a) is Kälin's 12-3.

Only one traditional width measurement, cranial width (CW), was examined. That is the width of the jaw at Kälin 1 (1933) as defined by the widest point on the quadrojugal bone (Fig. 1:e,f). Total length of skull (TSL) is from the back of the cranial ridge (Fig. 1b) along the midline to the tip of the snout (Kälin's 6-3) (Fig. 1a). All measurements were taken in centimeters.

Data were collected from museum specimens (N = 152) of all 23 species of extant crocodilians. From these specimens, the four aforementioned measurements were taken. Juveniles and noticeably deformed specimens were not used if possible. A separate data set was used, where whole specimens, not only skulls, were examined for comparison of measurements to the total body. These measurements of total body length (TBL) and snout-vent length (SVL) were collected on 21 wild *Osteolaemus tetraspis* by a crocodile expedition throughout central Africa (Zoer 2010). A rope was used to take the measurement on the crocodile and then measured along a tape measure. TBL was taken on the dorsal surface, while SVL was measured along the ventral surface.

By using Pearson correlation analyses the Kälin 12 measurements were compared to traditional measurements using SPSS 16.0. One-way ANOVA's were run to test for the difference between ratios. Standard deviations and t-tests (Dinov 2005) were then calculated within each measurement type for each species in Microsoft Excel 2008. A principal components analysis was used to better define the difference between the Kälin 12 ratio and the

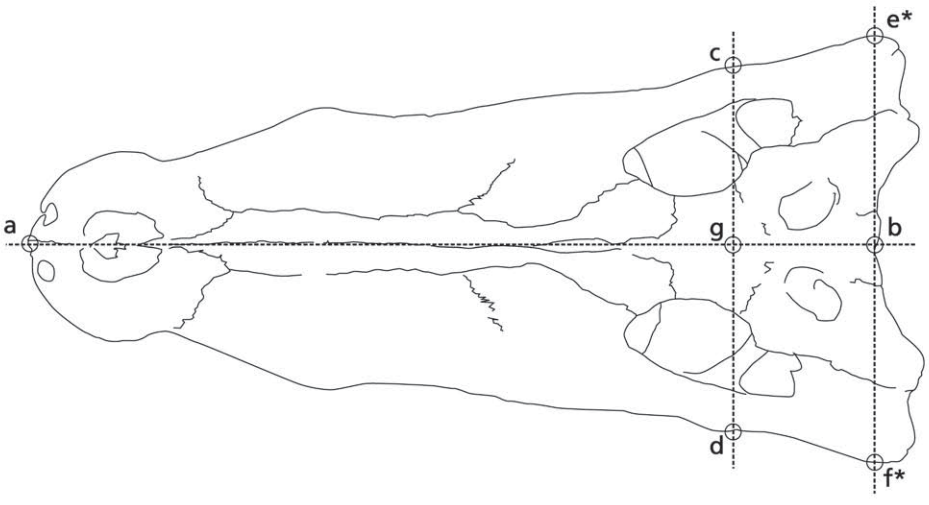

Fig. 1. Measurements taken from crocodilian skulls; a–b: total skull length, c–d: Kälin 12-12, e–f: total width of skull, a–g: Kälin 12-3. Asterisks mark traditional measurement.

traditional ratio as they relate to species differentiation.

Results

Correlation analyses of total length (TSL) and total width (CW), and TSL and Kälin 12-12 for all species show positive correlations between the Kälin 12 measurement ratio (R = 0.875) and the traditional measurement ratio (R = 0.908). The ratio of CW to TSL did not differ significantly from the ratio of Kälin 12-12 to Kälin 12-3 (ANOVA: F = 0.54, df = 1, p = 0.46).

Standard deviations for each measurement within each species (Table 1) were lower for Kälin 12 measurements than for traditional measurements. Kälin12-12 was significantly less than CW ($t = -5.1$, $df = 20$, $p < 0.001$) and Kälin 12-3 was significantly less than TSL ($t = -4.320$, $df = 20$, $p < 0.001$).

A principal components analysis of the Kälin 12 ratio and the traditional ratio found that 97.34% of the variation was accounted for in principal component 1. Case loadings show that PC1 was driven by the Kälin 12 ratio (0.82) rather than the traditional ratio (0.58) to separate by species.

Data from 21 *Osteolaemus tetraspis* revealed the standard deviation of the ratio of Kälin 12-12 to total body length (0.175) was lower than the standard deviation of the ratio of CW to body length (0.192). Within the same dataset, the standard deviation of width at Kälin 12 to snout-to-vent length (SVL) to (0.0138) was lower than that of cranial width to SVL (0.282). A correlation analysis showed slightly higher correlation between SVL and Kälin 12-12 (R = 0.977) than between SVL and CW (R = 0.958).

Discussion

The Kälin 12-12 and 12-3 measurements are a better indicator of skull size than cranial width and total skull length measurements. Through the PCA, the Kälin 12 measurement ratio is noted as a stronger driving force than the traditional ratio for species division. Four criteria were used to further investigate the usability of the Kälin 12 measurements as a measurement of skull and body size, finding it to be of value over the other measurements.

Low variability.—The best size measurement is the least variable one (McIntosh 1955). The Kälin 12-12 measurements had a lower standard deviation within species than did the measurements of total width and total length. The lower deviations within species support the hypothesis that the Kälin 12-12 and Kälin 12-3 measurements are less susceptible to growth outside of the ontogenetic process and exhibit less variation than other methods.

Kälin 12-12 also occurs in an area, near the orbits, of reduced allometric growth coefficient (Verdade 2000; Wu et al. 2006), which means that the growth rate of this area is reduced compared to snout length and width at the back of the jaw, which accounts for the lower deviation. The reduced growth of this portion of the

Table 1. Sample size, size range, and standard deviations within measurements by species.

			Standard deviations			
Species	N	Range CW (cm)	Kälin 12-12	CW	Kälin 12-3	TSL
Alligator mississippiensis	13	16.10–30.28	3.67	5.04	6.48	7.31

skull at later stages of crocodile development is visible through a study of *Crocodylus novaeguineae* (Hall and Portier 1994). These studies do not specify the exact position of Kälin 12-12, thus inferences are made from the orbital width and postorbital cranial ridge width to snout-vent length. One study on *C. niloticus* used a measurement from the point anterior to the orbits to the tip of the snout, finding that it grows isometrically relative to head width (Hutton 1987). This is the closest measurement comparable to Kälin 12-3. As the area around the orbits is less prone to growth extremes, it represents a more accurate figure for skeletal size. This can be especially important in captive populations where growth responds to temperature, population density, and food (Blake and Loveridge 1975; Coulson et al. 1973; Joanen and McNease 1974; Whitaker and Whitaker 1977), thereby creating a comparable database. For skin-covered specimens, the location of Kälin 12-12 is also an area of reduced soft tissue, which could prevent discrepancies in measurements based on the thickness of soft tissue.

Correlation with body size.—When compared to body length and snout-vent length, Kälin 12-12 has a lower standard deviation than CW. This shows that Kälin 12-12 is a viable measurement of size even for total body length in *O. tetraspis*. As *O. tetraspis* is the smallest crocodile, the lower standard deviation of Kälin 12-12 may be due in part to the crocodile's small size. However, the previous analysis shows the same positivity for Kälin 12 in skull size for all species. The direct proportions between the skull and body of crocodilians (Chentanez et al. 1983; Hutton 1987; Verdade 2000) supports the conclusion that Kälin 12-12 is a viable measurement relatable to total body size in species other than *O. tetraspis.*

There is a high level of integration of the differing parts of the skull meaning change in one part will result in the restructuring of the entire skull (Monteiro et al. 1997). We would, therefore, expect a similarity between the Kälin 12 measurements and CW and TSL and their respective ratios, as they are related measurements of length and width, which is a verifiable proportion within crocodilians (Chentanez et al. 1983; Hall and Portier 1994).

Functional importance.—Although functional importance is not always a necessity for determining a measurement point, it can be beneficial for application to ecology and functional morphology. The area of the skull surrounding the orbits has a reduced susceptibility to growth caused by environmental factors and it is a physically strong point on the skull. In battle, crocodilians have been known to bash heads (Webb and Manolis 1989) with the point of contact often near Kälin 12. In spite of the dangers to either side of the focal point such battles rarely seem to cause damage. Due to the closing of the secondary palate, the crocodilian rostrum is much stronger near the orbits. According to Busbey (1995) this leads to less tension from torsional loads associated with feeding behaviors.

Repeatability.—The post-orbital bar offers an area easily identifiable on skulls. On skin-covered specimens there is a minimum margin of error as the distance between the earflap and the eye is small. Although the widest part of the skull seems easier to identify than Kälin 12, in many skulls from collections, the bone is chipped or broken at the widest part. The widest part of the skull can also be open to interpretation ranging from anywhere between the back of the quadrojugal bone to the widest part of the quadrojugal.

Conclusion

Based on the aforementioned criteria, the Kälin 12 measurements prove to be slightly better than the traditional width measurement at the widest part of the skull for determining size of both skull and body. It offers an easily identifiable area which is less susceptible to growth due to environmental factors and the low amount of soft tissue in this area also reduces the bias already found in skin-covered vs. clean specimens. Kälin 12 measurements may also be better measurements within captive populations, where malnourishment and stressful conditions can lead to abnormal growth. Kälin 12-12 is also of physiological importance being one of the stronger areas of the crocodilian skull. The use of Kälin 12 could benefit comparative anatomical, evolutionary, and ecological studies of crocodilians by presenting a measurement meeting proven criteria for usability.

Acknowledgments.—I thank Franklin D. Ross for the measurement and the challenge to test a hypothesis, Zeno Wijtten for assistance in data collection and manuscript revisions, and Roland Zoer, Rogier de Bouer, and Jeroen Koorevaar for sharing data from their Africa expedition. Frans Witte and Nicole Ortega provided comments on the manuscript. I acknowledge personnel associated with Royal Belgian Institute of Natural Sciences, Forschungsinstitut und Naturmuseum Senckenberg, Naturalis, Zoological Museum Amsterdam, and Paris MNHN for access to their crocodilian skull collections.

The Eastern Indigo Snake (*Drymarchon couperi*), a large (adults from 1.5–2.6 m total length [Stevenson et al. 2009]) diurnal species, is imperiled and federally listed as "Threatened" due to population declines attributable to habitat loss/fragmentation and declining Gopher Tortoise (*Gopherus polyphemus*) populations (United State Fish and Wildlife Service [USFWS] 2008). In southern Georgia and portions of its Florida range, *D. couperi* is closely associated with xeric sandhill habitats and Gopher Tortoise burrows, and adults often use tortoise burrows for overwintering sites (Diemer and Speake 1983; Hyslop et al. 2009a; Stevenson et al. 2003). The burrows of adult tortoises average 4.5 m long and 2 m deep (Diemer 1992), but in aeolian sand ridge habitats (see Ivester and Leigh 2003) adjacent to blackwater streams in southeastern Georgia, burrows are commonly 6.1–9.1 m in length (D. Stevenson, unpubl. data). Adult *D. couperi* are frequently surface-active during the winter and may bask or shed their skins near burrows, or move between burrows, during periods of mild (10.0–16.7°C) temperatures (Speake et al. 1978; Stevenson et al. 2009). Although habitat use is varied and less associated with sandy habitats in peninsular Florida, *D. couperi* occur in xeric uplands and regularly use tortoise burrows as far south as south central Florida (Layne and Steiner 1996). Because of the extensive time they spend in tortoise burrows and other below-ground refugia, adult *D. couperi* are difficult to locate during field surveys. Developing reliable survey methods for this species is an important priority for *D. couperi* research and monitoring efforts (USFWS 2008).

Recent studies demonstrate that detector dogs have potential

as a non-invasive method for locating target wildlife species in their natural habitats (Nussear et al. 2008; Reindl-Thompson et al. 2006; Smith et al. 2003). However, few studies have used detector dogs to survey for snakes. Klauber (1956) mentions a "hound" from Florida that was trained to trail rattlesnakes (*Crotalus adamanteus*) and "bay" them when found; this dog located ca. 500 rattlesnakes in two years. Detector dogs located Brown Tree Snakes (*Boiga irregularis*) in cargo (Engemann et al. 1998, 2002), and, recently, the New Jersey Division of Fish and Game, Endangered Species Program used a trained dog to locate Northern Pine Snakes (*Pituophis m. melanoleucus*) adults and eggs (Dave Golden, pers. comm., 2007).

In an effort to develop an efficient and accurate survey method for locating *D. couperi* in the wild, we conducted a pilot study to test the effectiveness of a trained detector dog at locating Eastern Indigo Snakes. We conducted: 1) experimental field trials to evaluate a trained detector dog's ability to find live *D. couperi* and shed skins of *D. couperi* in the species' natural habitat; 2) actual field surveys, using a trained dog, to survey sites known to support *D. couperi*.

Methods

Dog Selection and Training.—We trained a dog (male, Labrador-mix, 5 years old, 30 kg) on loan from PackLeader Conservation Detector Dogs, Gig Harbor, Washington, USA 98329 to locate *D. couperi* using a combination of detection training techniques. We first introduced the dog to the odor of *D. couperi* at PackLeader in Washington State in October 2008. We randomly placed sections of shed skins (from multiple *D. couperi* collected from the wild in southern Georgia and central Florida) in a large field and allowed them to sit for up to 0.5 h. We then allowed the dog to roam the field, and when the dog showed interest in a shed skin the dog was commanded to sit and was rewarded with its play object (tennis ball). We continued similar shed-skin exercises with the dog over the next two weeks until the dog reliably located the samples.

Next, we trained a handler on the fundamentals of working the dog in the natural habitat of *D. couperi*. We conducted this training at the Orianne Indigo Snake Preserve, Telfair County, Georgia on 17 dates in November, 2008. Well-drained xeric sandhills on-site support resident populations of Gopher Tortoises and *D. couperi*. During this phase of training, we continued field exercises with shed skins and also introduced the dog to the scent of live *D. couperi*.

To train the handler, we set up area-search exercises wherein we hid varying numbers (7–14) of *D. couperi* shed skin sections. The trainer accompanied the handler to point out the dog's working style and to explain the effects of environmental factors on scent. In the first series of exercises, the handler and observer knew the location of the hidden shed skins. Gradually, sheds at undisclosed locations were added to the search area, and the size of the search area was increased (to add time and distance to the search).

When the handler had learned the various changes of behavior exhibited by the dog and could accurately determine when the dog was appropriately "indicating" the location of shed skin from a *D. couperi*, shed skins from several other snake species that are sympatric with *D. couperi* (Eastern Coachwhip [*Coluber f. flagellum*], Florida Pine Snake [*Pituophis melanoleucus mugitus*], and Eastern Diamondback Rattlesnake [*C. adamanteus*]) were added to the exercises. When the dog showed interest in the non-target odors (other than rattlesnake), the handler verbally corrected him off the non-target odor and reinforced on the target odor. When the dog showed interest in rattlesnake odor, the handler administered a physical correction and reinforced on the target odor. The dog quickly learned to avoid rattlesnake odor and to ignore non-target species odors. The dog's avoidance behavior (a "sideways look" at the rattlesnake [or rattlesnake shed] followed by a movement away from the area prior to returning to search mode) was clearly distinctive from the change of behavior it exhibited when expecting a reward for finding the target species. Upon locating the target (i.e., *D. couperi* shed skin), the dog "indicated" by expressing a suite of behaviors including sitting and/or remaining stationary, vigorous tail-wagging, and crouching. We continued training in this fashion until the handler was capable of working exercises independently. The handler and dog found more than 90% of the hidden shed skins during these training exercises.

We conducted several exercises near the end of the training period to introduce the dog to the odor of live *D. couperi* and to the holding cages that we used in the Phase 1 field trials (*see below*). As part of this training, we used both empty cages that never held snakes and occupied cages which held live *D. couperi*. We conducted this training so that the handler would have confidence in the dog's ability to separate these odors. In successful exercises, the dog positively "indicated" on the live *D. couperi* as he did above for shed skins of the species.

Phase 1 Trials.—To assess the dog's ability to recognize *D. couperi* scent, we conducted controlled field tests at one site each in Georgia (Joseph W. Jones Ecological Research Center [JERC], Baker Co., Georgia, USA) and in Florida (Apalachicola Bluffs and Ravines Preserve [ABR], Liberty Co., Florida, USA). To control for the possible effects of wild *D. couperi* present on-site, we selected sites not inhabited by *D. couperi* (Gunzberger and Aresco 2007; Smith et al. 2006; D. Printiss, pers. comm., 2008).

We conducted a total of 108 Phase 1 trials (52 at JERC on 23–25 November 2008; 56 at ABR on 3–5 December 2008). At each site, we evenly distributed trials among a total of four treatments for live *D. couperi* and *D. couperi* shed skins, as follows: 1) Above-ground: A live caged snake was placed on the ground surface within 10 meters of a tortoise burrow; 2) Above-ground: A shed skin (free, not caged) was placed on the ground surface within 10 meters of a tortoise burrow; 3) Below-ground: A live caged snake was placed flush with the entrance of a tortoise burrow, or situated a short distance (≤ 0.5 m or less) inside the burrow tunnel; 4) Below-ground: A shed skin (free, not caged) was placed flush with the entrance of a tortoise burrow, or a situated a short distance (≤ 0.5 m or less) inside the burrow tunnel.

For live snake trials, we used adult *D. couperi* (Total length: 140–200 cm) that we captured by hand from sites in Georgia (N = 3 ♂, 1 ♀) or in Florida (N = 2 ♂, 1 ♀). At our Georgia study site (JERC), we used snakes found in Georgia; similarly, we conducted trials at our Florida study site (ABR) using snakes found in Florida. For shed skin trials, we used recent (< 3 months old) shed skins from adult *D. couperi* found in the wild.

When conducting live-snake trials, we placed one *D. couperi* in a specially-designed, escape-proof holding cage (Herpetological Associates, Inc., Dunnellon, Florida, USA). We constructed two different sizes of holding cages so they would fit into tortoise burrows of varying widths. The smaller cages we made measured 18.3 cm wide, 11.2 cm high, by 61.5 cm in length, whereas the larger cage measured 21.0 cm, 13.0 cm, by 101.5 cm in length. We built holding cages with 15 cm plywood ends, and on one end of the cage we installed a small locking door. We made the walls of the cage of rubber-coated hardware cloth with 1.8 cm square openings. So they would fit into tortoise burrows, we constructed the cages so that the top was arched and the bottom was flat, thus approximating the shape of a tortoise burrow in cross-section.

We placed the cage holding the live snake (or the *D. couperi* shed skin) in the selected test location (i.e., on the ground within 10 m of a tortoise burrow, or just inside the entrance of a tortoise burrow). On field trial dates, we dedicated one individual of our study team to the handling and placement of cages holding live snakes and shed skins to minimize transfer of scent odors; forceps were used to position and retrieve shed skins between trials. We concealed our live-snake-in-cage sets by wrapping camouflage netting around the exposed portions of the cage. On above-ground trials, we positioned cages holding live snakes and shed skins so that they were partially or mostly concealed by ground cover vegetation and not readily visible to the dog survey team/handler.

On each individual trial, we had the dog handler, the handler's field assistant, and the dog visit three tortoise burrows: 1) one burrow with a hidden target (i.e., either a live snake above-ground, a live snake below-ground, a shed skin above-ground, or a shed skin below-ground); 2) one burrow that was empty (i.e., no hidden targets), and; 3) one burrow that was either empty (all shed skin trials) or, for all live snake trials, one burrow with a control (i.e., an empty cage hidden above or below-ground—to verify that the dog was not indicating on the cages). We conducted trials in sets of four, in varying order: snake above-ground; snake below-ground; shed skin above-ground; shed skin below-ground. To ensure that the dog was not following human scent or keying on flags, we marked all tortoise burrows used in these field trials with similar-colored flagging tape tied to nearby vegetation, and we had a supporting biologist introduce human scent at all burrows (by rubbing his hand over the sand inside the burrow and on the apron) while setting up trials. We removed the dog and handler from the immediate area (i.e., minimum 100 m distant) when preparing trial sets. We allowed our live snake and shed skin sets to sit for ca. 10–20 minutes to allow some airborne scent dispersal before bringing the dog and handler to the area.

Next, we had the handler lead the dog to each of the three burrows that constituted an individual trial. We classified a particular trial as successful if the dog correctly indicated the presence of an indigo snake or shed; those trials where the dog did not indicate at/near burrows where we had hidden a snake or shed skin we classified as errors of omission; trials where the dog indicated at/near burrows where we had not hidden a snake or shed skin we classified as commission errors. On all Phase 1 trials, the dog handler was accompanied by a field assistant who helped orient her and lead the dog to trial burrow locations.

We used data from these trials to calculate the proportion of trials where the dog successfully signaled on live *D. couperi* or shed skins. We used a Chi-square goodness of fit test to compare dog success among the four treatments (Above Ground-Live Snake, Above Ground-Shed Skin, Below Ground-Live Snake, Below Ground-Shed Skin). We further classified unsuccessful trials by calculating the proportions that were omission versus commission errors.

Phase 2 Trials.—For the second part of our study, the dog and handler conducted 1-h long field surveys for *D. couperi*. We surveyed non-overlapping xeric sandhill sites that supported numerous active/inactive tortoise burrows and resident, overwintering *D. couperi*. We conducted a total of 26 1–h long trials (2–4 trials per survey date) on nine dates from 8–23 January 2009 at a total of seven sites: Fort Stewart Military Installation (FSMI), Bryan Co., Georgia (N = 3); FSMI, Evans Co., Georgia (N = 3); Broxton Rocks Preserve, Coffee Co., Georgia (N = 5); General Coffee State Park, Coffee Co., Georgia (N = 3); Orianne Indigo Snake Preserve, Telfair Co., Georgia (N = 3); Withlacoochee State Forest, Citrus/Hernando counties, Florida (N = 7); Chassahowitzka Wildlife Management Area, Hernando Co., Florida (N = 2).

Prior to beginning the surveys, we presented the dog survey team (comprised of the dog, the dog handler and her field assistant) with an aerial photograph of the survey site, oriented them with respect to nearby primitive roads, wetlands, and other landmarks, and defined the area of potential habitat to be surveyed. We did not flag tortoise burrows. We then directed the dog survey team to search for one full hour; the dog team made a single pass through each survey area, attempting to visit and search all tortoise burrows they could locate. The field assistant used a compass and aerial photo to orient the dog and the dog handler and keep them on a steady compass bearing. The dog team began the survey at the downwind end of the survey area and progressed upwind, maximizing the dog's exposure to possible *D. couperi* scent. We conducted these surveys from mid-morning through mid-late afternoon on clear or rain-free days (i.e., weather conditions that would prove suitable for *D. couperi* surface activity).

If the dog indicated at the entrance of an individual tortoise burrow (suggesting the presence of a live *D. couperi* or recent shed skin within the burrow), we immediately scoped the burrow with a remote video camera attached to a 9 m section of tubing (Gopher Tortoise Burrow Camera, Southern Ecosystems Research, Auburn, Alabama, USA) in an effort to determine the presence of a live *D. couperi* or shed skin. If *D. couperi* were not documented, we placed a large single-opening funnel trap at the mouth of the burrow in an effort to capture any resident *D. couperi* as they exited the burrow. We shaded funnel traps and checked them 2–3 times per day during daylight hours.

Results

Phase 1 Trials.—The detector dog was correct on 91% (98 of 108) of the Phase 1 trials. Overall, the dog was more successful during shed skin trials than during live snake below-ground trials ($\chi^2 = 13.928$, Df = 3, P = 0.003). The dog was correct in all (100%) of 54 shed skin trials—both above-ground and below-ground. Of the live snake trials, the dog was correct 81% of the time (44 of 54 trials), with 88% success (23 of 26 trials) on above-ground trials,

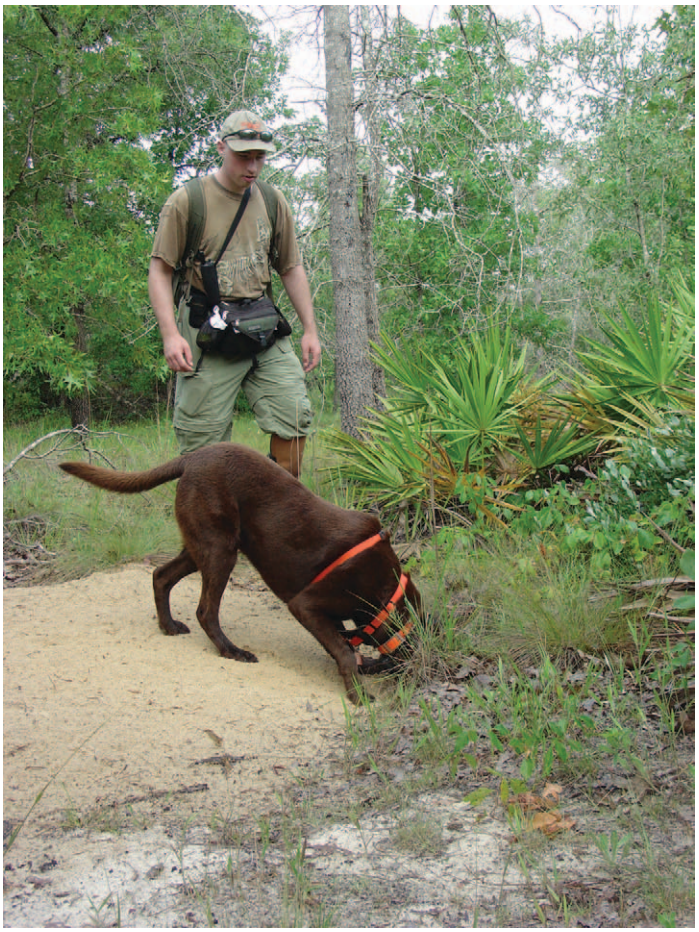

FIG. 1. A specially trained wildlife detector dog ("C.J.") surveys a Gopher Tortoise (*Gopherus polyphemus*) burrow for Eastern Indigo Snakes (*Drymarchon couperi*), Wheeler County, Georgia, USA. Photo by Dirk J. Stevenson.

and 75% success (21 of 28 trials) on below-ground trials. Thirty percent (3 of 10) of the unsuccessful trials were commission errors, all of which occurred on below-ground trials, while 70% (7 of 10) of the unsuccessful trials were omission errors, four of these were below-ground trials.

Phase 2 Trials.—On 26 1-h long Phase 2 trials, the dog team surveyed a total of 496 active/inactive Gopher Tortoise burrows at seven sites. During these surveys, the dog located 11 individual *D. couperi* shed skins and indicated at another 18 tortoise burrows. Seventeen of these 18 burrows were examined with the tortoise burrow camera; *D. couperi* were observed in three separate burrows at distances of 3.7, 6.7, and 7.0 m. All of the remaining burrows were trapped from 2–10 days; no *D. couperi*, or any other snakes, were captured by these efforts.

DISCUSSION

Our study suggests that wildlife detector dogs have value as a field survey method for the Eastern Indigo Snake (*D. couperi*). During controlled field tests (Phase 1 Trials), the detector dog used in this study successful located 81% of live *D. couperi* and 100% of *D. couperi* shed skins.

The dog had very little field training with live *D. couperi* prior to Phase 1 trials, and we strongly suspect that the dog would have performed better with additional training with live snakes prior to these trials. During informal training exercises and field surveys conducted 10 December 2008–27 January 2009 at the Orianne Indigo Snake Preserve (Georgia), the dog found seven individual *D. couperi* (a total of 11 times) on the surface near tortoise burrows, and four *D. couperi* below-ground in tortoise burrows. Additionally, the dog indicated at the entrances of 12 tortoise burrows, four of which were confirmed (by scoping with the tortoise burrow camera) to contain *D. couperi*.

On Phase 2 Trials, the dog confirmed the presence of *D. couperi* at 6/7 sites surveyed, finding three *D. couperi* below-ground inside tortoise burrows and 11 *D. couperi* shed skins above-ground. However, the dog may have falsely indicated snake presence at some of those Phase 2 tortoise burrows where he signaled the presence of a snake below-ground inside the burrow (N = 15). Despite our lack of success in documenting *D. couperi* via burrow camera and trapping surveys, we cannot say conclusively that *D. couperi* were not present in these burrows. Although *D. couperi* are occasionally observed by tortoise burrow camera surveys, scoping burrows is unreliable at detecting the presence of *D. couperi* because the terminus of many burrows cannot be reached with a burrow camera due to burrow length, burrow curvature, inanimate obstacles (e.g., plugs of pine straw, tree roots), or the presence of the resident tortoise partway down the tunnel shaft blocking progress of the camera (Smith and Dyer 2003; Stevenson et al. 2003).

Eastern Indigo Snakes have been documented by the following field methods: 1) visual encounter surveys at or near tortoise burrows in sandhill habitats (Diemer and Speake 1983; Stevenson et al. 2009); 2) single-opening funnel traps placed at the entrances to tortoise burrows (Lips 1991); 3) motion-activated cameras placed at tortoise burrows (Alexy et al. 2003); 4) remote video cameras ("tortoise burrow cameras") to examine the interiors of tortoise burrows (Hipes and Jackson 1996; Stevenson et al. 2003); and 5) drift fence arrays using large "box" traps (Hyslop et al. 2009b). Except for visual encounter surveys, most of the survey methods listed above are either not particularly effective and/or are extremely labor-and-time-intensive (Hyslop et al. 2009b; Smith and Dyer 2003). In southern Georgia, visual encounter surveys at tortoise burrows conducted by experienced herpetologists are often effective in locating *D. couperi* (and *D. couperi* sheds) during the cooler seasons (Hyslop et al. 2009b; Stevenson et al. 2003, 2009). However, human searchers vary in the speed at which they visit burrows, their ability to accurately discern snake tracks, and their ability to spot snakes on the surface (Hyslop et al. 2009b).

Both canine surveys and visual encounter surveys may locate live *D. couperi* or shed skins on the ground near tortoise burrows. During field training, the dog found several live *D. couperi* under natural conditions on the surface that were basking cryptically (e.g., under branches or vegetation) near tortoise burrows. And, in both training and during trials the dog often located small fragments of old *D. couperi* shed skins (hidden under debris or vegetation) that went unnoticed by human surveyors. Our study also indicates that a trained detector dog may locate *D. couperi* deep inside tortoise burrows via olfaction. Our dog was able to survey for snakes ca. 4 hours/day; frequent hydration and rest breaks were needed, and the dog did not perform well in hot

weather (i.e., > 23°C). Excessive panting during hot weather affects olfactory abilities and may lower detection rates (Smith et al. 2003). In some disturbed sandhill landscapes where native prickly pear cactus (*Opuntia* sp.) and blackberries (*Rubus* sp.) were especially abundant, the dog experienced difficulties due to abrasions to his paws from thorns. Experienced human searchers (i.e., visual encounter surveyors) often discern indigo snake tracks in the sand of tortoise burrow aprons (Stevenson et al. 2009), and visit and survey tortoise burrows at ca. twice the rate of a dog escorted by its handler and one field assistant (this study).

Possible explanations for dog errors in the field include insufficient training, mistakes due to handler errors (e.g., inadequate search), fatigue, and distractions due to encountering novel scents or wildlife species. Inappropriate weather (e.g., windless days and days following heavy rains) may also have influenced the dog's success.

Detector dog surveys were 61% and 64% successful in detecting the presence of Brown Tree Snakes planted in outbound cargo during 1998 and 1999, respectively (Engemann et al. 2002). In cases where the snakes were not located by dogs, twice as many were missed because the dog did not change its behavior in response to the snake rather than because the handler did not conduct an adequate search pattern (Engemann et al. 2002).

This study, a pilot effort, suggests that specially trained wildlife detector dogs are sometimes able to locate *D. couperi* in the wild, and the effectiveness of these "canine surveys" may be enhanced if conducted in concert with other techniques (e.g., visual encounter surveys of Gopher Tortoise burrows). Additional study will reveal whether canine surveys have value at sites where *D. couperi* is present in very low numbers, during periods when the species is not surface-active, or in habitats lacking Gopher Tortoise burrows. The detector dog used in this study located (under natural conditions) live *D. couperi* on the surface and below ground in Gopher Tortoise burrows, and frequently found shed skins that were overlooked by human searchers. Improved survey methods will enable researchers to better determine the distribution of this imperiled species, especially in regions where the species is now seemingly extremely rare or locally distributed (Florida panhandle [Gunzberger and Aresco 2007]), and may assist in developing a defensible presence/absence survey method for development projects.

Acknowledgments.—We are grateful to the following for their assistance with this project: J. Bauder, B. Callaghan, L. Carlile, T. Crites, B. Davenport, M. Elliott, K.Enge, H. Hall, J. Jensen, J. Macey, P. Moler, V. Morris, S. Osborn, D. Printiss, A. Safer, L. Smith, F. Snow, N. Spencer, and B. Willis-Stevenson. Procedures used in this study followed SSAR "Guidelines for Use of Live Amphibians and Reptiles in Field and Laboratory Research." This study was conducted under scientific collection permits issued to Christopher L. Jenkins from the Georgia Department of Natural Resources (Permit No. 21920) and the Florida Fish and Wildlife Conservation Commission (Permit No. WX08638).

Effectively marking hatchling freshwater turtles is challenging because hatchling turtles are typically small, but increase significantly in size by maturity (Plummer 1979). Ideal marks are minimally invasive, with zero or low impact on survival, are correctly identifiable upon recapture, do not affect recapture probability, remain recognizable for the length of the proposed study, and are reasonably affordable (Gibbons 1968; Plummer 1979). Marks must also remain detectable through significant growth, given turtles' dramatic increase in size between hatching and maturity. In reality, very few marking methods meet all of these criteria. Here, we discuss the merits and pitfalls of various marking methods for use in hatchling turtles. Also, we describe the use of visible implant elastomer (VIE) to mark hatchling turtles and summarize potential areas of concern regarding the use of VIE for hatchling turtles.

Why mark hatchling turtles?—Marking is useful for studying population dynamics and ecology of hatchling turtles. It is essential for monitoring "head-start" programs and related conservation endeavors. Turtle head-starting programs include *ex situ* incubation of eggs and may also involve maintenance of hatchlings in captivity until they reach a pre-determined size or age. Well-planned and carefully managed head-start programs mitigate nest predation and are potentially powerful tools for turtle conservation in populations threatened by limited recruitment (e.g., Moll and Moll 2000). Nonetheless, *ex situ* incubation and head-starting programs do not always include a post-release evaluation of their efficacy (Seigel and Dodd 2000). In the absence of post-release monitoring it is difficult or impossible to determine the effect of the program on the population(s) in question. Evaluating the success (or shortcomings) of such programs requires marking turtles to compare survivorship between nests incubated *in situ* and *ex situ.*

Consistent evaluation of the success of head-starting and other applied conservation programs (e.g., translocations, predation mitigation, and habitat restoration) allows researchers to adjust their methods to maximize success and address shortcomings as they are identified. In cases where a project is not having the desired effect, ongoing evaluation allows researchers to identify factors which merit further investigation. If a program is truly ineffective (for example, due to high mortality of released animals, or failure of head-started animals to function successfully in the wild), cancelling the program in a timely fashion minimizes the waste of precious resources. Program evaluation requires marking head-started hatchlings for post-release monitoring.

How should hatchling turtles be marked?—Several marking methods are used for adult turtles, including branding (Woodbury and Hardy 1948), paint-marking (Tinkle 1958), shell-notching (Cagle 1939), wiring metal identification plates through holes drilled in the marginal scutes (Carr 1967), tattooing (Breckenridge 1955; Woodbury 1948), flipper-tagging with plastic or metal livestock tags (e.g., Carr 1967), or passive integrated transponder (PIT) tags (e.g., Camper and Dixon 1988; McDonald and Dutton 1996). None of these methods are ideal for use with hatchling turtles.

Branding is not a reliable method, because if the brand penetrates the dermal layer, the shell may regenerate so efficiently that the brand is no longer clearly visible (Clark 1971; Woodbury and Hardy 1948). The rapid growth of hatchlings might enable them to heal over branding scars more quickly than adult individuals, further obscuring marks. Paint-marking is a useful short-term method, but the marks typically do not last longer than a few months and thus are not useful for long-term monitoring programs (Plummer 1979). Shell notching can be used on hatchlings, but their rapid growth may obscure the notch before they are re-encountered, and shell injuries sustained during growth may mimic a grown-out notch, thereby confounding individual identification (Plummer 1979). Hatchlings are too small to wire metal plates to the carapace. Thin wire tags with beads which were threaded through the marginal scutes of hatchling *Chelydra serpentina* were lost at a rate of 2.5% per week in the laboratory (Galbraith and Brooks 1984). Tattooing is useful with some adult turtles, but in hatchlings, the dye granules may spread as they grow, rendering the tattoo illegible (Plummer 1979). Flipper tags are widely used in adult marine turtles (e.g. Carr 1967), but they are of no use in species which do not have flippers, and they are too large and heavy for hatchling turtles. Finally, PIT tags have great potential for juvenile and adult turtles. However, it is debatable whether PIT tags are small enough to use safely in hatchlings of most species (Buhlmann and Tuberville 1998; Gibbons and Andrews 2004). Some studies have successfully applied PIT tags to small turtle hatchlings (e.g., Rowe and Kelly 2005), but regardless of researchers' opinion regarding their size, PIT tags are expensive. The very real possibility of low recapture rates make the financial investment required to obtain PIT tagging

equipment difficult to justify when large numbers of hatchlings must be marked for release into the wild. Thus, the methods listed here have major drawbacks when used to mark hatchlings and as a result it can be difficult to accurately determine survivorship and recapture rates for hatchling and juvenile turtles.

We tested marking hatchling turtles using VIE (Northwest Marine Technology Inc., Shaw Is., Washington, USA), a biocompatible, flexible plastic originally developed for use in the fisheries industry. Marks made with VIE have been successfully used to study frogs, salamanders, snakes, and lizards (e.g., Bailey 2004; Daniel et al. 2006; Davis and Ovaska 2001; Hutchens et al. 2008; Moosman and Moosman 2006; Regester and Woosley 2005). No adverse effects have been recorded on these species and tag loss was generally low (Ferner 2007). Park et al. (2007) evaluated the use of VIE for marking adult Chinese Softshell Turtles (*Pelodiscus sinensis*) on a turtle farm in Korea. Marks placed in the webbing between the digits of adult *P. sinensis* were retained well and were clearly visible several months after application, although marks placed in the adipose tissue of the eyelid were either lost or obscured at a high rate. They observed no adverse effects from the marks.

The elastomer is prepared by mixing a curing agent with a brightly colored liquid polymer directly before application. A small amount of the mixture is injected under the skin, leaving a visible colored dot or short line. While visibility to the naked eye is highly dependent on the coloration of the study organism and the color and placement of the elastomer, the marks fluoresce under ultraviolet (UV) light and are easily visible.

A VIE mark is non-toxic, light-weight, and based on the studies listed above, it is unlikely to impact survivorship. Because a single color kit can mark at least 700 turtle hatchlings and currently costs US $252, the cost is less than US $0.40 per mark. Placing multiple VIE marks in the front and hind legs, plastron, tail or toe webbing and using a combination of differently colored marks allows for marking schemes that identify the clutch of origin, year of hatching, or even individual hatchlings. The availability of several different colors of fluorescent elastomer is also useful for marking multiple clutches uniquely for future identification: Northwest Marine Technologies currently offers ten colors, six of which fluoresce under UV light. Below, we evaluate the use of VIE as a marking method for hatchling turtles. To our knowledge, VIE has not been previously used to mark hatchling turtles.

Methods

Before applying VIE to hatchling turtles, the method was tried on two captive adult turtles at Reptilia (a reptile zoo in Vaughan, Ontario). We marked one adult female Loggerhead Musk Turtle (*Sternotherus minor*) and one adult female Red-bellied Short-necked Turtle (*Emydura subglobosa*) with red VIE. Marks were injected subcutaneously on the ventral surface of the left hind leg using a sterile 0.3 cc syringe with a 29-gauge needle. Both animals were monitored on a daily basis by zoo staff and no ill effects were reported. The *E. subglobosa* was moved out of the zoo nine months after the mark was injected, at which time the mark was still clearly visible. The mark on the hind leg of the *S. minor* was clearly visible to the naked eye 18 months after injection. Under fluorescent light it was extremely bright and could not be mistaken for anything else (Fig. 1).

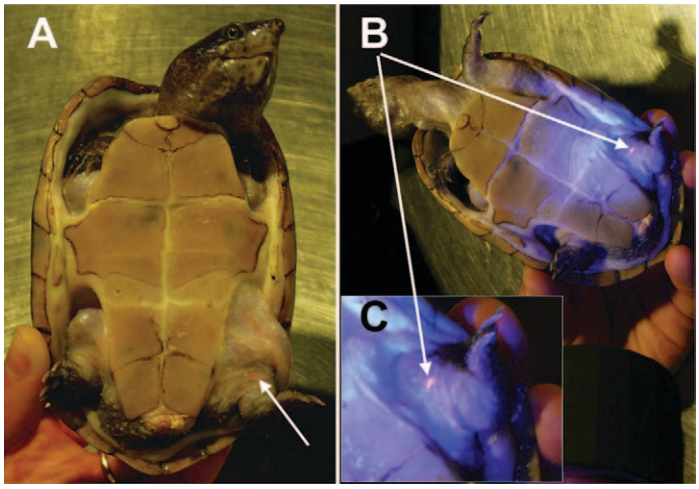

Fig. 1. Adult female Loggerhead Musk Turtle (*Sternotherus minor*) showing red visible implant elastomer mark in left hind leg (arrows). A) Mark is visible under standard room lighting or sunlight as a red dot. B) The mark fluoresces and is clearly visible under a hand-held ultraviolet light. C) Close-up of B.

We applied VIE marks to hatchling Snapping Turtles (*Chelydra serpentina*) during a research program conducted in part at the Pinery Provincial Park (Ontario, Canada) which involved *ex situ* incubation. After hatching, neonates were maintained in clean, humid tubs until they had completely absorbed their yolk sacs. They were then kept in shallow water with aquatic plants (*Elodea canadensis*) for shelter. Neonates (N = 301) were marked with red VIE within two days of hatching using a 0.3-cc syringe with a 29 or 30-gauge needle. Needles were cleaned with ethanol between applications. Enough elastomer was injected to leave a short line (approx. 2 mm long) or a small dot (approx. 1 mm diameter) beneath the skin in the underside of the hind leg or on the plastron.

Marked individuals were kept for a minimum of 24 h observation

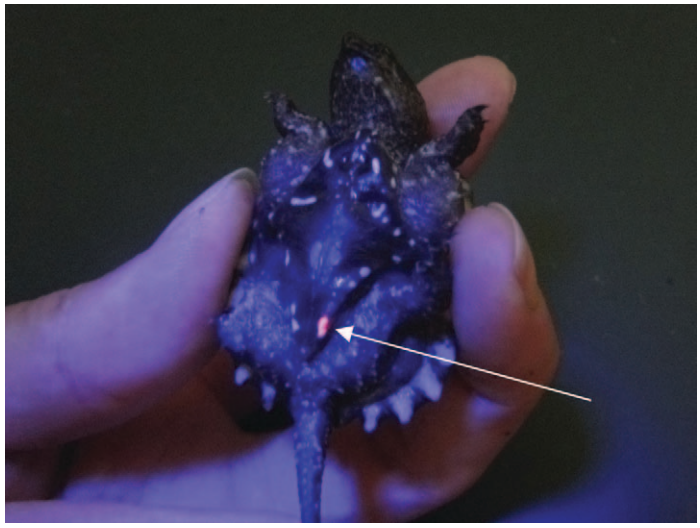

Fig. 2. Ventral view of a juvenile Snapping Turtle (*Chelydra serpentina*) found 11 months after hatching, marking and release. The red visible implant elastomer mark in the plastron (arrow) fluoresces under a handheld UV light.

(24–120 h; mean = 72 h) to monitor possible reactions to VIE marks. VIE marks may break apart, spread, move around under the skin, or be expelled (Heemeyer et al. 2007; Hutchens et al. 2008), so this period was also used to monitor for mark loss or changes in mark visibility or placement in the first few days post-marking. Hatchlings were released at the site of their original nest chamber within 24–72 h post-marking and allowed to enter the water themselves. In 2009, 301 hatchlings were marked and released. Eighty-four of these were released into the Pinery Provincial Park, where subsequent hatchling surveys were carried out, while the others were released at their original nest sites. The location of these releases varied, but all were sufficiently distant from the park (10–120 km) that dispersal back into the park was unlikely.

In 2009, two live embryos were found while opening unhatched eggs at the end of the season (unhatched eggs were opened a minimum of 30 days after the last successful hatch from the clutch). These embryos were kept in the same conditions as normally pipping hatchlings until they had absorbed their yolk sacs and both survived. By this point it was too late in the year to release them as frost had already set in. The hatchlings were marked and overwintered in a paludarium at the Pinery Provincial Park and both were released the following spring.

Results

No mortality or adverse reactions were observed following marking of hatchlings. No inflammation or tissue discoloration was observed around the marks. No evidence of mark breakdown, spread of VIE during curing, or mark expulsion was observed between marking and release and marks were clearly visible when fluoresced with a hand-held UV light (Northwest Marine Technology Inc., Shaw Is., Washington, USA) at the time of release. All hatchlings displayed normal behaviors when released. The two hatchlings which had overwintered in captivity grew quickly (as expected in captive turtles provided with high-quality food) and had doubled in straight-line carapace length by the time they were released in early May. The VIE marks in their hind legs were clearly visible under UV light at this time, despite their rapid growth.

During surveys for juvenile Snapping Turtles in Pinery Provincial Park from 23 June to 3 July 2010 (69.9 survey hours), we found 17 juveniles within the size range expected for hatchlings released in 2009. Four had VIE marks clearly visible in the left hind leg and two had been marked on the plastron (Fig. 2). None of the marks in the leg had broken down, but one of the plastral marks appeared to have split into several pieces, possibly due to the turtle's growth. Despite changing in shape, the plastral mark was still clearly visible.

It is possible that juveniles found in 2010 that did not have visible VIE marks were in fact released turtles which had lost their marks. We are currently incorporating Decimal Coded Wire Tags (Northwest Marine Technology Inc.) into our mark-recapture study to allow for more accurate estimations of the rate of VIE mark loss in turtles and we are not able to estimate exact rates of mark loss at this time. However, in our experience it would be unlikely to find only released juveniles during our surveys.

Fluorescent food for thought.—Researchers who plan to use VIE to mark hatchling turtles should consider the following in their experimental design. First, the rate of VIE mark loss in turtle hatchlings must be more accurately quantified and may differ among species. Second, it is possible that the rapid growth rate of juvenile turtles will cause the marks to be overgrown and obscured. Although the marks remained visible in both the two hatchlings that overwintered in captivity (which doubled in size), and although they were visible after ten months in recaptured hatchlings which had overwintered naturally, we have no way to accurately gauge the rate of mark loss at this time. Both of these concerns can be addressed by applying multiple marks to each hatchling (study in progress).

If mark loss were high in the first few days post-marking, application of Liquid Bandaid over the injection site might increase mark retention. Liquid Bandaid or cyanoacrylate glues are commonly used to increase PIT tag retention in snakes (e.g., Koons et al. 2009) and Liquid Bandaid has been suggested as a method of increasing VIE retention in snakes (Hutchens et al. 2008). However, we did not experience any mark loss during the first few days after marking. Therefore, we chose not to apply Liquid Bandaid to the injection site in order to avoid introducing further chemicals onto the hatchlings' skin and to avoid sealing potential pathogens into the healing injection sites.

In summary, VIE marks provide a simple, cost-effective way to quickly and non-harmfully mark large numbers of turtle hatchlings for mark-recapture studies, including evaluation of head-starting methods. Marks made with VIE are completely unambiguous; however, quantitative analyses of the rate of mark loss are still required. Marked turtles should be easily identifiable for at least the first year and if recapture rates are very low (or nonexistent), the VIE marks do not represent a significant loss of resources.

Acknowledgments.—Funding was provided by a CGS grant from the National Science and Research Council of Canada. This work was approved by the Animal Care Committee of the Royal Ontario Museum, the Ontario Ministry of Natural Resources, and Ontario Parks. We thank Mary-Elizabeth Murray, Eric Davy, and Kum C. Shim for assisting with nest collection and hatchling surveys. We also thank Stephanie Donaldson and the Friends of Rondeau for generously providing various accommodations in 2009; the Friends of Pinery Park for assistance during 2010; the staff of Ontario Parks for logistical support; and Andre Ngo, Lee Parker, and Reptilia Reptile Zoo for permission to test this method on captive turtles.

In cranial morphometrics, an effective way of obtaining data for analyses is by using photographs or drawings. With an average digital camera, computer and software it is now possible to extract extensive information on size, shape, location, surface area, and color. Existing photographs or drawings, however, may not always be suitable for metric comparisons because of optical distortion, light conditions, the background used, or inconsistency in type and position of the camera or skull (Friess 2003). Ideally an applicable standardized method would be used in all photo-documentation and photographic research. For practical purposes, however, a proper and complete documentation of exact methods used would allow other authors to use the information or convert the acquired data to match theirs.

We describe and discuss a method, used successfully in previous morphological research on crocodile skulls (Pearcy, unpubl. data), with regard to applicability and effectiveness. Crocodilian skull morphometric studies are becoming more frequent (e.g., Pierce et al. 2008; Piras et al. 2009; Sadleir and Makovicky 2008), and therefore there is need for such methods' description. Object orientation with respect to the camera, optical distortion, and materials used are discussed.

General Setup and Materials

Skulls were placed on a floor using a black towel as background. We used a Panasonic Lumix DMC-FX107 digital camera set to intelligent AUTO mode, 3072 x 2304 pixels, JPEG/Exif format. The camera was screwed on an adjustable aluminum tripod placed on the floor positioned directly over the skull. For each picture the camera was set to automatic-mode with a two-second timer to prevent movement blur from pressing the shutter button. The lens range was 28–102 mm and aperture range F2.8–F5.6. The grid in display option enabled a non-essential but convenient way of lining up specimens within the field of view.

The tripod's center column and head were inverted, so the camera on the saddle plate was centered between the legs of the tripod directly perpendicular to and facing the skull. Because crocodile skulls have a wide range of height, distance from specimens had to vary arbitrarily from 40–120 cm for convenience.

Orientation of Subject and Camera

Dorsal view cranium.—This view is most commonly used for comparative studies between crocodilian species (Fig. 1).

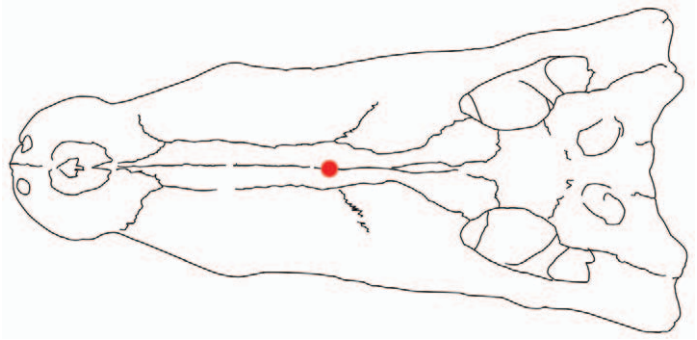

FIG. 1. Dorsal view of the cranium. The red dot shows the center point along the midline of the skull and the focus point of the camera.

The cranium rests upon its pterygoid flanges and front teeth or alveolus and is leveled along the midline from cranial table to tip of snout. Where necessary, the skulls were also leveled along the cranial table width-wise. Black towels were rolled up into appropriate thicknesses and placed under skulls to raise them to the desired height. The focus point (red dot) was on the center of the midline.

Ventral view cranium.—For this view of the skull, the tip of the snout posterior to the premaxillary tooth row is made level to the back of the skull along its midline (Fig. 2). Focus point remains the same as that of the dorsal view of the cranium.

Occipital view.—For this shot, the skull is leveled along its midline as it was for the dorsal view (Fig. 3 a–b). The lens focus point is the tip of the vertebral condyle.

Lateral view cranium.—The skull is laid flat without leveling, with its lateral axis perpendicular to the view of the camera (Fig. 4a). In this way, the snout and posterior portion of the skull can be compared. The focus point is halfway between the tip of snout and the back of cranium (Fig. 4b).

Dorsal/Ventral view lower jaw.—This view can be used for the study of the mandibular symphysis and other basic jaw studies (Fig. 5). For the dorsal view, the lower jaw is leveled from the inside of the front teeth to the inside of the back of the jaw, resting on the mandibular ramus indentions. For the ventral view, the leveling remains from the tip of snout to the back of jaw. Again, the focus point is the center of a virtual midline along the length between the mandibular symphysis and the back of the jaw.

DISCUSSION

In this discussion we will elaborate on the methods used and where applicable consider other options and improvement.

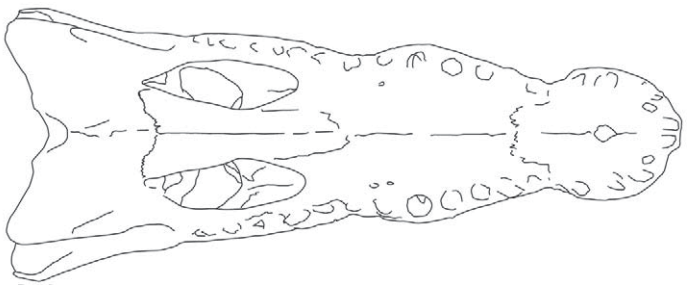

FIG. 2. Ventral view of the crocodile skull.

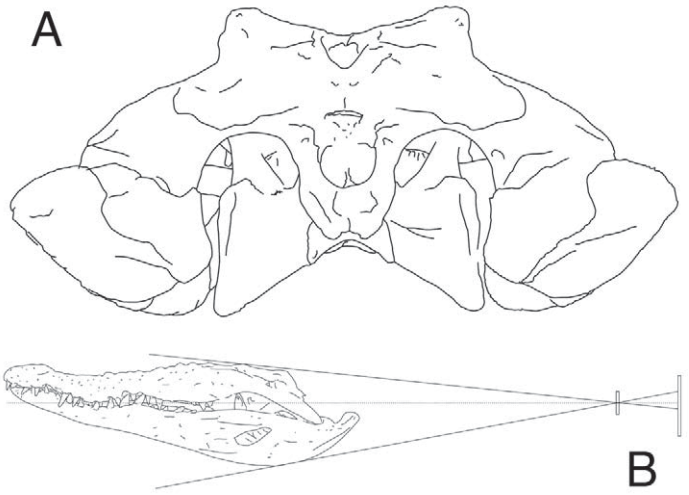

FIG. 3. Occipital view of the cranium (a) and the leveling of the skull for the focus point (b).

Generally, methods chosen are based on the intended measurements of study. We state, however, that in many situations using a general standardized method when photographing crocodile skulls would optimize the use of a photograph and thus be preferable. The methods can, of course, be adapted for photographing dorsoventral topography of other large tetrapods.

Leveling a skull in general makes for a repeatable method. The lifting of the skull in dorsal perspective allows for the view of the front end of the tip of the snout instead of just the top end of the snout. Error from not leveling the skull is dependent upon a skull's size. A *Crocodylus acutus* with a real maximum cranial length of 80 cm will appear to be about 2.5 cm shorter in any picture when not leveled; the same measurement on a *Crocodylus johnstoni* would only be off by about 1 cm. Not leveling the skull in ventral view, a technique applied often, is obviously more convenient and would show more of the skull; however, this makes extracting measurements from pictures nearly impossible due to depth differences. Positioning of the skull in occipital view is, as far as we are concerned, a matter of individual choice. Depth differences are relatively large, thus this view is not normally used. We chose to level the skull to have a better view of the tip of the vertebral condyle as a reference point. Artificially adapting the position of the skull when resting on a horizontal surface in side

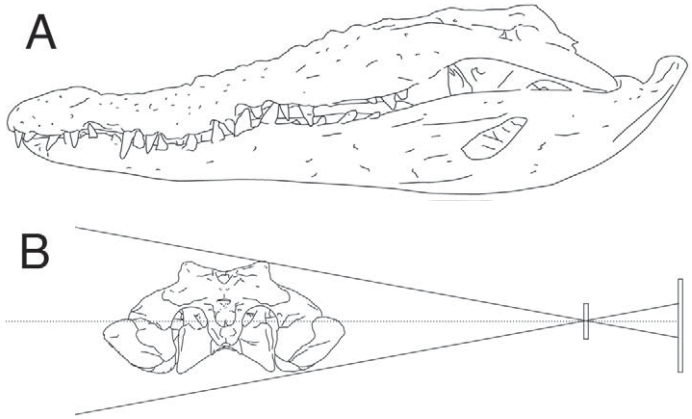

FIG. 4. Lateral view of the skull (a) and the aim of the camera (b).

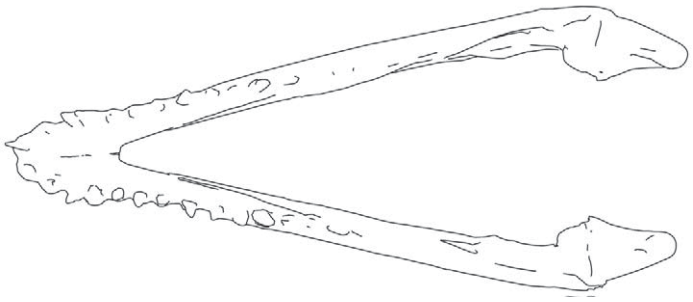

FIG. 5. The lower jaws of a crocodile skull. While this diagram is from the dorsal view, the ventral view is similar.

view would expose more of the lower jaw and less of the upper, although the effect is very minimal due to the flattened skull of a crocodile, rendering such actions virtually useless. In dorsal view of the lower jaw, we leveled the jaw in a repeatable way. Apart from enhancing accuracy of later distance measurements, this action also exposes an often researched subject—the teeth and their sockets—more evenly.

Any optical lens leads to distortion of the absolute and relative dimensions of an object like a skull. The outer edge of the skull will be invisible in a central projection, affecting absolute dimensions. Furthermore, objects that are closer to the focal point will appear relatively bigger than they are compared to portions that are further away, thereby affecting the proportions of the object. Practically speaking, taking a picture of a cranium with a distance of one meter results in a distortion of a maximum of 7.5% (Jacobshagen et al. 1988) and so-called barrel or pincushion distortion is negligible using everyday lenses. Most distortions can be avoided by applying stereophotographic techniques. Another commonly used technique relies on resorting to reference objects–a ruler for instance–from which sizes can be related to later, but the reference object must be at the same height as the surface being photographed in order to minimize error. We believe, however, that in the interest of applicability, increasing the distance between the camera and the object, which significantly reduces the photographic error, or resorting to mathematical solutions like a Generalized Procrustes Analysis (Bookstein 1996; Rohlf 1999) as we did, is a more preferable solution. Also, in many situations, adapting one's methods to render optical error irrelevant is the best solution.

Backgrounds, for most purposes, must be in contrast to the subject as much as possible. For the generally white skulls, we used a black towel. Contrast decreases ambiguity between skull and background, and darker backgrounds will reduce the number of artifacts caused by shadows or reflection. Both lead to more precise definition. However, in some situations using a background color that is unlikely to be present in the subject might be worth considering, as software would then be able to filter this color independent of the subject color.

With the accuracy of distance measurements roughly increasing with the square root of pixel depth, we consider a 7 Megapixel camera, giving an estimated error of 0.05 cm on an 80 cm specimen, about the minimum for most applications with crocodile skulls. The tripod may not always be a necessity. It does, however, lend stabilization to the camera, especially important in self-timed shots.

Not all studies have the funding to use stereographic techniques or even CT-scans, which would reduce distortion completely, and allow for a comprehensive assessment of measurements. The methods presented here are cost-effective, while reducing distortion. Museums and conservation groups can follow these methods for their databases in order to have a comparable method, repeatable by anyone with a digital camera and material for a background. If not applied, at least the description presented herein should serve as an example to the extent required to allow other researchers to convert their data into comparable material.

Acknowledgments.—We would like to acknowledge Franklin Ross for input and advice. The Amsterdam Zoological Museum, Royal Belgian Institute of Natural Sciences, Naturalis, Paris MNHN, and Senckenberg Naturmuseum kindly allowed us access to their collections.

Marking individual animals in wildlife studies is essential and plays a vital role in furthering our knowledge of animal populations. Mark and recapture studies delineate ranges and migratory movement patterns, help identify which populations use feeding and breeding grounds, and can contribute to vital rates where animals can be encountered across time during breeding events. Marine turtle studies also have benefited from marking of animals. External tags have long been used to mark individual nesting turtles, juvenile and adult turtles in benthic, oceanic and neritic foraging habitats (Godley et al 2003; Limpus et al. 2009; Mortimer and Carr 1987; Schmid 1998). However, some external tags have been found to cause harm or reduce the survival of an individual (Nichols et al. 1998). In addition, external tag loss is common and decreases the rate at which previously tagged individuals are identified (Balazs 1982; Bjorndal et al. 1996; Henwood 1986; Limpus 1992). Consequently, in recent years, use of Passive Integrated Transponder (PIT) tags, also termed Radio Frequency Identification tags, has increased (Balazs 1999; Broderick and Godley 1999). A PIT tag is a tiny electronic microchip encased in a glass capsule that is inserted under the skin or into muscle. It is passive until interrogated with an external tag reader, and then it briefly transmits a unique identification number to a receiver. Studies examining the feasibility and ease of PIT tag use determined that PIT tags have a much greater retention rate than external tags and increase the reliability of re-identifying tagged animals (Balazs 1999; Braun-McNeill et al. 2003; Dutton and McDonald 1994) when tag readers are on hand. Due to the subcutaneous placement of PIT tags, internal complications that result after insertion may occur. To date, surprisingly few studies have examined this aspect of PIT tag use in seaturtles (van Dam and Diez 1999).

The negative effects of PIT tags on wild animals are often difficult to determine. Once seaturtles have been tagged, they are released (usually immediately) back into the environment where they spend most of their lives beyond the reach of researchers. PIT tags are designed to minimize internal complications through the use of a glass protective coating. Although this glass casing serves to both protect the electronic components and prevent tissue irritation (Gibbons and Andrews 2004), there are some reports of visible infection and irritation at the PIT tag injection site despite proper use of disinfecting techniques during insertion in marine turtles (Dutton and McDonald 1994), manatees (Wright et al. 1998), and fish (McKenzie et al. 2006). Along the Atlantic Coast of the U.S., reports of tag-related infection and joint injuries appear in stranding data (New England Aquarium [NEAq], unpubl. data). While there are many advantages to using PIT tags (Balazs 1999; Gibbons and Andrews 2004), recognizing risks and advantages associated with different tagging sites will enhance the quality of studies relying on this marking method. As all seaturtle species are considered imperiled (IUCN listing varies with population), there remains a need to recognize impacts on the health, physiology, and ultimately the survival of PIT-tagged turtles.

The use of PIT tags is usually benign. When tags are placed into muscle, the cutting edge of the applicator needle makes a small circular cut that extends to the depth of the injection. The tags induce encapsulation by fibrous connective tissue, which stabilizes their placement. Encapsulation is most rapid and effective in highly vascular, resilient tissue such as muscle. While the injection causes a small cut in the muscle, it is the responses by fibroblasts and muscle cells to this minor damage that result in largely stable tags. When the tags do not stay where placed, they can be expelled from the body or migrate internally causing inflammation and damage and opening a route to infection. PIT tag movement has been documented in bats (Barnard 1989), young birds (turkey poults; Jackson and Bunger 1993), reptiles and amphibians (Camper and Dixon 1988; Keck 1994), and fish (Baras et al. 2000, Gheorghiu et al. 2010). Baras et al. (2000) found that PIT tags injected into perch migrated ventrally over time. PIT tag movement also has been reported in Hawksbill (*Eretmochelys imbricata*) seaturtles (van Dam and Diez 1999). Not only can the migration of the tag reduce the re-identification accuracy, it may cause injury. The risk of complications can be minimized by the location and method of tag placement (Germano and Williams 1993; Gibbons and Andrews 2004; Jackson and Bunger 1993). In cheloniids, PIT tags usually are inserted via injection using an applicator fitted with a sterile 12-gauge needle. The most common PIT tagging sites used in the U.S. Atlantic and Gulf of Mexico coasts are subcutaneously along the trailing side of the flipper blade (adjacent to the radius and ulna, wrist, and/or metacarpals; Fig. 1) or, for large species (*Dermochelys* and some cheloniids), in anterior shoulder muscles medial to the arm. Additionally, more than 9000 Kemp's Ridley (*Lepidochelys kempii*), Loggerhead (*Caretta caretta*), Green (*Chelonia mydas*) and Hawksbill turtles were released with PIT tags inserted into the ventrally located pectoral muscles (Fontaine et al. 1987). To date,

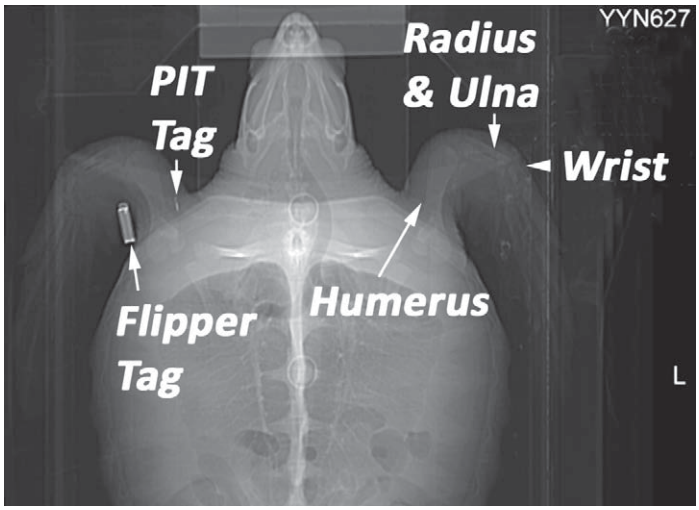

FIG. 1. The overall skeletal anatomy of the marine turtle forelimb and shoulder and several tags are shown in this two-dimensional dorsoventral view CT scan. The forelimb skeletal elements of relevance to this study are labeled. The small PIT tag is in the triceps muscle, an external flipper tag in attached to the trailing edge of the flipper. The light circles at mid-body and the base of the neck, as well as the lighter rectangle at the anterior head, are parts of the scanner's table.

studies of PIT tag placement in seaturtles focus on locations that maximize tag reader reception (Epperly et al. 2008).

In this study, we tested the null hypotheses that PIT tag movement does not differ between species or between two locations in the forelimb: the trailing side of the flipper blade (defined as the proximal manus and antebrachium) and the triceps muscle complex of the upper arm (the brachium). We assess whether PIT tags migrated once placed at the two locations in clinically healthy juvenile Loggerhead and Kemp's Ridley turtles. We report PIT tag movement in both species at the two tagging sites and recommend adoption of the triceps muscle site in seaturtle studies to reduce tag migration and potential complications.

Turtles and Maintenance.—The Loggerhead turtles for this study were wild-caught as hatchlings from marked nests in Clearwater, Florida, USA (emerged from nests 27 August 2000); Kemp's Ridley turtles originated as hatchlings from relocated nests incubated on the beach at Rancho Nuevo, Mexico (emerged 16 August 2000). The turtles were reared in captivity at the National Marine Fisheries Science (NMFS) Sea Turtle Facility in Galveston, Texas, USA. All turtles were juveniles and were similar in size (Loggerhead turtles, N = 21, 31.4–33.6 cm straight carapace length (SCL), mean ± SD = 32.6 ± 0.6 cm; 3.3–4.8 kg, mean = 4.0 ± 0.4 kg; Kemp's Ridley turtles, N = 24, 27.0–30.2 cm SCL, mean = 29.1 ± 0.7 cm; mean = 3.4 ± 2.0 kg). Turtles were held in individual rearing containers in a common raceway tank filled with seawater. Raceways were drained and re-filled with fresh seawater three times/week (described in detail elsewhere, Higgins 2003). Kemp's Ridley turtles were maintained in the Galveston facility prior to and for the duration of the study. Loggerhead turtles were maintained at the Galveston facility for two months, taken to Panama City, Florida and placed under semi-wild conditions for 30 days in communal, large open seawater pens. There they were used for fishing equipment research unrelated to this study, then returned to Galveston. In the Panama City pens, turtles were able to swim more vigorously and interact, potentially challenging the tags and the tag sites beyond what they might experience at the Galveston facility.

PIT Tag Placement and Tag Migration Assessment.—All turtles were tagged in the same forelimb, at both tagging locations, on the same day. Tagging sites were cleaned with 70% isopropyl alcohol and povidone iodine swabs, and then one PIT Tag (Model TX1406L, Destron-Fearing, 12.50 mm L x 2.07 mm diam) was inserted at each site via a pre-loaded sterile 12-gauge needle. One tag was placed deep to the dorsal skin adjacent to the fifth metacarpal and carpal bones on the caudal (postaxial) side of the flipper (Fig. 2a), while the other was placed within the cranial part of the triceps muscle complex in the upper arm on the same side of the turtle (Figs. 2b). Each tag site was sealed with a drop of surgical cement (VetBond™; 3M™, St. Paul, Minnesota) to minimize the chances of tag loss and infection.

Initial MRI scans of the entire flipper were taken shortly after insertion (1 April 2002 for Kemp's Ridley turtles; 2 April 2002 for Loggerheads). Second MRI scans were taken at 104–106

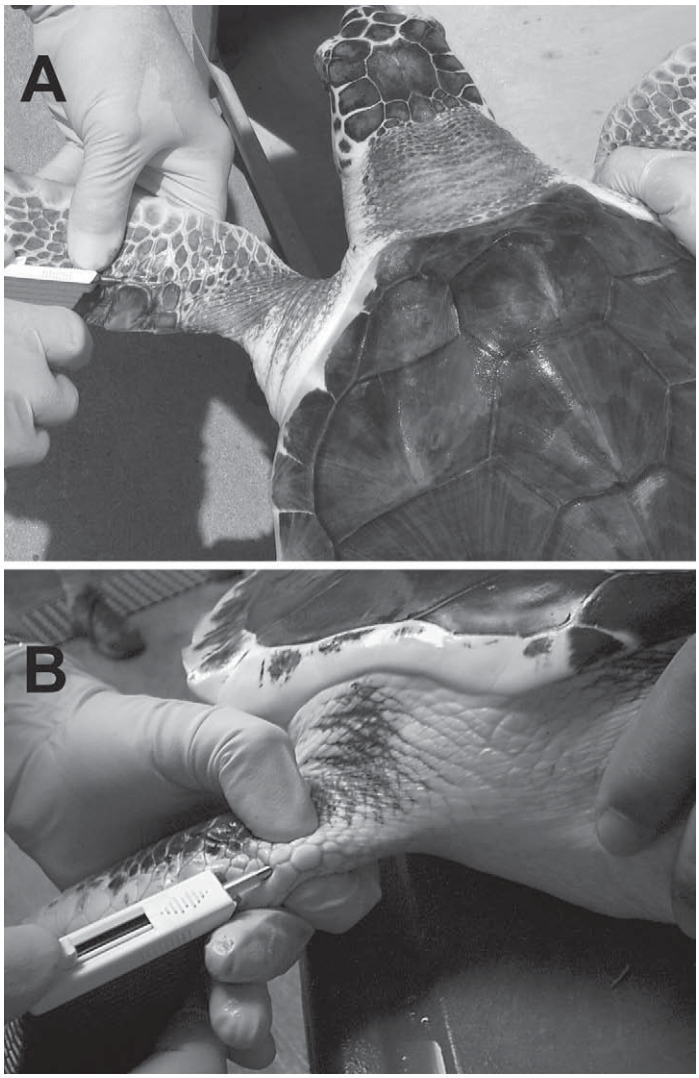

FIG. 2. (A) PIT tag insertion into trailing edge of flipper blade parallel to the fifth metacarpal and postaxial carpal bones. (B) PIT tag insertion in triceps muscle complex of the upper arm showing the method of manipulating the muscle and allowing the tagger to palpate the insertion of the tagging needle and tag.

days (16 July 2002 for Loggerheads, and 17 July 2002 for Kemp's Ridleys). Each turtle was anesthetized (0.15 mg/kg meditomidine, 5 mg/kg ketamine) administered IV in a cervical sinus (external jugular vein). Turtles were placed in ventral recumbency with the flipper positioned alongside the body in a standardized position, flippers were flexed so they rested along the lateral carapace with the blade's long-axis aligned with the scanner table axis, and flippers were held in place with Vet Wrap™ Bandaging Tape (3M™, St. Paul, Minnesota). Scans were taken in dorsoventral and axial planes so that the three-dimensional positions of the skin, muscles, tag, and bones could be visualized. After the scans, the anesthesia was reversed with 0.75 mg atipamezole administered IV in the external jugular vein.

TABLE 1. The fate of PIT tags in (A) Loggerhead (N = 21) and (B) Kemp's Ridley (N = 24) seaturtles over 104–106 days, showing the contingency tables for each species.

A. Loggerhead		Flipper blade		
		No movement	Movement	Row totals
Triceps muscle	No movement	11	7	18
	Movement	1	2	3
	Column totals	12	9	21
B. Kemp's Ridley		**Flipper blade**		
		No movement	Movement	Row totals
Triceps muscle	No movement	15	9	24
	Movement	0	0	0
	Column totals	15	9	24

The metal in each PIT tag produced a signal-void of characteristic size and shape. The maximum size of each signal-void (hereafter referred to as the PIT tag) was used to determine tag position. Each scan was evaluated to determine the distance of the PIT tag's longest axis end to nearest joint and/or bone (Fig. 3); the structure used as the landmark varied among individuals, but was consistent within an individual. Distances were measured using eFilm Lite v.2.1 (Merge Technologies Inc. 2005) and compared. Humerus length (from midpoint of the head to distal-most point, the radial facet) was also measured and compared between first and second scans to account for growth during the study. PIT tags were categorized as having moved or not moved. If the distance of the PIT tag void to the nearest joint and/or bone was greater than the increase in humerus length ± resolution error (defined as > 0.2 cm), the tag was considered to have moved. If the distance was not greater, the tag was assumed to have not moved. In the absence of three-dimensional reconstructions and scan intervals greater than the one we used, we could not measure actual paths traveled for each tag.

Statistical Analysis.—A 2 x 2 contingency table and McNemar's test for significance of changes, adjusted with Williams' correction, was used to assess whether PIT tag movement in one location was independent of movement in the second location. SAS v.9.2 was used to generate all statistics (SAS Institute, Inc. 2009).

Results.—In Loggerheads, three of the 21 tags (14%) placed in the triceps muscle complex migrated, while 9 tags (43%) placed in flipper blades displayed movement (Table 1). However, in the

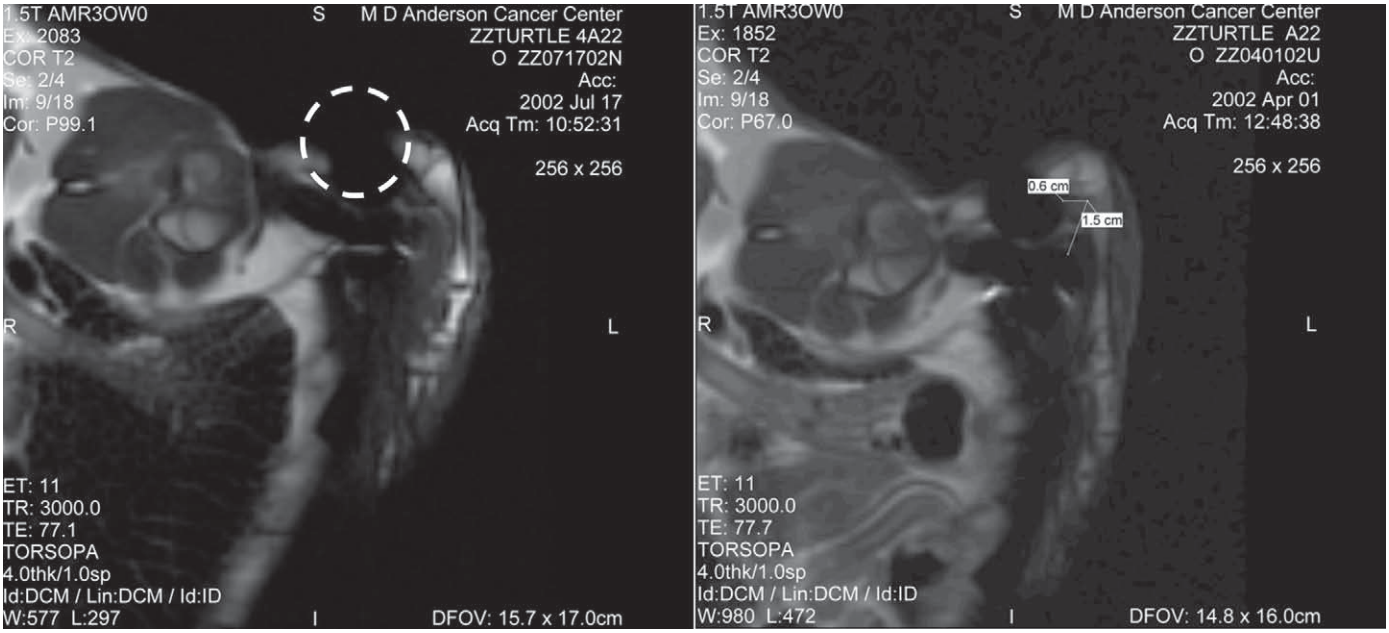

FIG. 3. (A) A dorsoventral plane MRI scan of the left turtle flipper and shoulder. The white dashed circle indicates a signal-void produced from PIT tag in the triceps during the MRI scans. The bone and fat are light colored, muscle is gray, and air in the lung is black. (B) MRI scan of a left turtle flipper with measurements taken from the long axes of the two signal-voids to the nearest joint. Humerus length (from midpoint of the head to the distal-most point, the radial facet) was also measured and compared between first and second scans to account for growth during the study.

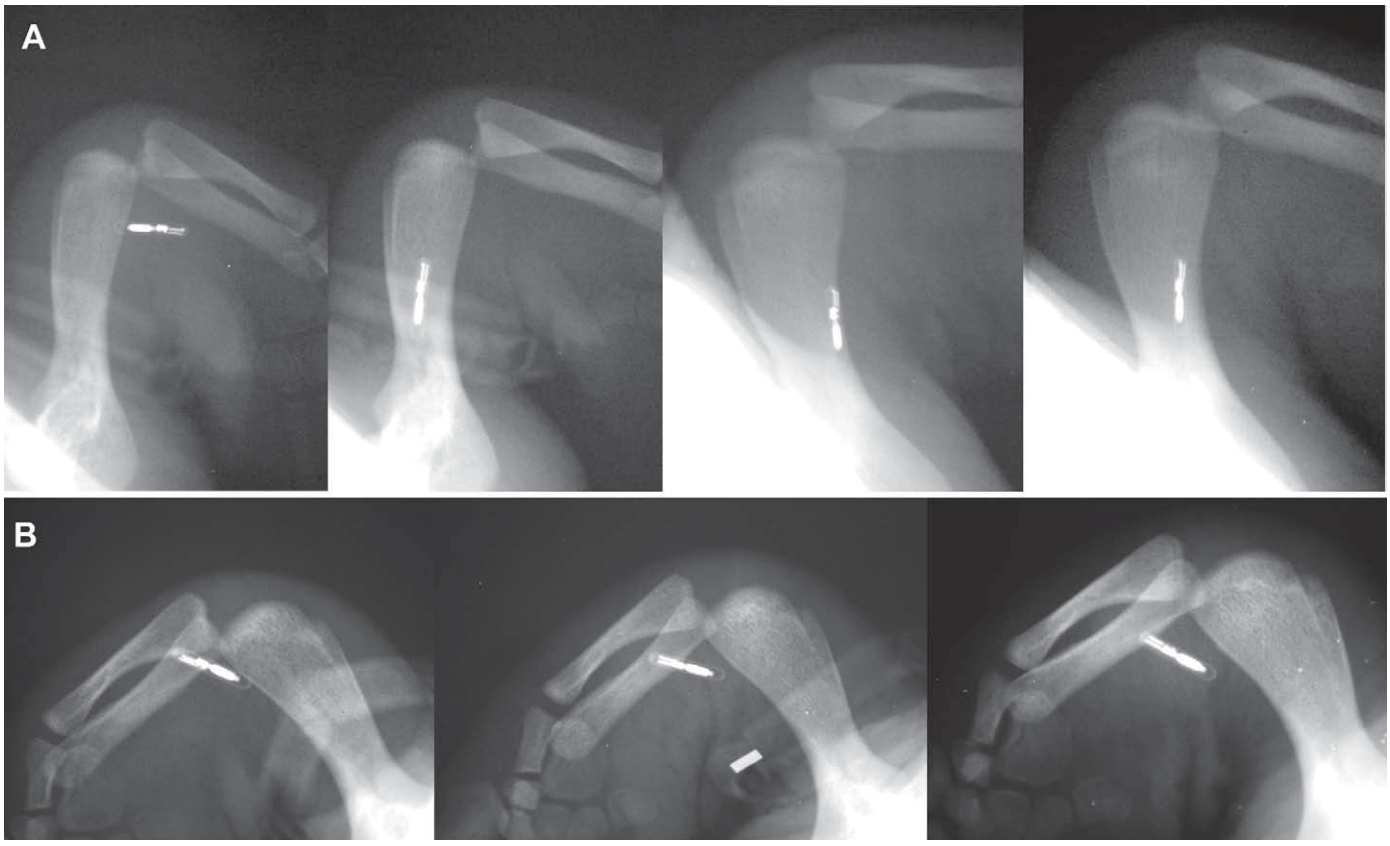

FIG. 4. (A). Migration of a PIT Tag in the right flipper of a cold-stunned Kemp's Ridley (ID No. 99-831). The top four images span 253 days. The greatest proximal movement occurred between the initial radiograph (28 days after the tag was inserted) and the second, a period of 58 days. Subsequent movement was more circumferential from the second to last images (from 58 days to 168 days to 253 days). While the tag migration was quite obvious, the site did not become infected, most likely due to several courses of systemic antibiotics administered to treat other health issues. (B) Botton row: radiographs taken of a second Kemp's Ridley (ID No. 99-842), also show PIT tag migration, however with less drastic movement than in 4A. While the migration of the tag appears shorter in distance, the impact to the animal's health was more significant. The PIT tag was initially placed in the anterior dorsal part of the left front flipper blade on 21 November 1999. The radiographs (left to right) were after two days, 73 days, and 89 days. The tag site became severely infected requiring surgical removal of the tag. The animal was treated topically at the wound site and with systemic antibiotics for several months following tag removal.

majority of cases (62%), both of an animal's tags performed similarly. We rejected the hypothesis that movement at the two sites was the same in Loggerheads ($S_{adj} = 4.2353$, $p < 0.05$). The maximum net tag migration that we could measure, in Loggerheads, was 5.2 cm in the flipper blade and 1.3 cm in the triceps muscle complex. In Kemp's Ridley turtles, none of the 24 tags placed in the triceps muscle complex migrated, whereas 9 of the tags (38%) placed in the flipper blade had moved (Table 1); the maximum net distance moved in the flipper blade of Kemp's Ridleys was 2.2 cm. The marginal proportions (e.g., the cases where both tags in a turtle did not have the same result) were identical (38%) in the two species (Table 1). In no case was infection noted.

Discussion.—We determined that the forelimb tagging locations used in two species of marine turtles differ in their tendency for PIT tags to migrate. Tag migration is an important factor to consider in minimizing risks to the turtles. Movement occurred more often in PIT tags that were inserted subcutaneously in the flipper blade, suggesting that this location can be problematic. The tag stability at one site was not related to tag performance at the other site. Our results are consistent with the tag loss results that vanDam and Diez (1999) found when tags were placed subcutaneously in Hawksbill turtles. Despite the short time frame of this project and the lack of three-dimensional reconstructions, we were able to detect migration by PIT tags in the subcutaneous hypodermal layer, which is rich in collagenous and elastic connective tissues. This site, adjacent to the ulnare, pisiform (carpals), and fifth digit metacarpal, has relatively thick, keratinous skin overlying a connective tissue network with little or no muscle tissue. The muscles of the manus are very reduced in this part of the flipper and may be missed entirely during PIT tag application. In contrast, PIT tags inserted into the triceps muscle complex with the muscle pinched outward (cranially or dorsally) during tag placement (Fig. 2b) clearly are embedded in muscle tissue. Muscle, a metabolically more active tissue, is more likely to encapsulate the tag quickly. While PIT tags may become encapsulated and stabilized in connective tissue, they appear to be more stable when placed in muscle. We presume that the tags placed in the shoulder muscles of large turtles as well as those placed in the hind flipper muscle (Balazs, unpubl. data), a tagging site used in some Pacific studies, are probably stable, however, direct comparisons with the hind flipper site were beyond the scope of this study.

The possibility exists that movement of the tag may occur well beyond the time frame of this study (104–106 days). It is possible

that tag movement or loss may be greater in wild animals than those in captivity (Thomas 2006) associated with their potential exposure to more varied physical stressors, although we did not observe such in Loggerheads that were allowed 30 days of swimming in open pens (compared with Kemp's Ridleys that were maintained in tanks). PIT tag movement may also increase with the size of an animal (Gibbons and Andrews 2004), indicating that the tag movement measured in this study may be less than what might occur in larger juvenile or adult turtles.

In some cases, movement of a PIT tag may be detrimental to seaturtle health and survival. Several cases of PIT tag migration in the flippers of cold-stunned Kemp's Ridley turtles were documented by the NEAq while the animals were undergoing rehabilitation. In November 1999, more than 277 seaturtles stranded along the shores of Cape Cod Bay (Massachusetts, USA) during a large cold-stunning event. A total of 156 were recovered alive (Still et al. 2002) and transported to the NEAq for rehabilitation. Due to the overwhelming volume of cases admitted into the NEAq seaturtle clinic, turtles were rapidly transported to secondary facilities for rehabilitation. Many turtles were PIT tagged in the dorsal and cranial flipper blades prior to transport (N = 103 Kemp's Ridleys), while others were tagged prior to release. Tag migration was noted via radiographs of several turtles (Fig. 4). At least eight of those 103 turtles developed localized infection associated with the PIT tag, and surgical removal of the tag was required. It is likely that this number under-represents the true number of infections, due to the difficulty in following the clinical outcome of large numbers of turtles after relocation to multiple institutions. At least one of these turtles developed significant osteomyelitis of the humerus, radium, and ulna. While osteomyelitis and joint mobility issues are common in cold-stunned turtles (Wyneken et al. 2006), the proximity of the PIT tag to the sites of infections suggested further assessment of PIT tagging location was warranted. Infections of the skeleton and primary locomotor structures are likely to decrease survival probability.

Because our study tested the tendency of PIT tags to migrate in clinically normal turtles (both Kemp's Ridley and Loggerhead turtles) we were able to confirm that tags placed in the flipper blade may migrate even in the absence of infection or cold stress. Similarly, tag migration was observed in penguins both in the presence and absence of microbial growth around the tag and infection (Clarke and Kerry 1998).

It is likely that when physiologically stressed, such as by hypothermia, immune function decreases (reviewed by Jacobson 2007). Thus cold-stunned or otherwise stressed turtles may be at increased risk of infection in the PIT tag site (Baras et al. 2000). Infection and irritation have been reported in PIT tagged leatherback turtles as well (Dutton and McDonald 1994).

Studies of PIT tag placement in the skin of manatees (*Trichechus manatus latirostris*) showed that when the skin is thick, a plug of skin can be driven internally in front of the tag during the injection, increasing the risk of infection. This may, in turn, increase tag movement or rejection (Lambooij et al. 1995; Wright et al.1998).

PIT tags can also be expelled from animals, depending on where the tag is placed (Elbin and Burger 1994; Fontaine et al. 1987; Gibbons and Andrews 2004). Zimmerman and Welsh (2008) studied the placement of PIT tags in American Eels (*Anguilla rostrata*) and found that tag retention varied according to tag location, with the highest retention rates in tags placed into musculature. PIT tags placed in penguins and monitored over several years showed that tag movement can be substantial (> 5 cm; Clarke and Kerry 1998). We observed less movement in PIT tags placed into seaturtle triceps muscle than the trailing aspect of the flipper blade, thus its use may minimize the potential for tag migration, infection and loss. Risk of PIT tag movement and/or infection caused by PIT tags in seaturtles can be mitigated by combining standard skin cleaning with an antiseptic solution prior to application, the use of a sterile applicator and tag, and placement of the tag in a stable location where the keratinous skin layer is thin and the tag is most likely to be placed in muscle. In addition, the accuracy of seaturtle mark-recapture studies will increase because once placed in the triceps muscle, the tag is less likely to move; it remains within readable distance because of the location and size of the muscle, and should increase recognized recaptures.

There may be other advantages to placing the PIT tags into the triceps muscle over the flipper blade. The triceps muscle complex provides some soft tissue protection and so may decrease the likelihood of a tag failure due to shattering of the glass casing. When the glass encasing a PIT tag's electronics is broken, the transponder fails (Camper and Dixon 1988; Lambooij et al. 1995) and tags can migrate, breaking through skin (Germano and Williams 1993). Camper and Dixon (1988) report tag breakage and malfunction due to aggressive encounters between lizards. While we found no incidence of PIT tag failure in seaturtle flipper blades during this study, lack of "padding" in the flipper blade does little to minimize the risk of tag breakage.

While PIT tag location, consistency, and reliability are important aspects of any mark-recapture study, there has been relatively limited consideration of the efficacy of tag placement in seaturtles except for turtle size (Fontaine et al. 1987) and accommodating the limits of tag readers (Epperly et al. 2008). Consideration of tag migration risk in seaturtles is examined for the first time here.

The use of PIT tags is an integral part of much herpetological research. PIT tag use is clearly essential in understanding vertebrate populations worldwide and has greatly increased the reliability and ease of re-identification of individuals. PIT tag use is bolstering our knowledge of seaturtle populations, at sea and on land. Their use in seaturtles has increased recapture rates, which has improved understanding of turtle movements, growth rates, habitat use, nesting success, internesting intervals, migration and numerous other life-history attributes. In addition, the use of PIT tags has eliminated the need to mark turtles using tattooing, drilling or carapace scarring (Affronte and Scaravelli 2002; Hendrickson and Henrickson 1981). Our results support avoiding the flipper blade and applying tags in the triceps to minimize risks of compromising the well-being of the tagged animal.

Cromeens, J. Hazle, C. Innis, S. LeBlanc Marco, R. Price, J. Rindfleish, F. L. Steinberg, MD, P. Sforca, D. Wilke, K. Wright, and the NOAA Fisheries Sea Turtle Facility staff at Galveston. A. Chester, C. Innis, M. Salmon, and anonymous reviewers provided valuable comments on this manuscript. This work was conducted under U.S. Fish and Wildlife Ser-

vice Endangered Species Act Section 10a(1)a Scientific Research Permit #TE-676379-4 and complied with all institutional animal care guidelines. The Florida Atlantic University (FAU) IACUC determined that the study is in compliance with IACUC guidelines; administratively it does not receive an approval number because FAU personnel worked with the data files alone, not the animals. The methods used were consistent with those the IACUC would approve had the animal part of the study been done by FAU personnel. At the time, the NMFS did not issue IACUC approvals, but always complied with USFWS and State of Florida requirements for holding seaturtles. J. Flanagan, DVM ensured that best practices were followed. All authors participated in one or more aspects of this study and edited the manuscript.

The fungal pathogen *Batrachochytrium dendrobatidis* (*Bd*) is implicated in the decline of worldwide amphibian populations (Berger et al. 1999), with new occurrences of the fungus being constantly reported (e.g., recent issues of *Herpetological Review*). Whereas the fungus has been detected in numerous locations, it is considered an invasive species (Weldon et al. 2004) and an emerging infectious disease (Daszak et al. 1999; Rosenblum et al. 2010), and hence its distribution is not at equilibrium. Niche modeling has predicted the potential of *Bd* to invade southern and central Africa, parts of south-east Asia, southern and central North America, Europe, and South America (Ron 2005). Within Australia the impact of the fungus is expected to be highest in the eastern and southeastern mountainous regions along the eastern seaboard (Rödder et al. 2008), however it is expected to reach its physiological limits approximately 300–400 km from the coastline (Rödder et al. 2008).

Although numerous studies within Australia have detected *Bd* along the eastern coastline (Kriger et al. 2007a; see Ron 2005 appendix) there have been no studies aimed at detecting *Bd* west of the mountain range known as the Great Dividing Range in southeastern Queensland. Considering the impacts that *Bd* has had on amphibian populations worldwide it is essential to determine the presence of this fungus in untested areas. The aim of our study was to sample for *Bd* in the unsampled western plains of southeastern Queensland, Australia.

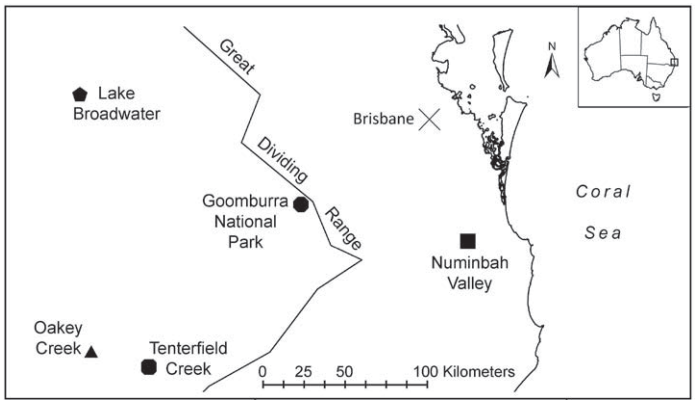

FIG. 1. Location of sites sampled for *Batrachochytrium dendrobatidis* east and west of the Great Dividing Range (approximate location represented by the left line), Queensland, Australia. The coastline (right line) and Queensland's capital city, Brisbane (X) are shown.

We sampled for *Bd* in early September 2007 at four sites west of the Great Dividing Range (GDR) in southeast Queensland, including a previously known site of *Bd* on the GDR in Goomburra National Park (Ron 2005) (Fig. 1). We also sampled a well-studied site in Numinbah Valley (east of the GDR) as a reference site to address annual variation in prevalence (Kriger and Hero 2006; Kriger et al. 2007a) (Fig. 1). Sampling was carried out in spring (26 September 2007 to 10 October 2007) to maximize the probability of detecting *Bd* (Kriger and Hero 2007). We swabbed 212 adult frogs, with 145 sampled west of the Great Dividing Range and 67 sampled at Numinbah Valley (Table 1).

A standardized swabbing method was used (Kriger et al. 2007a), modified slightly as we did not swab the dorsal surface. Swabs were stored on ice and kept in a refrigerator until analysis (Van Sluys et al. 2008). Frogs were individually handled with clean 250 mm x 200 mm plastic bags, which were discarded after use to avoid the transfer of *Bd* and to minimize the chances of sample contamination. All frogs were swabbed by the same individual (JMH) to avoid swabber bias. To circumvent sampling the same frog twice, individuals were not released until all frogs had been swabbed at each site.

Quantitative polymerase chain reaction techniques (qPCR), as described by Boyle et al. (2004) with modifications described by Kriger et al. (2006), were used to determine *Bd* presence. A positive infection was considered any frog which produced a result of one or more zoospores in the triplicate PCR analysis procedure (Kriger et al. 2007b). Prevalence for each species per site was calculated.

The site with the highest prevalence (25.4%) was Numinbah Valley, located east of the GDR. This was followed by Goomburra National Park (12.5%), located just west of the GDR, Lake Broadwater (7.1%), and Tenterfield Creek (2.2%; Table 1). We detected *Bd* at only one site sampled at Lake Broadwater. This site consisted of 19 of the 28 individuals surveyed for the Lake Broadwater Conservation Park. All frogs detected with *Bd* were from water bodies that are either permanent or temporary riverine systems (Table 1).

Our study has extended the known range of *Bd* west of the GDR, in southeast Queensland, Australia, by approximately

TABLE 1. Sites where frogs were sampled for *Batrachochytrium dendrobatidis* (*Bd*), both west and east of the Great Dividing Range (GDR) in southeast Queensland, Australia. *Bd* prevalence per site and per frog species sampled is shown. Habitat types of sampling locations were either permanent or ephemeral water bodies (streams or ponds).

85 km (Ron 2005). This range extension falls within the area predicted by the Rödder et al. (2008) model.

All *Bd*-positive samples were taken from frogs captured in riverine systems that have flowing water for at least some time of the year. The absence of detection of *Bd* from ponds/dams at Lake Broadwater may be due to low sample size (Table 1). However Kriger and Hero (2007) found low prevalence of *Bd* in anuran pond/dam breeders when compared with stream breeders. The low prevalence and lack of *Bd* within the other permanent river systems sampled in this study (Tenterfield and Oakey Creek) suggest the distribution of *Bd* in the drier inland parts of Australia may be patchy or absent.

Our results suggest that prevalence is lower at sites west of the GDR when compared with sites east or on the GDR, thus suggesting that prevalence decreases within populations of frogs with increasing distance west of the GDR in south-eastern Queensland. Prevalence was low west of the GDR when compared with our samples both east of (Nerang River, Numinbah) and on the GDR itself (Darlymple Creek, Goomburra). This is not surprising because *Bd* has been readily detected in areas with high rainfall and cooler temperatures (Kriger and Hero 2006; Kriger and Hero 2008, Kriger et al. 2007a), and the rainfall gradient decreases and average temperatures increase with increasing distance west of the GDR (Hijmans et al. 2005).

The Houston Toad (*Bufo* [= *Anaxyrus*] *houstonensis*) is endemic to south-central Texas, USA, currently occupying suitable habitat in seven counties (Forstner and Dixon 2010). Population sizes are in steady decline, and the populations in Bastrop County are considered the most robust and sustainable of the remaining populations (Seal 1994), with current estimates of less than 500 adult individuals (M.R.J. Forstner, unpubl.). The Houston Toad was listed as endangered in 1970, and has been referred to as "probably the rarest and most endangered amphibian in the United States" (USFWS 1978). The factors linked to global amphibian decline (e.g., habitat alteration, global environmental change, environmental contaminants, introduced species, emerging infectious diseases) or combinations thereof are likely primary threats to the Houston Toad as well (Seal 1994; Peterson et al 2004). Yet, published information on infectious diseases of this endangered taxon is still lacking.

Chytridiomycosis is a recently emerged infectious disease caused by the fungus *Batrachochytrium dendrobatidis* (*Bd*). It has been implicated as a significant contributor to amphibian population declines worldwide (Berger et al. 1998; Garner et al. 2005; Ouellet et al. 2005). The presence of *Bd* has been confirmed in many states of the USA (Davidson et al. 2003; Ouellet et al. 2005; Rothermel et al. 2008) including south-central Texas near Bastrop County where it was detected in several endemic salamander species (*Eurycea nana*, *E. neotenes*, *E. pterophila*, *E. sosorum*, and *E. tonkawae*) and in Blanchard's Cricket Frogs (*Acris crepitans blanchardi*) (Gaertner et al. 2009a; Gaertner et al. 2009b).

The aim of this study was to expand the previous research on *Bd* in south-central Texas in order to assess the potential threat that the presence of *Bd* might pose to Houston Toads. These studies took advantage of existing DNA from toes of *B. houstonensis* and a sympatric toad, *Bufo* [*Anaxyrus*] *nebulifer* (Coastal Plain Toad) originally sampled for a long-term conservation study on *B. houstonensis* in Bastrop County and available from the M.R.J. Forstner Frozen Tissue Catalogue held at Texas State University-

San Marcos. Toads were sampled opportunistically and via drift fences around small ephemeral and semi-permanent reservoirs on the Griffith League Ranch (30.215390°N, 97.255320°W), Bastrop State Park (30.110745°N, 97.292980°W), and several other sites within federal designated Houston toad Critical Habitat in Bastrop County, Texas.

Toes were collected between 2001 and 2007 from January to May, a period prior to the average monthly temperature rising above 25°C. All samples were stored in 95% ethanol at –80°C: 105 *B. houstonensis* (2001, N = 8; 2002, N = 24; 2003, N = 16; 2004, N = 2; 2005, N = 7; 2006, N = 24; 2007, N = 24) and of 96 *B. nebulifer* (2001, N = 21; 2002, N = 3; 2003, N = 6; 2004, N = 18; 2006, N = 24; 2007, N = 24) (Table 1). DNA was isolated using a Wizard® SV 96 Genomic DNA Purification System (Promega) on a Biomek® 3000 Laboratory Automation Workstation (Beckman Coulter), a DNeasy™ Tissue Kit (QIAGEN Inc.), or a standard phenol-chloroform method (Sambrook et al. 1989). We tested for *Bd* using a nested PCR approach (Gaertner et al. 2009a). The nested PCR used primers ITS1f and ITS4 targeting conserved regions of the 28S and 18S rRNA to amplify the 5.8S rRNA gene and the flanking internal transcribed spacer (ITS) of all fungi (White et al. 1990). Purified PCR products were then used as a template for the second PCR reaction using the primer set Bd1a and Bd2a which is specific for *Bd* (Annis et al. 2004). Reactions were then examined for the presence of a 300-bp fragment (Annis et al. 2004) using gel electrophoresis (2% agarose in TAE buffer) (Sambrook et al. 1989).

Overall, 29 of 201 (14.4%) toads tested were positive for the 300-bp fragment, indicating *Bd* presence, including 6 of 105 *B. houstonensis* and 23 of 96 *B. nebulifer* (Table 1). More than 80% (24 of 29) of *Bd*-positive samples were obtained in year 2006. Samples obtained in 2003 (23 tested) and 2005 (7 tested) were all *Bd*-negative, whereas years 2001 (2/29 or 6.9%), 2002 (1/28 or 3.6%), 2004 (1/20 or 5.0%), 2006 (24/48 or 50%) and 2007 (1/48 or 2.1%) had positive samples though mostly at low percentages (Table 1). All amplicons of the appropriate size were purified, and then sequenced at the DNA Sequencing Facility of the Institute for Cellular and Molecular Biology at the University of Texas at Austin, TX. Sequences were compared to GenBank/EMBL databases and aligned using BLAST (Pearson and Lipman 1988) and alignment functions in Geneious 4.8.3 (Drummond et al. 2009). Sequence diversity was limited. Two haplotypes were discovered that shared more than 99% similarity to sequences in the databases representing *Bd*. Haplotype A (GenBank Accession HM153084) was detected in toads sampled in 2001, 2002, 2004 and 2006 and in both *B. houstonensis* and *B. nebulifer*. Haplotype B (HM153085) was not detected in samples collected prior to 2006 and was detected only in *B. nebulifer* (Table 1). These results demonstrate the presence of *Bd* in populations of *B. houstonensis* and *B. nebulifer* as early as 2001 and within federally designated Critical Habitat of the Houston Toad. Any further statements about the significance of this observation and consequences for current and future conservation efforts for *B. houstonensis* specifically remain speculative, and require additional studies.

Detection of *Bd* in zero or only a few individuals during most years may depend on seasonal and environmental conditions as is the case in other wild amphibians (Gaertner et al. 2009b; Kriger and Hero 2006; Voordouw et al. 2010). Although this situation does not correspond with the commonly viewed perception of disease dynamics, populations of frogs with low numbers of infected individuals have been reported (Voordouw et al. 2010). Populations of *Xenopus* frogs in South Africa, for example, have carried the fungus with a relatively low prevalence (about 2.7%) for as long as 65 years (Weldon et al. 2004). Alternatively, these results could underestimate the presence of *Bd* due to sampling bias as a consequence of low numbers or of preferential predation on infected toads in nature. Assuming a low prevalence of infection, approximately 60 individuals would need to be tested to provide a 95% certainty of detecting *Bd* on at least one animal (Skerratt et al. 2008).

Of particular interest are the results from year 2006. Despite populations from all other years lacking detections or with relatively low numbers of positive samples, 50% of the samples collected in 2006 (N = 48) were *Bd*-positive. Differences in the prevalence of *Bd* in anuran populations have been seen frequently but were attributed to seasonal differences in temperature (Kriger and Hero 2007; McDonald et al. 2005; Ouellet et al. 2005; Retallick et al. 2004) or precipitation (Gaertner et al. 2009b; Ron 2005). Weather data retrieved for 2001–2007 breeding seasons (January to June) from the National Climatic Data Center using the average for three sites surrounding Bastrop (Smithville, Station ID 20024578; Cedar Creek, Station ID 20024579 and Elgin, Station ID 20024696) reveal that 2006 was notably hotter and dryer for the period, with an increase in temperature by 1.5°C and a decrease in precipitation by 256 mm from the average for the period. The conditions were the inverse necessary for optimal growth of *Bd* (Berger et al. 2004; Lamirande and Nichols 2002), even though a significant negative relationship between the occurrence of *Bd* and precipitation has been reported (Kriger and Hero 2007). That relationship, however, was suggested to be affected more by low temperature conditions than by the concomitant dry conditions. The increase in occurrence of *Bd* during 2006 in our study might therefore not be a consequence of the environmental conditions in this year alone, but may be significantly affected by the environmental conditions in the preceding drought in 2005 with 204 mm below average precipitation. Environmentally stressed toads could be more susceptible to *Bd* which may consequently result in an increase in occurrence of *Bd* the following year. A similar scenario was discussed in one of our previous studies that suggested high occurrence of *Bd* on salamanders at specific sites was caused by environmental stress from pollution originating from urban runoff (Gaertner et al. 2009a). Relief from the drought with precipitation 91 mm above average during year 2007 and thus reduction in environmental stress could then have resulted in a reduction in occurrence of *Bd*. The fluctuation in occurrence of *Bd* on toads, however, could also be a function of sample size and sampling strategy that were originally designed to retrieve information on the genetic diversity of toads. Low sample numbers, but also the inability to conduct repetitive sampling of sites with high numbers of infected toads in consecutive years might therefore have influenced the detection of *Bd* through time.

Data obtained for 2006 showed not only much higher occurrence of *Bd* on toads, but also species-specific differences in occurrence, with a much higher detection in *B. nebulifer* (83%, 20 of 24 toads) than in *B. houstonensis* (17%, 4 of 24 toads). Differences in occurrence of *Bd* in sympatric amphibian species

TABLE 1. Prevalence of *Batrachochytrium dendrobatidis* in *Bufo houstonensis* and *Bufo nebulifer* at localities in Bastrop County, Texas, USA, from January to May 2001 to 2007.

[1]Sites with the prefix BAN (Bastrop Co. 'north,' see Forstner and Dixon [2010]) are located 8–11 km W and WSW of the TX21/US290 junction. Site BAPp (Bastrop County 'p12') is about 10 km WSW of TX21/US290 junction. Sites with the prefix BAS (Bastrop Co. 'south') are within a 9 km radius E of TX21/TX95 junction, mostly between TX21 and TX71, with few sites W of TX21. All locations are within federally designated Critical Habitat for the species.

have been observed (Goka et al. 2009; Peterson et al. 2007; Retallick et al. 2004), with few studies linking the occurrence of *Bd* to the disease (Retallick et al. 2004). The increase in occurrence of *Bd* in 2006 was coincident with the identification of a new haplotype (haplotype B) that differed from the previously identified one (haplotype A) by a 10 bp insertion after base number 64. Haplotype B was identical to the most prominent *Bd* haplotype found in *Eurycea* salamanders from central Texas (GenBank Accession numbers EU779859, EU779862, EU779864, and EU779867) (Gaertner et al. 2009a) suggesting strain-specific differences affect occurrence and potential virulence as demonstrated in other studies (Berger et al. 2005; Goka et al. 2009; Retallick and Miera 2007). Because haplotype B was not found in *B. houstonensis*, but only in *B. nebulifer* so far, differences in host specificity might be present. This may also be evidence of *B. nebulifer* acting as a vector for *Bd* similar to assumptions for the American Bullfrog (*Lithobates catesbeianus* [*Rana catesbeiana*]; Daszak et al. 2004; Hanselmann et al. 2004) as *B. nebulifer* dispersed into Houston Toad habitats during the spring of 2006 as the drought left no breeding ponds in the grassland patches.

In any case, these speculations need additional studies with more samples and a sampling strategy directed towards repeated and seasonal analyses of *Bd* at a site with high occurrence of *Bd*. These studies should include comparative analyses of water and sediment samples for presence and abundance of *Bd* and the respective haplotypes as a function of environmental characteristics during the season.

Acknowledgments.—The authors are indebted to the National Science Foundation (GK–12 grant No. 0742306) and Texas State University–Department of Biology for financial support. The research was carried out in compliance to the rules overseen by the Texas State Institutional Animal Care and Use Committee (IACUC, permit 0721–0530–7), the state of Texas (SPR–0102–191) and the USFWS (TE039544–0).

Batrachochytrium dendrobatidis fungus (*Bd*) has recently been implicated as a cause of massive amphibian declines and extinctions globally (Berger et al. 1998; Daszak et al. 1999; Bosch et al. 2001). *Bd* surveillance typically relies on direct sampling of amphibians using non-invasive molecular techniques to screen for the presence of *Bd* DNA on their skin. Histological exams are also used to microscopically examine amphibian skin, identify zoospores, and diagnose the extent of *Bd* infection (clinically known as chytridiomycosis). However, histological examination is invasive and may not show *Bd* infection if zoospores are not actively being shed by an infected animal (Annis et al. 2004). *Bd* is a water-borne pathogen, so it is also important to test environmental water samples for this fungus, but this has proven difficult using microscopy (Annis et al. 2004). However, several recent studies have used molecular methods to successfully screen for the presence of *Bd* DNA in water and soil samples (Lips et al. 2006; Kirshtein et al. 2007; Walker et al. 2007).

Molecular detection of *Bd* DNA typically involves traditional polymerase chain reaction (PCR) with *Bd*-specific primers followed by visualization using agarose gel electrophoresis (Beard and O'Neill 2005; Lips et al. 2006). Although this technique has been successfully used to detect the presence of *Bd* DNA, it may be ineffective at detecting *Bd* DNA if the DNA concentration is low (early stage of infection and/or diluted environmental samples) since low concentration of template DNA may lead to PCR failure. To address this lack of sensitivity, some researchers have turned to real time fluorescently-based PCR (RT-PCR) for detection of *Bd* DNA (Boyle et al. 2004; Knapp and Morgan 2006). RT-PCR has been shown in some studies to be significantly more sensitive to dilute concentrations of DNA than conventional PCR (Helps et al. 2001; Balamurugan et al. 2009), however this is not always the case (Bastien et al. 2008).

There are currently few data available regarding the distribution of *Bd* in amphibians in the state of New Jersey, USA, making the threat of this pathogen to local amphibians unknown. A recent study of the Pinelands of southern New Jersey did not detect *Bd* in animals or environmental samples (Di Leo 2010). In this study we tested 43 samples (27 animals and 16 water) from the New Jersey School of Conservation in Northern New Jersey for the presence of *Bd* DNA using a traditional PCR-based approach and species-specific primers designed by Annis et al. (2004). We then re-screened these samples using the same primers in an RT-PCR assay to compare the two methods and screen for the presence of *Bd* in New Jersey.

Sampling was carried out at the 97-ha (240-acre) New Jersey School of Conservation (NJSOC, Branchville, Sussex County, New Jersey, 41.22690°N, 74.74975°W), the environmental field campus of Montclair State University, which is surrounded by undeveloped land including Stokes State Forest, High Point State Park, the Delaware Water Gap National Recreation Area, and other properties held by nonprofit conservation organizations. The property is primarily mixed deciduous forest with streams, vernal pools, and a small (6 ha) artificial lake, Lake Wapalanne. The NJSOC is located within the Flat Brook watershed of the Delaware River basin, an area with relatively high water quality (Delaware River Basin Commission 2008). However, the region is heavily used for recreation (e.g., trout fishing and hiking), raising the possibility that disease could be introduced through movement of fishing gear or introduction of live amphibians used as bait, as reported elsewhere (Picco and Collins 2008). This potential connection, however, is speculative since there are currently no empirical data available. We sampled water and animals at Lake Wapalanne and several vernal pools located within 1 km of the lake, and opportunistically sampled animals elsewhere on NJSOC property.

Sampling was conducted between 26 June and 18 August 2009. Animals were caught by net or hand and swabbed with a sterile cotton swab over all body surfaces with additional attention paid to the ventral surface. Swabs were stored in sterile 1.5 ml Eppendorf tubes for 2 to 6 h until transported to the laboratory where they were frozen at -20°C. Tadpoles were put in a 1.5 ml Eppendorf tube with approximately 500 µl water that was collected from the tadpole's environment. The tadpoles were allowed to "swim" in the tube of water for 30 sec to 1 min. Tadpoles were removed from the tube and returned to the environment. Samples were stored at room temperature for 2 to 6 h until transported to the laboratory where they were frozen at -20°C. We collected samples from the following species and life stages: *Lithobates clamitans* (8 tadpoles, 3 juveniles, and 9 adults), *L. palustris* (2 adults), *L. sylvatica* (1 adult), *Notophthalmus viridescens* (2 adults), and *Ambystoma maculatum* (2 larvae) for a total of 27 animals. We considered these animals to belong to the same geographic site given the close proximity of their habitat, so we did not sterilize nets during sampling.

Environmental samples consisted of water from the same aquatic habitats where animals were caught. Approximately 500 µl water were collected from each of 11 ephemeral ponds and one small stream, and four locations from Lake Wapalanne (16 samples total). Water samples were stored separately in sterile 1.5 ml Eppendorf tubes as described above.

We added 200 µl deionized water to the tubes with swabs and vortexed the tubes for approximately 30 sec. No additional water was added to the water or tadpole samples. We thawed water and tadpole samples, then vortexed them for approximately 30 sec. All samples were boiled in a boiling water bath for 10 minutes to lyse open zoospores if present.

A sample of *Bd* preserved in ethanol provided by J. Longcore (University of Maine) was used to isolate positive control DNA. We centrifuged 100 µl of the culture at 13,000 RPM for one min, and resuspended it in 500 µl of deionized water twice to remove ethanol and dilute cells. The positive control was then boiled for

10 min to lyse open zoospores.

Traditional PCR.—Bd-specific primers (Bd1a and Bd2a) designed by Annis et al. (2004) were used to amplify an approximately 300-bp fragment of the 5.8S rRNA gene. Ten microliters of each test sample and 2 µ1 of positive control DNA were used in 25-µ1 PCR reactions that included the following components: 0.4 µM forward and reverse primers, 1.5 mM $MgCl_2$, 0.2 mM dNTPs, and 0.1 U/µl taq polymerase. PCR reactions were subjected to one cycle of 95°C for 5 min followed by 30 cycles of 95°C for 30 sec, 60°C for 30 sec, and 72°C for 30 sec, followed by a final 7-min extension at 72°C. All reactions were run in a GeneAmp 9700 Thermalcycler (Applied Biosystems). Appropriate negative controls using water in place of DNA were included with each PCR run. PCR products were checked for the presence of the *Bd*-specific 5.8S fragment on 2% 1XTAE gels followed by SYBR Safe (Invitrogen) staining and UV illumination.

RT- PCR.—We used 11.5 µl of each test sample in 25-µl PCR reactions that included the following components: 0.4 µM Bd1a and Bd2a primers (Annis et al. 2004) and 12.5 µl of Brilliant II SYBR Green qPCR Master Mix (Agilent Technologies). We used 11.5 µl of test sample to maximize the amount of *Bd* DNA used in the reaction if it was present in the test sample. We ran positive control reactions using 0.5 ng/µl *Bd* DNA and negative control reactions using water in place of DNA under the same conditions. PCR reactions were subjected to 1 cycle of 95°C for 10 min followed by 40 cycles of 95°C for 45 sec, 60°C for 30 sec, and 72°C for 30 sec. All RT-PCR reactions were run on a Stratagene Model Mx 3000 P Thermalcycler (Stratagene Technologies). We rescreened all positive samples in triplicate using RT-PCR to verify the results.

All animals used in this study were alive at the point of capture and none appeared to show obvious symptoms of chytridiomycosis. None of the 43 samples tested positive for *Bd* DNA using traditional PCR (Table 1). When these samples were retested using RT-PCR however, three tested positive for *Bd* DNA: two *L. clamitans* juveniles from separate sites and one water sample from Lake Wapalanne (Table 1). Results were repeatable for all three trials of the RT-PCR. Indeed, both of the *L. clamitans* juveniles that tested positive produced a fluorescence intensity that was comparable to the positive control (Table 2). All positive and negative controls yielded expected results for both traditional and RT-PCR.

To our knowledge, this is the first published account of the presence of *Bd* in New Jersey amphibians or environmental samples. It is not surprising that *Bd* is present in New Jersey given that it has been documented in New York and Connecticut (Longcore et al. 2007). If we had only used the traditional PCR-based method we would have erroneously determined that *Bd* might not be present at the New Jersey School of Conservation (although sample sizes were low), potentially missing an important opportunity to study the distribution and effects of this pathogen in native amphibians. Given that *Bd* was detected in two animals and one water source, all from different locations within the NJSOC, it is possible this pathogen is widespread at NJSOC. We are currently focusing our efforts on increasing sample sizes for all species and life stages present at the NJSOC to quantify infection loads and determine species-specific effects of infection.

Because we had negative results from all of the tadpole samples we cannot be sure that our protocol is sensitive enough to detect *Bd* in this life stage. Future studies will focus on substantially increasing tadpole sample size and verifying the efficacy of this screening method by comparing it with an established method of detection in tadpoles. Additionally, given the small sample size (<60) of all species and life stages it will be necessary to increase sample sizes to more accurately assess the prevalence of *Bd* at NJSOC (Skerratt et al. 2008).

We were able to detect the presence of *Bd* DNA without the use of a traditional DNA extraction protocol, even in an environmental sample. Simply boiling skin swab and water samples to lyse zoospores without the use of a costly and time-consuming DNA extraction method was sufficient. This was especially surprising given that environmental water samples may contain PCR-inhibitors. For a rapid presence/absence screen, this method is a viable

TABLE 1. Results of traditional and RT-PCR for the presence (+/-) of *Batrachochytrium dendrobatidis* DNA from animals (A) and environmental samples (B) collected from the New Jersey School of Conservation, Branchville, Sussex County, New Jersey, USA.

Positive *Bd* DNA Control (1 ng DNA)	19.9	7304.3
L. clamitans juvenile 1	22.4	8160.6
L. clamitans juvenile 2	24.5	7844.1
Positive Water Sample	32.1	4572
Negative Control	>40	202.7

alternative to current methods, making it potentially important for rapid assessment or in situations where funds are very limited.

Perhaps more important however, are the results of our PCR technique comparison, which could have a potential impact on future molecular screening procedures throughout the *Bd* research community. In this study, we detected *Bd* in 3 of 43 samples using RT-PCR, but none using traditional PCR. Our results strongly support the need to use the more sensitive RT-PCR screening method when using a non-invasive PCR-based detection technique for *Bd* DNA.

Acknowledgments.—We thank Paola Dolcemascolo and Jan Sodos for assistance with field sampling. Animals were sampled under New Jersey Department of Environmental Protection Division of Fish and Wildlife Scientific Collecting Permit #29033. The study was approved by the Montclair State University Animal Care and Use Committee and adhered to SSAR guidelines for use of amphibians in field research. Support was provided by a New Jersey Conserve Wildlife Matching Funds Grant.

Batrachochytrium dendrobatidis (*Bd*) has been found with varying prevalence on amphibians in the northeast, midwest, and southeast United States (Longcore et al. 2007; Zellmer et al. 2008; Green and Dodd 2007; Rothermel 2008), but surveys in Pennsylvania have failed to find infected individuals (Glenney et al. 2010). We studied between-pond variation in *Bd* infection levels in amphibians of northwestern Pennsylvania, USA. In doing so, we focused our sampling efforts on three species, Green Frogs (*Rana clamitans*), Red-spotted Newts (*Notophthalmus viridescens*) and Wood Frogs (*Rana sylvatica*). These species are locally abundant and, if commonly infected, could serve as an indicator species for assessing *Bd* presence in ponds.

Our surveys were designed to maximize the number of ponds sampled for *Bd* occurrence. We swabbed up to 12 individuals per species for *Bd* at 10 ponds containing Green Frog tadpoles, 8 ponds containing Red-spotted Newts and 2 ponds containing Wood Frog adults between 1 April and 28 May 2008 (Table 1). This sampling scheme has low statistical power to detect true negative results within a pond (e.g., Skerratt et al. 2008), but it is sufficient for *Bd* detection at ponds with moderate to high infection prevalence. For sampling efficiency, we visited each pond only once and limited the life stages that we sampled to larval Green Frogs, adult Red-spotted Newts and adult Wood Frogs. While adult frogs are more commonly sampled, we focused on larval

Green Frogs because they often overwinter as tadpoles, which increases the opportunity for infection to occur, and because high sample sizes can be obtained. In addition to the three focal species, we also opportunistically sampled adult Northern Two-lined Salamanders (*Eurycea bilineata*), Northern Dusky Salamanders (*Desmognathus fuscus*), and adult Spring Peepers (*Psuedacris crucifer*) for *Bd*. All Red-spotted Newts and Green Frogs were collected in permanent ponds, whereas Wood Frogs and Spring Peepers were sampled in ephemeral ponds. Salamanders were sampled in an ephemeral stream. Sites were surveyed until 10 individuals of a species were collected or no more animals could be found in a reasonable time frame.

To sample *Bd*, animals were swabbed thirty times along keratinized tissues where *Bd* zoospores are highly concentrated (Marantelli et al. 2004). Tadpoles were swabbed (Medical Wire Company MW113) across mouthparts, adult frogs were swabbed along the drink patch, inside lower thighs and foot webbing, and newts were swabbed on the ventral side, back legs, and feet. Swabs were stored in 95% ethanol and DNA was extracted and analyzed for *Bd* presence and quantity using quantitative PCR

(Boyle et al. 2004). This method is highly sensitive and can detect very low-level infections that might be missed with other methods (Hyatt et al. 2007). Samples were run in triplicate and were re-run from the same extraction in cases where results yielded only one or two positive results. A re-run sample was considered positive if at least 3 of 6 wells tested were positive. Such variability between wells is common in samples with low infection levels (personal observation). Quantitative estimates of infection levels were made by averaging positive results within a sample.

To minimize cross-contaminating animals, gloves and equipment that contacted frogs were sterilized with 70% ethanol and dried between handling of individuals and all other equipment was sterilized with a 10% bleach solution or discarded after leaving a pond (Johnson et al. 2003).

Our results suggest that *Bd* is widespread throughout northwestern Pennsylvania, USA, yet infection prevalence and intensity varies among species (Table 1). Red-spotted Newts had the highest prevalence of the three species that could be surveyed with sufficient sample sizes. We did not find infected newts in 2 of the 9 ponds, however, the sample size was not sufficient to confidently demonstrate that these ponds were infection-free. Among tested individuals, infection loads (measured in terms of zoospore equivalents) varied over three orders of magnitude among sites. There are few other data examining *Bd* infection loads in Red-spotted Newts, but infection has been reported for museum specimens in eastern North America and more recently in field-collected Red-spotted Newts from the southeastern USA (Ouellet et al. 2005; Rothermel et al. 2008). This suggests that *Bd* infection in Red-spotted Newts is not uncommon. Interestingly, the closest area to our study site that has been surveyed for *Bd* (Delaware Water Gap National Recreation Area) did not find infections in Red-spotted Newts or any other tested species (e.g., *Rana sylvatica*, *Pseudacris crucifer, Hyla versicolor*; Glenney et al. 2010). Many of the newts collected in our study also exhibited cysts indicating infection by the mesomycetozoan *Amphibiocystidium viridescens* (pers. obs.), and newts in the surrounding area have been shown to carry infections of other parasites, including trematodes, nematodes, trypanosomes, acanthocephelans, helminths and bacteria (Raffel et al. 2009). This raises the question as to whether co-infection with other pathogens alters *Bd* infection rates in Red-Spotted Newts.

Bd infection also was found in Green Frog tadpoles (Table 1). Although infection prevalence was lower than that found in Red-spotted Newts, infection was detected in more than 50% of ponds and sample sizes were not large enough to confidently detect low-level infections in the other ponds. On average, infection loads of Green Frog tadpoles were lower than that found in newts. This may reflect the fact that tadpoles possess less keratinized tissue than newts (Marantelli et al. 2004). Other surveys examining *Bd* infection in Green Frog adults and metamorphs with qPCR and histology have found higher infection levels (18–36% in Maine from 2000–2002; Longcore et al. 2007), which also may reflect less keratinized tissue in tadpoles (Marantelli et al. 2004). It is likely that *Bd* has been prevalent in Green Frogs for some time; the earliest evidence for *Bd* in North America came from a museum specimen collected in 1961 in Quebec (Ouellet et al. 2005). The tadpoles sampled in our study were in their second larval year, allowing ample time for animals to be infected. Since newts co-occur in ponds with Green Frogs, *Bd* may have been transmitted across species.

No individuals of the four other species sampled were *Bd*-positive: Northern Two-lined Salamanders (N = 2, ravine by Shenango Oxbow); Northern Dusky Salamanders (N = 4, ravine by Shenango Oxbow); Spring Peepers (N = 2, Trailer Park Pond); and Wood Frogs (Table 1). However, our sample sizes were small and sample sizes >59 are recommended to detect *Bd* when prevalence is low (Skerratt et al. 2008). Past studies of Wood Frogs in New England and Michigan, USA show low to moderate prevalence of *Bd* (>1 % to 16.7% with qPCR and histology; Longcore et al. 2007; Zellmer et al. 2008), but previous studies of Wood Frogs in eastern Pennsylvania (N = 28) did not find infected individuals, despite using sensitive testing techniques (i.e., qPCR, Glenney et al. 2010). *Bd* also has been found in the Northern Two-Lined Salamander and the Dusky Salamander, suggesting that these species are susceptible to infection (Byrne et al. 2008; Grant et al. 2008). We failed to find any records of infected Spring Peepers, although they have been previously surveyed for *Bd* infections (Byrne et al. 2008; Longcore et al. 2007; Ouellet et al. 2005; Rothermel et al. 2008; Glenney et al. 2010).

Overall, our results correspond with other studies showing that *Bd* is present in areas where amphibian population declines have not been documented (Green and Dodd 2007; Longcore et al. 2007; Rothermel 2008; Zellmer et al. 2008). Though we only sampled at a single point in time, high prevalence of infection and relatively low infection intensities in both Green Frogs and Red-spotted Newts suggest that *Bd* is not uncommon in northwest Pennsylvania and both species might be good indicators for *Bd* presence in this region. Although no pathology was observed in infected individuals we suggest that further monitoring is necessary to test whether this observation is consistent.

Acknowledgments.—Steve Bagnull, Jenise Brown, Rickey Cothran, John Hammond, Forest Raub, Tim Schwartz, and Aaron Stoler helped in the collection of amphibians. Thanks to Aaron Stoler, Will Brogan, Rickey Cothran, Jessica Hua, and Heather Schaffery for providing comments on this manuscript. Funding was provided by a McKinley Grant and NSF graduate research fellowship to MLG. All work was approved by IACUC and collections were permitted by the Pennsylvania Fish and Boat Commission.

SSAR Poster Awards for 2011

This is the inaugural year for the SSAR Poster Award. The SSAR Poster Awards will provide recognition for the best student posters presented at the annual meeting of the SSAR. To be eligible, the presented poster must be the result of research conducted by the individual making the presentation. The research must have been conducted while the student was enrolled in either an undergraduate or graduate degree program. Students entering the competition must be members of SSAR. The presentations will be judged by the SSAR student prize committee. One SSAR Poster Award of U.S. $100 (plus a book gift from the University of California Press) may be given in each of the following four categories:

- Evolution, Genetics, & Systematics
- Ecology, Natural History, Distribution, & Behavior
- Physiology & Morphology
- Conservation & Management

The SSAR Poster Award will be judged by the following criteria:

- Quality of Research
- Quality of the Visual Display of the Research
- Professionalism and Confidence of the Presenter

For specific recommendations on preparation of posters, please consult the SSAR website:
http://ssarherps.org/pdf/PosterRecommendations.pdf

† Deceased 12 June 2009

Gaige's Rain Frog, *Pristimantis gaigeae* (Strabomantidae) is a direct-developing anuran species ranging from the Atlantic lowlands in extreme southeastern Costa Rica through eastern Panama and on the Pacific versant in central Colombia (Savage 2002). The species is considered a mimic of dendrobatid species, exhibiting a pair of red, orange, or golden dorsolateral stripes on a black body, similar to the two toxic species *Phyllobates aurotaenia* and *P. lugubris* (family Dendrobatidae) with which some populations of *Pristimantis gaigeae* are sympatric (Fig. 1).

It is the intent of the authors to present methods that have been utilized to successfully maintain and reproduce *Pristimantis gaigeae* in captivity. As little information is currently available on the captive husbandry and reproduction in species of *Pristimantis*, we believe the information provided herein may prove useful in future attempts to maintain *ex situ* populations of this and other species of the genus.

SPECIMEN ACQUISITION AND HUSBANDRY METHODS

The group of *P. gaigeae* at the Atlanta Botanical Garden (ABG) consisted of one male and two females collected in 2005 from the vicinity of El Valle de Antón and one male collected from the vicinity of El Copé, both in Provincia de Coclé, Panamá. The specimens were collected and exported as a part of the Amphibian

Recovery and Conservation Coalition (ARCC) project. This was a collaborative effort between ABG and Zoo Atlanta aimed at learning the logistics of an ex situ response to the rapid spread of chytridiomycosis through amphibian populations in Panama (Lips et al. 2006; Gagliardo et al. 2008).

After importation, specimens were put through a quarantine period of thirty days during which all were prophylactically treated for *Batrachochytrium dendrobatidis* infection following the protocol suggested by Dr. Brad Lock (Zoo Atlanta) and Dr. Brad Wilson (The Veterinary Clinic West, Marietta, Georgia). Post-quarantine and treatment, the three specimens from El Valle were housed in an enclosure measuring 60 x 30 x 90 cm with live plants (*Philodendron* and *Calathea*), substrate consisting of moistened sphagnum moss, and pieces of cork bark for cover. The single male from El Copé was housed in an enclosure measuring 25 x 30 x 50 cm and furnished as for the El Valle group. Light was provided by one 55-watt power compact fluorescent fixture over each enclosure and temperatures were maintained between 18–28°C. A 12-hour on and 12-hour off light cycle was maintained throughout the year. Humidity and moisture were maintained through use of an automated misting system. The diet of the adults consisted almost exclusively of domestic crickets (*Acheta domestica*) that were gut loaded with a varied fresh vegetable diet and dusted at alternate feedings with Rep Cal D3® and finely powdered Men's Health® vitamins. Occasionally, nymphs of the Turkistan Roach (*Blatta lateralis*) and Lobster Roach (*Nauphoeta cinerea*) were offered.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Adult male *Pristimantis gaigeae* collected from El Valle De Anton, Provincia De Coclé, Panama. Photo by Robert Hill.

In May 2006, the three El Valle specimens were transferred to the private collection of Paul Crump in Houston, Texas, USA. The specimens were housed together in an enclosure measuring 60 x 30 x 90 cm. Furnishings consisted of moistened sphagnum moss substrate, live plants, and pieces of cork bark as refugia. Misting occurred four times daily, with the longest misting event taking place for five minutes each day at 00:00 then gradually decreasing to one minute by 12:00 and increasing gradually back to five minutes. Temperatures were maintained from 21–24°C. Light was provided by two 1.2 m fluorescent full spectrum bulbs on a 12-hour on and 12-hour off cycle. Specimens were fed a diet of domestic crickets and fruit flies (*Drosophila hydei*) that were dusted at each feeding with Miner-All I®.

In April 2008, the three adult El Valle specimens and one captive offspring were returned to ABG. Upon return, specimens were put through quarantine procedures as described above. They were then transferred to a temporary enclosure measuring 50 x 25 x 30 cm that was furnished with a moistened sphagnum moss substrate, live plants, and plastic refugia. This enclosure was misted once daily by use of a spray bottle.

In 2008, a modified shipping container was acquired by ABG and outfitted for use as a holding and breeding facility for amphibians (Fenolio et al. 2009). This included the group of four adult *P. gaigeae*. The El Valle group was split, with the male and one female kept together, and the additional female placed with the El Copé male. Each pair of frogs was housed in a Zoo Med® terrarium measuring 30 x 30 x 45 centimeters. Each was furnished with lighting, live plants, substrate, and refugia as above. Humidity and moisture were regulated through the use of an automated misting system operating six times daily during a simulated wet season from November–April and two times daily during a simulated dry season from May–October. Individual misting events ranged from three to 10 minutes each with the shortest misting events taking place during the simulated dry season.

Breeding

Axillary amplexus has been observed in *P. gaigeae*, though further observations are necessary to determine duration before oviposition and fertilization. No calls have been noted or recorded and, according to Savage (2002), this species does not have an advertisement call. Egg attendance behavior has been observed in both sexes and occurs in other members of the Strabomantidae (Ryan 2005).

Multiple breeding events have occurred at ABG; the first being in May 2006 with 36 eggs deposited on a piece of cork bark. The male was observed in attendance of the egg clutch. Viability was low and none of the resultant offspring survived. Several breeding events were observed in 2009 with clutch sizes ranging from 22–37 eggs. Eggs measured approximately 5 mm in diameter and typically were buried in the substrate under one of the plastic cover objects or within the root systems of the plants; typically, one or more eggs did not get covered with the rest of the clutch and in more than one instance, were observed up to several centimeters from the main egg mass. These scattered, isolated eggs typically failed to hatch. However, eggs were deposited on top of a plastic cover object on more than one occasion by each female. Both sexes have been observed attending clutches, however never together or at the same time. In instances where egg clutches have been observed in the open and uncovered, viability appeared to be lower in comparison to the typically covered clutches. However, even under these exposed circumstances, an adult was observed in attendance. The time period between clutches during peak breeding activity was from six to eight weeks.

Handling of Eggs and Hatchlings

Eggs were carefully removed from the adult enclosure and incubated on a 5–10 cm layer of moistened sphagnum moss in plastic quart-size deli cups until hatching, which occurred from 28–39 days post-oviposition (Fig. 2). The incubation cups are maintained at 21–26°C with all eggs completely covered with moss so that they were not exposed to light. Interestingly, in a recent manipulation, a portion of an egg mass was left completely exposed to light and development continued normally and unimpeded (R. Hill, pers. obs.). Newly hatched *P. gaigeae* measured approximately 5 mm in length. Because of this small size, and the propensity of injury during movement, eggs were separated and placed two each into rearing containers late in development. Rearing containers consisted of quart-size plastic deli cups containing a layer of moistened sphagnum moss and a vented lid. To prevent desiccation of the tiny young, roughly 50% of the lid was covered with plastic wrap to maintain high humidity.

Hatchlings proved difficult to rear successfully and often began showing what appeared to be signs of calcium deficiency within the first several weeks. The diet at this stage consisted nearly exclusively of springtails (*Collembola* sp.). Anecdotal observation suggests that the use of liquid and powdered vitamin supplementation added to the diet of the springtails may potentially increase hatchling survivorship (J. Kaylock, pers. obs.). Desiccation proved to be a major concern. Some specimens were observed to dry out on the sides of their enclosures. The covering of at least 50% of the vented lid of the rearing container combined with daily misting mitigated this issue. Another method utilized was to maintain the hatchlings as stated above, but without the plastic wrap and placed inside a larger enclosure with automated misting. In this arrangement, we found that the mist soaks and penetrates the vented lid to provide additional moisture and ambient humidity. Both rearing methods have proven successful thus far. Once the young frogs moved onto larger food items such as flightless fruit flies (*Drosophila melanogaster* and *D. hydei*) and newly hatched domestic crickets, growth was rapid.

Conclusions

Pristimantis gaigeae is listed as a species of Least Concern by the World Conservation Union (IUCN Red List, 2009). Of the 426 currently recognized species of *Pristimantis* considered by the IUCN Red List, 67 are listed as Endangered, Critically Endangered, or Vulnerable with 38 listed as Data Deficient. Very few species of *Pristimantis* are currently held in managed collections and even fewer have been routinely reproduced. While *P. gaigeae* may not be a species of particular conservation concern at this point in time, the methods and techniques used in the successful husbandry and reproduction of this species may prove useful for other members of the genus for which *ex situ* management programs may eventually be deemed necessary.

Acknowledgments.—This manuscript is dedicated in gratitude and to the memory of Julia Beth Kaylock (1980–2009), whose dedication to and passion for amphibian conservation and husbandry helped bring about the current successes with *P. gaigeae* and other Panamanian amphibians. Special thanks to the personnel and government of the Republic of Panama. Permits were granted by the Autoridad National del Ambiente (permit SEX/A-81-05). Acknowledgments also to Joseph R. Mendelson, III and Jennifer Cruse-Sanders for assistance during the editorial process and to Brad Wilson for providing images. Further gratitude goes to George Rabb, Cynthia Jeness, and Bill and Claire Simmons for their support of *ex situ* conservation efforts for Panamanian amphibians.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations in the field, with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance.

Electronic submission of manuscripts is requested (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Figures can be submitted electronically as JPG files, although higher resolution TIFF or PDF files will be requested for publication. Please DO NOT send graphic files as imbedded figures within a text file. Additional information concerning preparation and submission of graphics files is available on the SSAR web site at: http://www.ssarherps.org/HRinfo.html. Manuscripts should be sent to the appropriate section editor: **Jackson D. Shedd** (crocodilians, lizards, and *Sphenodon*; jackson.shedd@gmail.com); **Charles W. Painter** (amphibians; charles.painter@state.nm.us); **John D. Willson** (snakes; hr.snake.nhn@gmail.com); and **James Harding** (turtles; hardingj@msu.edu).

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*. SSAR Herpetol. Circ. 37:1–84, available from SSAR Publications Secretary, ssar@herplit.com; for Mexico as it appears in Liner and Casas-Andreu 2008, *Standard Spanish, English and Scientific Names of the Amphibians and Reptiles of Mexico.* Herpetol. Circ. 38:1–162), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Some further comments. The role of the "Standard Names" lists (noted above) is to standardize English names and comment on the current scientific names. Scientific names are hypotheses (or at least represent them) and as such their usage should not be dictated by a list, society, or journal.

Recommended citation for notes appearing in this section is: Medina, P., and R. L. Joglar. 2008. *Eleutherodactylus richmondi*: reproduction. Herpetol. Rev. 39:460.

CAUDATA — SALAMANDERS

PLETHODON CINEREUS (Eastern Red-backed Salamander). **WETLAND HABITAT.** *Plethodon cinereus* are noted for their ability to live and breed in terrestrial "forest litter habitats in deciduous, northern conifer, and mixed deciduous-conifer forests" (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.). However, although "many individuals are found far from any visible water supply and the species is less dependent on water than many others, [*P. cinereus* can be found] in greatest numbers in fairly damp situations" (Bishop 1941. The Salamanders of New York. New York State Mus. Bull. 324). Scattered reports in the literature confirm the species' use of moist habitats, for example, two dead *P. cinereus* were observed in leaves of the bog-dwelling Purple Pitcher Plant (*Sarracenia purpurea*; Hughes et al. 1999. Herpetol. Rev. 30:160). We observed *P. cinereus* in moss along shorelines of wetlands and also observed the species under rocks and leaf litter in stream channels in Maine. We are aware of no previous literature documenting the occurrence and breeding of *P. cinereus* in wetland shoreline. Two publications document *P. cinereus* presence in stream channel habitat: 25 *P. cinereus* were detected under rocks (18–30 cm in diameter, 30% embedded in substrate) in ≥ 6 streams in Maine (Perkins and Hunter 2006. J Wildl. Manag. 70[3]:657–670) and the species was observed beneath stones in small streams in Maryland (Cooper 1956. Herpetologica 1956:165–166). Our observations further describe the stream channel habitat used by *P. cinereus*. The occurrence of *P. cinereus* in wetland and stream habitat has relevance to managers and biologists surveying for the species.

We thoroughly searched the vegetation growing in wetlands and on the shoreline of palustrine wetlands (N = 67) in Maine, USA (Acadia National Park, Massabessic Experimental Forest, U.S. Fish and Wildlife Service Sunkhaze Meadows National Wildlife Refuge, University of Maine Foundation Penobscot Experimental Forest, University of Maine Demeritt Forest) during 2001–2003. We searched by parting vegetation growing <30 cm from water with methods described by Chalmers and Loftin (2006. J. Herpetol. 40:479–486). We detected 49 *P. cinereus* (of which at least 12 were gravid) and one clutch of eggs in vegetation in wetlands (N = 26; 39% of wetlands surveyed). We typically observed the *P. cinereus* located directly above water and in *Sphagnum* or *Thuidium* (feather moss). Twice we observed *P. cinereus* with Four-toed Salamanders (*Hemidactylium scutatum*). We observed an adult of each species entwined at one wetland. We found eggs of *P. cinereus* and *H. scutatum* within <8 cm of each other at another wetland. The *P. cinereus* clutch was located in *Sphagnum* along the shoreline of a slow moving stream in a palustrine wetland with a Red Maple (A*cer rubrum*) canopy, alder (*Alnus incana*) understory, and herbaceous layer of Blue-joint Reed Grass (*Calamagrostis canadensis*). The *P. cinereus* clutch (detected 20 June 2002 by J. Bertman) was on the underside of a rotten, leaning stump surrounded by *Sphagnum*. The clutch was attended by a female and contained six eggs. We observed the *P. cinereus* on 1 July attending two eggs attached to the stump and two eggs attached to *Sphagnum*. Twice, we observed *P. cinereus* in a wetland >10 m from the wetland edge on islets (<2 m^2) that the salamanders may have reached during low water. The species can swim (Bishop 1941, *op. cit.*); however we observed *P. cinereus* placed in water initially sink, then surface and swim to shore.

We surveyed stream salamanders in Acadia National Park, Mount Desert Island, Maine, 15 May–21 June 1999 and in August 2001–2003. The only stream salamander species currently vouchered on the island is the Northern Two-lined Salamander (*Eurycea bislineata bislineata*; Brotherton et al. 2004. Acadia National Park Amphibian and Reptile Inventory: March–September 2001. Tech. Rep. NPS/NER/NRTR-2005/007. National Park Service, Woodstock, Vermont). We detected *P. cinereus* with two survey methods: 25-m long transects parallel to the stream with width 1 m onto shore and 1 m into water, and "belt" transects per-

pendicular to the stream for length spanning the stream bed plus 1 m onto each shore and 1 m width. We made 72 observations of juvenile and adult *P. cinereus* (≥ 26 individuals) in transects at four (Breakneck Stream, Duck Brook, Hadlock Brook, Kebo Stream) of six streams surveyed. *Plethodon cinereus* were observed in stream bars and bank face. Microhabitat used by individuals on stream bars typically was under rock cover and on a moist substrate of sand, gravel, or cobble. Salamanders occupying the stream bank face typically were under wet leaf litter and on soil or bedrock substrate. Salamanders were occasionally found on substrate with pooled water. *Plethodon cinereus* were observed in stream channel habitat during both periods of flow and periods of low water in which intermittent flow was interspersed with pools in the stream channel.

Plethodon cinereus are found in Maine along the vegetated shoreline of wetlands and the channels and banks of streams as well as in habitat farther from water. Individuals could be moving into wet habitat temporarily during dry conditions (e.g., summer drought) when the forest floor is otherwise too dry for the species. Alternately, *P. cinereus* may use wet habitats for a longer duration if the conditions of the surrounding terrestrial habitat (shallow, rocky, well-drained soil) are typically too dry for the species. Large numbers of Eastern Red-backed Salamanders migrate towards wetlands with *Hemidactylium scutatum* and Blue-spotted Salamanders (*Ambystoma laterale*) in the spring in Vermont (J. Andrews, unpubl. data). The timing of these migrations is too early for seasonal drying of the forest floor, which typically occurs in late summer, and Andrews suggests that at these wetlands, the salamanders may leave the wetlands only for overwintering (J. Andrews, pers. comm.) Streams in our study area annually decrease in surface water area in the summer and subsequently expose cover rocks in the stream channel. We observed *E. bislineata* moved to those cover rocks closest to the remaining surface water. *Plethodon cinereus* may have an increased opportunity to use stream bed habitat during summer drought because of a greater number of cover objects available and a simultaneous decrease in interspecific competition for cover. *Plethodon cinereus* typically are displaced from moist habitats by other plethodontid species via competitive interactions (Hairston 1949. Ecol. Monogr. 19:47–73) and depredation (Hairston 1980. Am. Nat. 115:354–366). The relatively few amphibian species (*Eurycea bislineata bislineata*, *Desmognathus fuscus fuscus*, *Gyrinophilus porphyriticus*, in streams, and *Hemidactylium scutatum* along wetland shoreline) occupying these habitats in Maine may improve the opportunity for *P. cinereus* to colonize these habitats with less interspecific competition than present in more southerly regions.

Further study is necessary to determine the spatial extent, duration, and seasonal patterns of stream- and wetland-habitat use by *P. cinereus* in Maine. *Plethodon cinereus* also may use wetland habitats elsewhere in its range, although this had not been reported in published literature. Researchers and surveyors of *P. cinereus* should consider the possibility that this species may occur in wetland habitats in northern portions of the species' range.

These data were obtained during research funded by the United States Geological Survey (USGS) Maine Cooperative Fish and Wildlife Research Unit, University of Maine, and USGS Amphibian Research and Monitoring Initiative. We thank field assistants J. Bertman and A. Murphy. The manuscript was improved by the thoughtful comments of J. Andrews and M. B. Kolozsvary.

PLETHODON PETRAEUS (Pigeon Mountain Salamander). **PREDATION.** *Plethodon petraeus* is a large (to 84 mm SVL) scansorial plethodontid salamander endemic to karst areas of a single mountain slope in Walker and Chatooga counties in northwest Georgia, USA (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. 587 pp.; Wynn et al. 1988. Herpetologica 44:135–143). Due in part to its restricted range and recent discovery, no predators have been reported for *P. petraeus* (Jensen and Camp 2005. *In* M. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 833–834. Univ. California Press, Berkeley). We report the first account of predation on *P. petraeus*, though by what is likely an insignificant and opportunistic predator.

At 1430 h on 17 April 2010, one of us (GJB) found a live juvenile *P. petraeus* suspended in a spider web >30 cm deep in a narrow rock crevice on the Lost Wall, on Pigeon Mountain, Walker Co., Georgia, USA (34.6592°N, 85.3717°W, WGS 84). The spider was not present at the web, so the species could not be determined, but based on the shape and location of the web we tentatively identify the family as Agelenidae (North American funnel-web spiders). Other examples of spider predation on salamanders include a wolf spider (*Hogna helluo*) feeding on a Blue-spotted Salamander (*Ambystoma laterale*; McLister and Lamond 1991. Can. Field-Nat. 105:574) and experimental data from a challenge of phyletic bias in predator-prey interactions in which adult wolf spiders (*Gladicosa pulchra*) were offered and preyed upon juvenile Spotted Salamanders (*Ambystoma maculatum*; Rubbo et al. 2003. J. Zool. Lond. 261:1–5). Both species of wolf spiders (Lycosidae) are generalist cursorial ambush predators and do not use webs to trap their prey, so this report repre-

FIG. 1. Juvenile *Plethodon petraeus* tangled in an agelenid spiderweb. Walker Co., Georgia, USA.

sents the first example of entrapment of a salamander in a spider web.

We thank J. Perry of the North Carolina State Museum of Natural Sciences for assistance with identification of the spider web.

PSEUDOEURYCEA GIGANTEA (Giant Salamander). **MAXIMUM SIZE.** *Pseudoeurycea gigantea* is one of Mexico's largest plethodontids, reaching 161 mm SVL (Parra-Olea et al. 2005. Herpetologica 61:145–158). On 20 Nov 2009, we collected an adult male *Pseudoeurycea gigantea* in cloud forest, 0.7 km S and 0.2 km W of San Juan de las Flores, municipality of San Bartolo Tutotepec, Hidalgo, Mexico that exceeds the total length of earlier records (161 mm SVL, 228 mm TL; Parra-Olea et al. 2005, *op. cit.*). The specimen measured 149 mm SVL and 314 mm TL which represents the largest total size of this species reported. The specimen is deposited in the Colección Herpetológica, Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo (CIB-UAEH 2549). *Pseudoeurycea gigantea* is an endemic salamander restricted to a small area of eastern Mexico, found in the states of Puebla, Hidalgo, and Veracruz (Parra-Olea et al. 2005, *op. cit.*).

Fieldwork was funded by CONACyT- 95828.

***SIREN* SP.** (Mudpuppy). **PREDATION.** Although wading birds are likely predators of *Siren* (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.), records of specific sirenid predation events are scarce. On 15 January 2010, at approximately 1636 h a Great Egret (*Ardea alba*) was observed eating a *Siren* in the Audubon Swamp Garden in Magnolia Plantation and Gardens, Charleston County, South Carolina, USA. The egret took at least three minutes after being seen with the siren in its beak to consume it. The siren was approximately the length of the bill of the Great Egret and could have been either a Greater Siren (*S. lacertina*) or Lesser Siren (*S. intermedia*). Although previous records are available for "large, eel-like salamanders" being robbed from Great Egrets and White Ibis (*Eudocimus albus*) by American Crows (*Corvus brachyrhynchos*), these records could be for Two-toed Amphiuma (*Amphiuma means)* or *S. lacertina* (Kilham 1984. Colonial Waterbirds 7:143–145). This observation provides additional evidence of wading birds as predators of sirenids and further narrows confirmed predation by Great Egrets to members of the *Siren* genus.

Submitted by **THOMAS M. LUHRING**, Savannah River Ecology Laboratory, Aiken, South Carolina 29808, USA. Current address: University of Missouri, Division of Biological Sciences, 105 Tucker Hall, Columbia, Missouri 65211, USA; e-mail: tmlhwb@mizzou.edu.

SIREN INTERMEDIA (Lesser Siren). **EXTRALIMITAL INTRODUCTION/REPRODUCTION.** The natural range of *Siren intermedia* is confined to the Atlantic and Gulf Coastal Plain from Virginia to Mexico, and extends north in the Mississippi Valley to Illinois, Indiana, and southwestern Michigan (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts).

On 25 March 2005 at least one *S. intermedia* individual was released into a permanent man-made backyard pond (500 gal, 90 cm deep) in San Mateo Co., California via an aquatic plant shipment from Arkansas. The pond had previously been stocked with Fathead Minnows (*Pimephales promelas)*, which were likely the main source of prey, and various aquatic plants which provided sufficient cover. On 10 April 2008, I discovered larval *S. intermedia* in the pond. I proceeded to drain the pond and collected approximately 40 larvae and two large putative adult individuals. Multiple adult Bullfrogs (*Rana catesbeiana)* were also recovered. All sirens were transferred to the Department of Evolution and Ecology, University of California, Davis, California and maintained in aquaria (HBS188896–906).

Although constrained mostly to the eastern United States, this event demonstrates that *S. intermedia* have the potential to reproduce in a California coastal climate even in the presence of aquatic predators such as the Bullfrog. Furthermore, breeding populations could potentially result from individuals released into permanent hydroperiod aquatic habitats in California. The transition of California's aquatic resources from vernal pools to large stock ponds has previously facilitated the establishment of the non-native Tiger Salamander (Fitzpatrick and Shaffer 2004. Evolution 58:1282–1293).

ANURA — FROGS

BUFO BOULENGERI (African Green Toad). **CANNIBALISM.** *Bufo boulengeri* (Stöck et al. 2006 Mol. Phylogenet. Evol. 41:663–689; Stöck et al. 2008 BMC Evol. Biol. 8:56) is a prolonged breeder which typically inhabits temporary and shallow water bodies (Bologna and Giacoma 2006. *In* Sindaco et al. [eds.], Atlante degli Anfibi e dei Rettili d'Italia, pp. 306–311. Ed. Polistampa). In arid areas, similar to those used for reproduction in southern Morocco, *B. boulengeri* seems to be unevenly distributed, with dense populations in oases widely separated by unsuitable dry areas. Due to the coexistence of different developmental stages in the same wetland, levels of intraspecific competition are high.

A wetland situated near Tiznit, Morocco (28.123164°N, 11.296131°W, 87 m. elev.) was examined on 4 April 2010. The

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Female *Bufo boulengueri* exhibiting cannibalism behavior.

wetland was located in a stony plain. The plant community, within the inframediterranean belt, was a scrubland dominated by *Euphorbia echinus*, *Lycium intrincatum*, *Launaea arborescens*, *Frankenia* spp., *Witthania frutescens*, *Fagonia cretica*, and *Lavandula multifida*. A high density of several dozen individual *B. boulengeri* metamorphs were observed per m^2. Adults were found along the banks of the wetland and the cannibalistic behavior of an adult female was observed (Fig. 1). The total length of the adult was 84 mm and the total length of the recently metamorphosed *B. boulengeri* was 31 mm.

Both in natural or experimental conditions, many anurans frequently exhibit cannibalistic behavior, and these interactions are thought to be relatively common, at least in larval stage (Alford 1999. *In* McDiarmid and Altig [eds], Tadpoles: The Biology of Anuran Larvae, pp. 240–278. Univ. Chicago Press, Chicago, Illinois; Crump 1992. *In* Elgar and Crespi [eds.], Cannibalism: Ecology and Evolution Among Diverse Taxa, pp. 256–276. Oxford Univ. Press, London, UK). Our observation is the first record of cannibalism for this species and contributes to our knowledge of the ecology of *B. boulengeri*.

Submitted by **ENRIQUE GARCÍA-MUÑOZ**, Departamento de Biología Animal, Biología Vegetal y Ecología, Universidad de Jaén, Campus de las Lagunillas s/n, 23071 Jaén, Spain (e-mail: engamu@gmail.com); **LUIS PEDRAJAS**, Centro de Rescate de Anfibios y Reptiles, c/ Real 48, 23680 Alcalá la Real, Spain; **JESÚS BASTIDA**, Departamento de Biología Animal, Biología Vegetal y Ecología, Universidad de Jaén, Campus de las Lagunillas s/n, 23071 Jaén, Spain; and **FRANCISCO CEACERO**, Departamento de Ciencia y Tecnología Agroforestal y Genética, Universidad de Castilla-La Mancha, Campus Universitario s/n, 02071 Albacete, Spain.

CERATOPHRYS CRANWELLI (Cranwell's Horned Frog). **DIET**. *Ceratophrys cranwelli* is a large terrestrial frog endemic to the Gran Chaco ecoregion of South America. Anurans have been noted as comprising a large proportion of this species' diet, but the only anuran diet items confirmed have been *Physalaemus biligonigerus* and an unidentified *Leptodactylus* sp. (Scott and Aquino 2005. *In* Donnelly et al. [eds.], Ecology and Evolution in the Tropics: A Herpetological Perspective, pp. 243–259). Here I confirm an anuran in the diet of *C. cranwelli*.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. *Ceratophrys cranwelli* metamorph consuming a *Leptodactylus bufonius* metamorph.

On 15 March 2009 at 2100 h I discovered a metamorph *C. cranwelli* preying upon a small anuran around a temporary pond in the Isoceño community of Yapiroa, Province Cordilleria, Department Santa Cruz, Bolivia (19.6000°S, 62.5667°W; WGS 84). I identified the anuran as a *Leptodactylus bufonius* (Fig. 1). Though the *L. bufonius* was still alive (indicated by its multiple attempts to push itself out of the *C. cranwelli*'s mouth), the *C. cranwelli* proceeded to force the *L. bufonius* into its mouth using its hands. After ca. 20 min, the *L. bufonius* had been completely consumed by the *C. cranwelli*. To my knowledge, this is the first report confirming *L. bufonius* in the diet of *C. cranwelli*.

Funding for this trip was provided by the Applied Biodiversity Science National Science Foundation Integrated Graduate Education and Research Traineeship doctoral program (NSF-IGERT Award #0654377) at Texas A&M University.

CORYTHOMANTIS GREENINGI (Casque-headed Tree Frog). **EGG PREDATION**. *Corythomantis greeningi* has a wide distribution in the Caatinga of northeastern Brazil where it occupies temporary water bodies in this semiarid region. The species generally reproduces in lotic environments in stony river beds (Juncá et al. 2008. Zootaxa 1686:48–56). On 29 March 2009 at 900 h we observed eggs of *C. greeningi* being predated by tadpoles of *Proceratophrys cristiceps* (about 30 individuals in Gosner stages 40–42), in a small puddle formed in a streambed, situated in Olho d'água, municipality of Santa Cruz da Baixa Verde, State of Pernambuco, Brazil (8.58889ºS, 38.176944ºW; WGS 84; 852 m elev). Such predation of eggs has been reported in other studies (Rodrigues and Filho 2004. Herpetol. Rev. 35:373–373; St. Peter et al. 2008. Mus. Biol. Mello Leitão 24:111–118). This is the first record of oophagy reported for *P. cristiceps*. Specimens of tad-

poles and images of the predation were deposited in the Herpetological Collection of Universidade Federal Rural de Pernambuco / Unidade Acadêmica de Serra Talhada - UFRPE / UAST (Lot 31), Recife, Pernambuco, Brazil.

We thank Mr. A. Timóteo for authorization to collect the data, Pibic for a scholarship, and IBAMA for the license #11218-1.

DENDROPHRYNISCUS CARVALHOI (Carvalho's Tree Toad). **DEFENSIVE BEHAVIOR**. Thanatosis is a defensive behavior by which an animal feigns death to escape predation. As many predators pursue only live prey, this behavior may be very effective.

The genus *Dendrophryniscus* is native to South America occurring in the Atlantic Rainforests of Brazil, Amazonian Colombia, Ecuador, Peru, and Brazil, and at Guianas (Frost 2009. Amphibian Species of the World: an Online Reference. Version 5.3 accessed 12 Feb. 2009. Electronic database accessible at http://research.amnh.org /herpetology/amphibia/. American Museum of Natural History, New York). *Dendrophryniscus carvalhoi* is known from the type locality in Santa Tereza municipality and ca. 130 km SW at the Parque Nacional do Caparaó, both in Espírito Santo state, Brazil (Cassimiro et al. 2008. Herpetol. Rev. 39:362). Herein we describe thanatosis in *D. carvalhoi*.

During a herpetological survey between 27 Oct and 3 Nov 2006, in Parque Nacional do Caparaó, Fazenda Pico da Bandeira, Santa Marta municipality, Minas Gerais State (20.467222°S, 41.733889°W; WGS 84; elev. ca. 1135 m), we observed defensive behavior of *D. carvalhoi*. One individual displayed thanatosis with stiff-leg behavior in response to hand capture. This species defends itself by stiffening its legs in the same way as was recently described for *D. brevipollicatus* and *D. leucomystax* (Bertoluci et al. 2007. Alytes 25:61–67). The frog assumes the stiff-legged posture when touched and remains immobile for almost one minute. Other specimens collected when disturbed for the first time in the field assumed this same behavior, and also sometimes under laboratory conditions.

Thanathosis with stiff-leg behavior maybe more common than previously thought and widespread among frogs living in forest litter. The behavior may be underestimated considering that certain species only exhibit thanathosis under specific conditions, with predator-specific responses (Gibbons and Gibbons 2009. Herpetol. Rev. 40:440). Moreover, the congruence among thanathosis behaviors among different species of *Dendrophryniscus* (Bertoluci et al. 2007, *op. cit.;* Russell 2002. Herpetol. Rev. 33:302) may reflect a closer relationship among *D. leucomystax*, *D. brevipollicatus*, and *D. carvalhoi* relative to *D. minutus*, in which thanathosis involves flipping over and presenting the ventral surface (Bertoluci et al. 2007, *op. cit.;* Russell, *op. cit.*).

We thank Lilian Duarte de Matos, and our field guide Paraíba, for field assistance. The Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA) provided support and collecting permits (numbers 185/2005, and 238/2006). Estevão José Marchesini Fonseca, Director of the Parque Nacional do Caparaó, provided lodging facilities and support.

EUPHLYCTIS CYANOPHLYCTIS (Indian Skipper Frog). **ALBINISM.** During field collections, we observed two albino tadpoles of *Euphlyctis cyanophlyctis*, one at an early stage of development (Gosner Stage 28; 31 mm in length; Gosner 1960. Herpetologica 16:183–190) and the other near metamorphosis (Gosner Stage 43; 61.8 mm in length) in a pond on the University of Pune Campus (18.554925°N, 73.86335°E), Maharashtra, India. These tadpoles were present with large numbers of conspecifics having normal pigmentation and were very conspicuous. The tadpoles were unique in that they had golden yellow color throughout and had no black pigmentation (Fig. 1A) compared to the normal tadpoles (Fig. 1B). In the early stage tadpole, although black pigmentation was absent throughout the body, the oral appara-

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Albino tadpoles of *Euphlyctis cyanophlyctis* along with normal tadpoles at different stages of larval development.

tus with jaw sheaths and tooth rows were black (Fig. 1C). From the ventral side, blood vessels, gills, and the heart were visible through the transparent skin due to a lack of pigmentation. The eyes were pink and very prominent, especially during darkness when one of the tadpoles was caught. The pond is permanent, although mostly dry during the summer months. The albino tadpole at metamorphic climax (Fig. 1D) was conspicuous in the group of normal tadpoles (Fig. 1E) when collected. This tadpole metamorphosed in the laboratory within 3–4 days and the frog was normal except for pigmentation (Fig. 1F; 24.2 mm body length, 1.3 g mass). We observed behavioral aspects of its feeding and habitat sharing with normal tadpoles and observed no differences. One of the froglets matured around 4 months after metamorphosis in the laboratory and was found to be a male. We do not know the factors responsible for this phenomenon in nature. Although we have observed tadpoles from this pond for four years this is our first observation of albino tadpoles of *E. cyanophlyctis*.

Submitted by **NARAHARI P. GRAMAPUROHIT** and **SAMADHAN K. PHUGE**, Department of Zoology, University of Pune Ganeshkhind, Pune 411 007, India (e-mail: naraharipg@unipune.ernet.in).

EXERODONTA SUMICHRASTI (Sumichrast's Treefrog). **SEMITERRESTRIAL LARVAE.** Except for species where the male or female frog transports the tadpoles (e.g., dorsally, marsupial pouch, etc.), free-living anuran tadpoles typically are aquatic during the entire larval period. The tadpoles of a very few species are known to be semiterrestrial, moving about on tree branches and/or rocks near water (Lawson 1993. Herpetol. Nat. Hist. 1:27–90; Wells 2007. The Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago, Illinois, 1148 pp.). Of the genera listed by Wells (2007, *op. cit.*), this behavior has been noted in but three genera in the Neotropics, the South American taxa *Leptodactylus rugosus*, *Cycloramphus*, and *Thoropa*. On 27 June 2000 I observed many tadpoles later identified as *Exerodonta sumichrasti* in a stream crossing Hwy 196, 14.2 rd km N Atoyac, Guerrero, Mexico, 610 m elev. (17.32445°N, 100.2474167°W). Most of the tadpoles were resting on rocks in splash pools below small waterfalls, while some were observed in the actual course of the stream. A small number of tadpoles (ca. 10) were observed moving across wet surfaces of rocks in the splash zone, ca. 1 m above the water line, and continuing to move vertically away from the water line. There were some lichens on the rock surfaces where the tadpoles were located, but no evident algae or moss. The tadpoles appeared to be using their enlarged mouthparts as the primary locomotor organ; larvae of this species are not gastromyzophorous. A small number of tadpoles were collected (vouchers deposited at Facultad de Ciencias, Universidad Autónoma de México: MZFC-JRM 4563), and photographic images of the semiterrestrial behavior were deposited at University of Texas at Arlington (UTA slide no. 38677–78). I believe this is the first report of semiterrestrial larvae in any Mesoamerican anuran.

I thank K. Lips and D. Mulcahy for assistance in the field. This work was funded by the National Geographic Society. Field work was conducted of the authority of Permiso Oficio No. DOO. 02.-2545.

FEJERVERYA LIMNOCHARIS (Paddy Field Frog). **DIET.** *Fejerverya limnocharis* is widely distributed throughout the Indian subcontinent and feeds mainly on small insects (Chanda 2002. Handbook of Indian Amphibians. ZSI., Kolkata, India; Daniel 2002. The Book of Indian Reptiles and Amphibians. BNHS and Oxford Univ. Press, Mumbai, India; Dutta 1992. Amphibians of India and Sri Lanka [Checklist and Bibliography]. Odyssey Pub. House, Orissa, India), but there is little information on the ecology of the species.

During herpetological surveys on 16 July 2009 at 2322 h, we heard the distinct advertisement calls of anurans. Based on spectrum-homologies of our anuran sound bank as well as on morphological features we identified *Fejerverya limnocharis* in the chorus. During call recordings we observed a *F. limnocharis* feeding on a large earthworm. The frog was holding the earthworm in its jaws and pushing it into its mouth with the help of its forelegs, repeating this motion follow short intervals. Other anurans of larger size such as *Hoplobatrachus tigerinus* readily feed on earthworms (Danials 2004. Amphibians of Peninsular India. Indian Academy of Science and University Press, Hyderabad, India), although there is no report of such feeding behavior for *F. limnocharis.* The *F. limnocharis* under observation was only 3 cm SVL, while it was feeding on an earthworm measuring ca. 10 cm. Reports of *F. limnocharis* feeding on small insects are available, although this is the first report on such an unusual feeding behavior of this anuran.

HYLA WRIGHTORUM (Arizona Treefrog). **PREDATION**. *Hyla wrightorum* is discontinuously distributed from Arizona and New Mexico, south into northern México. The population of *H. wrightorum* in and near Arizona's Huachuca Mountains, Canelo Hills, and adjacent northern Sonora are isolated from the nearest populations along the Mogollon Rim to the north in Arizona and the Sierra Madre Occidental in Sonora, México (Gergus et al. 2004. Copeia 2004:758–769; Maldonado Leal et al. 2009. Herpetol. Rev. 40:108). Recently, the U.S. Fish and Wildlife Service (USFWS) assigned the Huachuca/Canelo population of *H. wrightorum* the status of Candidate for listing as Threatened or Endangered under the U.S. Endangered Species Act as a Distinct Population Segment (DPS; USFWS 2007. Fed. Register 72:234). Among the threats to the DPS identified by USFWS was the potential for predation by introduced species, particularly American Bullfrogs (*Lithobates catesbeianus*), but empirical data were lacking (USFWS, *op. cit*.). We report the first documented instance of predation by *L. catesbeianus* on *H. wrightorum*.

On 14 July 2008, from 1245–1520 h MST, in Scotia Canyon, Huachuca Mountains, Cochise Co., Arizona, USA (31.4572°N, 110.3976°W, NAD 83, ca. 1890 m elev.), we were engaged in a larger effort to remove American Bullfrogs from aquatic habitats throughout the canyon, including a permanent, spring-fed pond near the head of the canyon where American Bullfrogs had bred for the past several years. Thunderstorms were moving through the area, and male *H. wrightorum* were calling sporadically from a well-known breeding site; a small, temporary pond ca. 50 m from the permanent pond. At that time we collected an adult male *L. catesbeianus* (SVL = 140 mm) that was calling from the temporary pond, and discovered remains of four adult *H. wrightorum* in its stomach; three were males (SVL = 30, 31, 32 mm), one was too decomposed to be measured or sexed. We returned to the site on 17 July 2008, and at 1540 h collected a female *L. catesbeianus* (SVL = 120 mm; with developing ova) at the same site. Her stomach contained three adult *H. wrightorum*, one male (SL = 34 mm); two could not be measured or sexed. Weather was overcast and a single *H. wrightorum* called at 1602 h.

Although the indiscriminate predatory habits of *L. catesbeianus* are well known and widely published (Casper and Hendricks. 2005. *In* M. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 540–546. Univ. California Press, Berkeley), it is clear from our data that a few adult *L. catesbeianus* can have a profound impact on small, isolated populations of rare species such as *H. wrightorum* in the Huachuca Mountains where breeding sites might comprise only 2–30 adults (Gergus et al. 2005. *In* M. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 461–463. Univ. California Press, Berkeley). In addition, since each of the *H. wrightorum* for which sex could be identified were adult males, it raises the possibility that the *L. catesbeianus* might have used acoustical cues to target their prey (Casper and Hendricks 2005, *op. cit.*), although it might simply be the case that females had not yet moved to the breeding site.

American Bullfrogs are known to be capable of moving quickly over relatively large distances during Arizona's summer monsoon (pers. obs.; Suhre et al. 2006. Unpubl. abstract. Joint Meeting of Ichthyologists and Herpetologists, New Orleans, Louisiana; C. Schwalbe and P. Rosen, pers. comm.). Thus, it is not unreasonable to predict that *L. catesbeianus* could temporarily occupy other nearby *H. wrightorum* breeding sites in the Huachuca Mountains and seriously deplete those populations as well, and could do so without that impact being quickly or readily identifiable.

Our fieldwork adhered to guidelines outlined in Beaupre et al. (2004. Guidelines for Use of Live Amphibians and Reptiles in Field and Laboratory Research, 2nd ed. Herpetological Animal Care and Use Committee, American Society of Ichthyologists and Herpetologists).

Submitted by **THOMAS R. JONES** and **ROSS J. TIMMONS**, Nongame Branch, Arizona Game and Fish Department, 5000 W. Carefree Highway, Phoenix, Arizona, 85086, USA (e-mail: tjones@azgfd.gov, rtimmons@azgfd.gov).

HYLODES cf. AMNICOLA (NCN). **PREDATION.** Kingfishers are preferentially fish predators, although they may also include arthropods, crabs, amphibians, and reptiles in their diet (Sick 1997. Ornitologia Brasileira. Editora Nova Fronteira, Rio de Janeiro. 912 pp.). At ca. 1000 h on 17 Oct 2008, during a field trip to "Mata da Prefeitura" (22.2180556°S, 45.2569444°W; 1150 m elev.), in the municipality of Cristina, Minas Gerais State, southeastern Brazil, we observed an adult Ringed Kingfisher, *Megaceryle torquata*, preying on an adult torrent-frog, *Hylodes cf. amnicola*. After capture, the frog was beaten repeatedly on the bird's perch; after the frog was consumed the bird flew away. This is the first report of predation of this species.

We thank Itamar A. Martins for valuable suggestions and Cristina's City Hall for AFBJ support.

HYPSIBOAS SEMILINEATUS (NCN). **ALBINISM**. *Hypsiboas semilineatus* is a treefrog widely distributed in the Atlantic Forest of Brazil (Haddad et al. 2008. São Paulo: Editora Neotropica). Tadpoles of this species are found in lentic bodies of water forming large schools (D'Heursel and Haddad 2002. Iheringia 92:99–104). On 20 October 2007 at 1900 h and on 19 July 2008 at 1400 h we collected albino tadpoles of *H. semilineatus* at two localities in the Atlantic Forest in northeast Brazil: Reserva Particular Frei Caneca, municipality of Jaqueira (8.721667ºS, 35.850833ºW) and Reserva Particular da Usina São José, municipality of Igarassu (35.000556ºS, 7.817778ºW). These were 39.3 mm SVL/Gosner Stage 33 and 52.1 mm SVL/Gosner Stage 37, respectively. Albinism in anuran larvae is rare in nature (Rodrigues and Filho 2004. Herpetol. Rev. 35:373–373). This is the first record of albino tadpoles for this species.

The tadpoles were deposited in the herpetological collection of the Universidade Federal Rural de Pernambuco/Unidade Acadêmica de Serra Talhada - UFRPE/UAST (lot 30 and 31), Serra Talhada, Pernambuco, Brazil.

LEPTODACTYLUS LATRANS (Criolla Frog). **PREDATION.** *Leptodactylus latrans* has a wide distribution in South America, occurring east of the Andes from Venezuela to Argentina (Heyer et al. 2010. IUCN. Red List of Threatened Species. Ver. 2010.1). The species inhabits a wide variety of environments including

open habitats in dry areas, tropical rainforests and disturbed areas (Izecksohn and Carvalho e Silva. 2001. Amphibians of Rio de Janeiro, Editora UFRJ, Rio de Janeiro, RJ, 148 pp.). Formerly known as *L. ocellatus* this species was renamed by Lavilla et al. (2010. Zootaxa 2346:1–16). The only record of predation on tadpoles of *L. latrans* refers to the Great Kiskadee (*Pitangus sulphuratus*; Vaira and Coria 1994. Herpetol. Rev. 25:118). There are no records of predation of *L. latrans* tadpoles by invertebrates. At 2120 h on 27 Oct 2009 we observed two predation events of *L. latrans* tadpoles by aquatic invertebrates. The observations were made in wetland habitat associated with a coastal sand dune (32.1654°S, 52.1523°W, Corrego Alegre, sea level) in the municipality of Rio Grande, RS, southern Brazil. Both events were observed simultaneously in a school of tadpoles in a temporary pond colonized by macrophytes (mainly *Juncus acutus* and *Spartina ciliata*). One of the tadpoles (21 mm body length) was preyed upon by a juvenile aquatic spider (*Diapontia* sp., Lycosidae) and the second tadpole (23 mm body length) by a juvenile water-bug (*Belostoma* sp., Belostomatidae). Most amphibians have a close dependence on water bodies for reproduction, thus making them vulnerable to aquatic predators (Toledo 2003. Phyllomedusa 2:105–108; Fulan and Almeida 2010. Acta. Sci. Biol. Sci. 32:121–124). This observation adds two new predators of *L. latrans* suggesting that the role of invertebrates in the population dynamics of anurans is still insufficiently known, especially in the Neotropics. Tadpoles were deposited in the Collection of the Laboratório de Ecologia de Vertebrados Terrestres of FURG (AMRG46; AMRG47). We thank CNPq and Fapergs for financial support and ICMBio for collecting permits.

LITHOBATES AREOLATUS CIRCULOSUS (Northern Crawfish Frog). **PREDATION.** Raccoons (*Procyon lotor*) are known to consume a wide variety of prey items. They often forage at the edge of shallow water in search of their preferred prey, crayfish (Zeveloff 2002. Raccoons: A Natural History. Smithsonian Institute Press, Washington, D.C. 200 pp.). Amphibians typically do not constitute a large part of their diet. Zeveloff (2002, *op. cit.*) examined raccoon scat and found that 9% was composed of Tiger Salamander (*Ambystoma tigrinum*) remains. Whitaker and Mumford (2009. Mammals of Indiana. Indiana Univ. Press, Bloomington. 661 pp.) examined the stomach contents of 41 raccoons in Indiana and found that amphibians composed 1.7% of the raccoons' diet; both Green Frog (*Lithobates clamitans*) and Fowler's Toad (*Anaxyrus fowleri*) remains were identified. Wright (1966. Herpetologica 22:127–128) witnessed a raccoon kill and eat five Colorado River Toads (*Anaxyrus alvarius*). The raccoon avoided consuming the toxic parotoid glands by turning the animals over and eating the viscera though the anterior abdominal wall. Schaaf and Garton (1970. Herpetologica 26:334–335) reported similar findings in which raccoons preyed upon American Toads (*Anaxyrus americanus*) and often left the head and the upper back.

Parris and Redmer (2005. *In* Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 526–528. Univ. California Press, Berkeley) state that natural predators of Crawfish Frogs (*Lithobates areolatus*) are unknown. Here we report the first known incidents of raccoon predation on Crawfish Frogs, one in Indiana, one in Illinois. During a telemetry study in southwestern Indiana, an adult male Crawfish Frog was found freshly dead the morning of 2 April 2010 along the edge of a breeding wetland where it had migrated the week before. All that remained was the top of the skull and the dorsal skin. The previously intraperitoneally implanted transmitter was a meter away, and within 50 cm, along the shoreline, were fresh raccoon tracks. On 20 March 2010, a recently predated adult male Crawfish Frog was observed at a breeding wetland in southern Illinois. The carcass consisted of a single, nearly-complete piece of skin connected to the top of the skull. The uneaten skin, which included the vocal sacs, was comprised of the dorsum, both sides, most of the venter, and one hind limb. The frog had the appearance of having been skinned.

Crawfish Frog skin, similar to that of toads, is "studded with numerous glandular warts" (Goin and Netting 1940. Ann. Carnegie Mus. 38:137–168); and like several other species of ranids, secretes antimicrobial peptides from granular glands (Ali et al. 2002. Biochimica et Biophysica Acta 1601:55–63). It is possible that skin secretions are distasteful and raccoons avoid eating the skin of Crawfish Frogs, similar to their behavior when preying upon toads.

LITHOBATES CATESBEIANUS (American Bullfrog). **DIET.** The American Bullfrog was introduced in Brazil in the 1930s for commercial breeding. However, escapes from farms and intentional introductions have allowed this species to establish invasive populations in wild habitats, especially in the Atlantic Rainforest (Giovanelli et al. 2008. Biol. Invasions 10:585–595). Here we report data on the diet of the American Bullfrog obtained by stomach content analysis of 50 specimens collected in a reservoir located in Viçosa (20.75764°S, 42.86075°W), Minas Gerais State, southeastern Brazil. The site is known as Represa do Belvedere, and is composed of a group of small connected dams surrounded by a secondary forest fragments and a grassplot. The dams have abundant aquatic vegetation, mostly *Salvinia* sp. and Nympheaceae.

American Bullfrogs were collected during September–December 2003. After collection, specimens were fixed in 10% formalin and preserved in 70% alcohol; SVL was measured to the nearest 0.05 mm and the stomach contents tabulated. Prey items were identified to the lowest known taxonomic level; plant remains were considered to be accidently ingested.

Only 4 individuals (8%) had empty stomachs, and 16 (32%) had nothing but undetermined remains in their stomachs. Plant remains were found in 22 stomachs (44%), and two individuals

Undetermined remains	0	0	16	36.36
Plant material	0	0	21	45.65

had only plant material in the stomach. Thirty-four individuals (68%) had at least one identifiable prey in their stomachs, and prey number by frog varied from 1–16 (mean ± SD: 3.47 ± 3.07). The majority of the individuals measured (N = 28; 56%) were <50 mm SVL (range: 36.8–48.8; 43.92 ± 3.0). Sixteen frogs were between 51.5 and 84.2 mm SVL (65.65 ± 10.81), and the remaining six frogs were >90 mm SVL (range: 90.10–116.05; 100.96 ± 9.05).

Among the 114 prey items identified, the most common were ants, adult Coleoptera, and Heteroptera which represented 52.64% of the total prey ingested (Table 1). Besides these three insect groups, non-ant hymenopterans, naiads of Odonata, and anurans were also frequent prey items (occurring in >10% of the samples). Insects dominanted the diet likely due to the small size of the majority of frogs. These data add *Scinax fuscovarius* to the list of anurans reported as prey of the invasive American Bullfrog not reported by Silva et al. (2009. S. Am. J. Herpetol. 4:286–284).

We thank Mário R. Moura for laboratory assistance and Henrique C. Costa for useful suggestions on the manuscript.

LITHOBATES SYLVATICUS (Wood Frog). **EGG PREDATION**. Predation by tadpoles on eggs and larvae of heterospecifics has been reported for a number of amphibian species (Ehrlich 1979. Bull. Maryland Herpetol. Soc. 15:25–26; Kiesecker and Blaustein 1998. Conserv. Biol. 12:776–787; Petranka et al. 1994. Copeia 1994:691–697). Among these are tadpoles of large-bodied ranids, including Bullfrogs (*Lithobates catesbeianus*) and Green Frogs (*L. clamitans*), which can overwinter in permanent wetlands and pose a serious threat to the reproductive success in pond-breeding amphibians. Vasconelos and Calhoun (2006. Wetlands 26:992–1003) reported that colonization by *L. clamitans* drastically reduced the number of emerging *L. sylvaticus* juveniles in restored wetlands. Here I report daily observations of predation on communal egg masses of *L. sylvaticus* by *L. clamitans* tadpoles contributing to total reproductive failure in a stormwater retention pond.

On 13–15 March 2010, *L. sylvaticus* breeding and oviposition occurred in a stormwater retention pond in suburban Owings Mills, Maryland, USA (39.425758°N, 76.813538°W). This pond typically dries in late summer, but significant rain during 2009 created a permanent water source allowing *L. clamitans* to successfully overwinter in the pond. A complete census of *L. sylvaticus* egg masses was conducted on 16 March and 21 total egg masses were identified: 16 in a communal mass in the northernmost section of the pond ("N Mass") and five in a separate communal mass in the easternmost section of the pond ("E Mass"). On 17 March at 2100 h, 40–60 large ranid tadpoles were observed feeding voraciously on eggs deposited in the deepest area of N Mass (ca. 60 cm water depth). On 18 March, 14.5 egg masses remained, and ca. 12.5 partially intact masses were present on 19 March at N Mass; all of which were deposited in the shallow margin of the pond. During that survey predation was first observed on E Mass eggs by 20–30 tadpoles, and only 4 partial egg masses remained. At this time no remaining eggs had developed past Gosner Stage 17, so it is unlikely that any embryos had successfully developed to free-swimming larvae (Gosner 1960. Herpetologica 16:183–190). The final survey was conducted on 20 March, four days after the first census, when only one egg mass was located at each of the two communal areas. Both egg masses had become partially stranded on woody vegetation as the pond's water level dropped, though lower remnants of each egg mass were still submerged and being consumed by ca. 20 tadpoles.

On 20 March, ten tadpoles were collected and euthanized for further analysis. All tadpoles were identified as *L. clamitans* in Gosner stages 30–37 and dissected for evidence of egg predation. Jelly coating was found in the tadpoles' guts but no discernable

embryos were discovered. Therefore, it is unknown if *L. clamitans* tadpoles were feeding exclusively on the jelly coating or on the embryos too, though no exposed embryos were observed in the general areas of the communal masses. My observations suggest that this pond might serve as an ecological trap for *L. sylvaticus* following abnormally wet years due to predation by overwintered *L. clamitans* tadpoles.

ODONTOPHRYNUS CARVALHOI (Carvalho's Escuerzo). **DEFENSE**. Amphibians can reduce the chances of being eaten either by avoiding being found by a predator or by avoiding being consumed once they have been found (Wells 2007. The Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago, Illinois. 608 pp.). During a study of anuran diet in the Serra de Baturité, a relictual area of Atlantic Forest in the State of Ceará, northeast Brazil, between March and October 2009, we observed several defensive responses by *Odontophrynus carvalhoi*, a poorly studied leaf litter frog restricted to northeastern Brazil (Frost 2009. Amphibian Species of the World: an Online Reference. Ver. 5.3, accessed 16 October 2009). Electronic database accessible at http://research.amnh.org/vz/herpetology/amphibia/ American Museum of Natural History, New York). The first defensive response observed in all *O. carvalhoi* (N = 20) was to flee in response to the approach of the collector. However, when captured, all individuals inflated their bodies, increasing their width considerably. One individual (SVL 69.8 mm) increased its body width almost 40% (36.4 to 50.9 mm) between capture and after having being handled for one minute. While inflated they would lock their mouths very tightly, making it difficult to open them in comparison with individuals of other species included in the same study, including Bufonidae and Leptodactylidae. Some individuals (N = 8), after being stomach-flushed, remained motionless with their legs held close to their bodies. This behavior, interpreted as "death-feigning"(Abbadic-Bisogno et al. 2001 Herpetol. Rev. 32:247), would persist after being placed on the ground with their belly up. They would remain in this position for a variable period of time (10 sec to 5 min), after which they would flip themselves with a fast kick against the substrate. The act of inflating the body to look bigger has been reported for many anurans and is believed to discourage attack by predators or make ingestion more difficult, especially by snakes that swallow their prey whole. Death-feigning has also been reported for many anurans and although its significance remains poorly understood, we believe that it would represent a defense mechanism against visually oriented predators that consume live prey. *Odontophrynus carvalhoi* seems to have a diverse behavioral repertoire to avoid predation, besides its cryptic coloration. Those behavioral responses act in different steps of the predation process and probably vary according to the predator and to other variables of the environment. Some of the collected individuals are deposited at the Laboratório de Zoologia Experimental.

We thank Fundação Cearense de Apoio a Pesquisa (FUNCAP) for the fellowship granted to LBMB.

FIG. 1. *Odontophrynus carvalhoi* inflated after being manipulated. Notice transparency of skin.

PHRYNOHYAS VENULOSA (Milky Tree Frog). **PREDATION**. *Phrynohyas venulosa* is a large and common hylid frog occurring in Middle and South America. It uses a poisonous skin secretion as a defense against predators. This secretion can produce extreme irritation, swelling, and pain if rubbed in the eyes or mucus membranes (Savage 2002. The Amphibians and Reptiles of Costa Rica. A Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). Here I offer an eyewitness account of a *Phrynohyas venulosa* that actively and manually transferred skin secretions onto a predatory snake.

On 9 Dec 2007 I was guiding a group of birdwatchers in the Cano Negro area in Costa Rica. Near the river, in an agricultural area bordering a small forest, we were standing on a road next to a couple of large, free standing trees, when we heard a rustling noise above our heads. A few seconds later, a Green Parrot Snake (*Leptophis ahaetulla*), ca. 1.5 m total length, fell from a tree and landed on a piece of barbed wire that was nailed to the tree. While still hanging on the wire, we observed the *L. ahaetulla* to have an adult *P. venulosa* in its mouth. The *P. venulosa* was held by its left front leg and while struggling to get loose it emitted a large amount of white mucus from its upper side. While it tried to control its position with its right arm, the *P. venulosa* frantically moved its legs over its back to the head of the *L. ahaetulla*. With each movement the frog smeared mucus from its back towards the snake's head (Fig. 1A). These movements seemed to alter the state of the mucus, because the mucus hardened and stiffened, forming tough threads like chewing gum, while the untouched mucus on the head of the *P. venulosa* was fluid. In about two minutes, the head of the *L. ahaetulla* received more of the rubbery mucus. The mucus seemed to shrink while drying, making it harder for the *L. ahaetulla* to manipulate and see its prey. At some

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1A. About one minute into the attempted predation of a *Phrynohyas venulosa* by a *Leptophis ahaetulla*: fresh secretion is still coming off the frog's back. Two coils of dried secretion can clearly be seen tightly wrapped around the snout of the snake, limiting the movements of its mouth and obscuring its view.

FIG. 1B. About one minute after the predation attempt: by rubbing its head against treebark and by chewing movements of its jaws, the snake got rid of most of the secretion. The last coil of dried secretion is just hanging on, including a big chunk inside the snake's mouth.

point it appeared as if the head of the *L. ahaetulla* was tightly bound with plastic rope. Suddenly the *P. venulosa* freed itself and hopped to safety. The *L. ahaetulla* was still hanging from the barbed wire and trying to get rid of the hardened mucus. The mucus had accumulated mainly on the snake's nose, around its head, and in its mouth and was very sticky and tough. The *L. ahaetulla* had to rub its head against the tree and move its jaws horizontally and vertically again and again to remove it. After about two minutes the *L. ahaetulla* got rid of most of it, except for a big chunk in its mouth. Then it became aware of our presence and moved up the tree. When it reached a height of 3 m, its mouth seemed fully free of dried mucus.

It appeared as though the *P. venulosa* was deliberately shoving the mucus towards the snake's head, as its feet collected mucus when moving towards the snake. I am unaware if there are reports of poisonous amphibians that actively transfer their skin secretions, but that appears to be the case in this observation.

PLATYMANTIS VITIANA (Fiji Ground Frog). **FROGLET MORPHOLOGY.** *Platymantis vitiana* is an endangered anuran found only on four small outer islands in Fiji including Viwa, Taveuni, Gau, and Ovalau. On Viwa Island (a 60-ha island, 30 km NE of Suva and 0.95 km from mainland Viti Levu, Fiji), *P. vitiana* shares its natural habitat with invasive *Bufo marinus*. *Bufo marinus* is a prolific breeder while *P. vitiana* is a seasonal breeder (Narayan et al. 2010. Gen. Comp. Endocrinol. 166:172–179). Eradication plans for *B. marinus* on Viwa include chemical use and trapping of toadlets and adults. As a precautionary conservation measure, translocation of a sub-population of *P. vitiana* adults and froglets will be necessary prior to eradication of *B. marinus*. In this process and during eradication, misidentification of *B. marinus* toadlets with froglets of *P. vitiana* is likely to affect the *P. vitiana* population and also shadow the outcome of the eradication programs. Therefore, we attempted to find morphological features of *P. vitiana* froglets for rapid identification in the field.

A clutch of *P. vitiana* eggs was monitored on Viwa Island up to hatching of froglets on 12 Dec 2007. Simultaneously, tadpoles of *B. marinus* were also monitored in a nearby natural pond on Viwa Island up to four weeks.

Bufo marinus eggs typically underwent a tadpole metamorphosis while eggs of *P. vitiana* metamorphosed directly into newly hatched froglets without a tadpole stage. Morphologically, the hatchlings of both *P. vitiana* and *B. marinus* are of similar size (mean = 8 mm SVL) and have the second digit of both the anterior and posterior limbs longer than the rest of the digits. Each anterior limb has four digits while each posterior limb has five digits. Furthermore, the hatchlings of both species have blackish-brown or greenish striped patterns on the upper surfaces of both anterior and posterior limbs. However, a morphological feature diagnostic of *P. vitiana* froglets was identified. A butterfly pattern of five brown raised warts on the dorsal head region, forming a circle with one brown raised wart in the center, was observed in all *P. vitiana* froglets (Fig. 1). However, metamorphs of *B. marinus* of similar age only have greenish raised warts distributed along the head–vent margin.

These morphological features thus can be used to identify metamorphs of *P. vitiana* in the field and help to avoid misidentification with those of invasive *B. marinus*. This study is the first record of morphological characteristics of *P. vitiana* froglets and

PROCERATOPHRYS MELANOPOGON (Black-bearded Horned Leaf Toad). **DEFENSIVE BEHAVIOR.** *Proceratophyrs melanopogon* is a small to medium-sized cycloramphid anuran that belongs to the *Proceratophyrs appendiculata* complex (Prado and Pombal 2008. Arq. Zool. 39:1–85). Species within this complex are characterized by the presence of palpebral appendages and cryptic coloration resembling fallen leaves (Prado and Pombal 2008, *op. cit.*; Toledo and Haddad 2009. Int. J. Zool. 2009:1–12). *Proceratophyrs melanopogon* mainly inhabits leaf litter on the forest floor in Atlantic Rainforest areas of southeastern Brazil (Izecksohn et al. 1998. Rev. Univ. Rural, Sér. Ciênc. Vida 20:37–54; Prado and Pombal 2008, *op. cit.*).

On 4 Dec 2009 at 1430 h, we observed defensive behavior displayed by *P. melanopogon* upon capture. After grasped with the hand, the specimen flattened its body and stretched out its legs, keeping this position until being released on the ground (Fig. 1). The observation took place near a permanent pond in Serra do Brigadeiro State Park, an area of montane rainforest in municipality of Araponga, state of Minas Gerais, Brazil (20.7219ºS, 42.4786ºW, elev. 1320 m, SAD1969).

This defensive behavior has been called stiff-legged (Sazima 1978. Biotropica 10:158) and was reported for other horned leaf toads, including *P. appendiculata* (Sazima 1978, *op. cit.*) and *P. boiei* (Toledo and Zina 2004. Herpetol. Rev. 35:375). Similar behaviors for other leaf-litter anurans (e.g., *Dendrophryniscus leucomystax, D. brevipollicatus*, *Scythrophrys sawayae*, *Stereocyclops parkeri*) has been regarded as behavioral convergence given that leaf-litter inhabiting species are subject to similar predation pressures (Bertoluci et. al 2007. Alytes 25:1–2; Garcia 1999. Herpetol. Rev. 30:224; Sazima 1978, *op. cit.*; Toledo and Zina 2004, *op. cit.*).

FIG. 1. *Proceratophrys melanopogon* (25.9 mm SVL) from Minas Gerais, Brazil displaying stiff-legged defensive behavior.

The adaptive value of this behavior might be in enhancing crypsis among fallen leaves, confusing visually oriented predators (Sazima 1978, *op. cit.*; Toledo and Zina 2004, *op. cit.*), and/or inhibiting ingestion by predators (Angulo and Funk 2006. Herpetol. Rev. 37:203–204; Azevedo-Ramos 1995. Rev. Bras. Biol. 55:45–47).

We thank the Instituto Estadual de Florestas (IEF) and Universidade Federal de Viçosa for logistic support, and Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for fellowships granted to MRM.

RHINELLA MARGARITIFERA (NCN). **PARASITES.** The *Rhinella margaritifera* complex is widely distributed in Latin America, occurring throughout the Amazon Basin and parts of Panama (IUCN, Conservation International, and NatureServe 2004. Global Amphibian Assessment. <www.globalamphibians.org>. Accessed 03 Dec 2004). Although amphibians are known to be parasitized by larvae of numerous fly species, this is a poorly studied area of amphibian biology. In Europe, North America, and India, amphibians are commonly attacked by larvae of several blow flies (Calliphoridae) and flesh flies (Sarcophagidae; Bolek and Coggins 2002. J. Wildl. Dis. 38:598–603; Dasgupta 1967. Parasitology 52:63–66; James and Maslim 1947. J. Washington Acad. Sci. 37:366–368; Strijbosch 1980. Oecologia 45:285–286), and in Australia amphibians are infected with larvae of grass flies (Chloropidae; Schell and Burgin 2001. J. Parasitol. 87:1215–1216).

In Neotropical regions, cases of flesh fly parasitism in anurans have been recorded from *Atelopus* spp. in Costa Rica (Crump and Pounds 1985. Parasitology 75:588–591), *R. granulosa* in Venezuela (Lopes and Vogelsang 1953. An. Acad. Brasil. Ciências 25:139–143), *Rana catesbeiana* in Brazil (Souza et al. 1990. Mem. Inst. Oswaldo Cruz 84:517–518), *Eleutherodactylus* sp. in Panama (Dodge 1968. Ann. Entomol. Soc. America 61:421–450), *Proceratophrys* in Brazil (Lopes 1981. Rev. Brasil. Entomol. 41:149–152), and *Epipedobates* spp. (Hagman et al. 2005. Phyllomedusa 4:60–73). Here, we offer a first report of parasitism of *R. margaritifera* by flesh flies.

On 16 August 2007 at 1000 h, we found an adult *R. margaritifera* (42.9 mm SVL, 6 g) in Floresta Nacional de Caxiuanã, near the municipality of Portel (1.96000°S, 51.6152778°W; elev. 20 m), State of Pará, Brazil. The specimen was hidden within the dry leaves and twigs of *terra firme* forest ground. During preservation we observed 21 flesh fly larvae leaving the body of *R. margaritifera* through the cloaca. The larvae were preserved in 70% alcohol.

We deposited the *R. margaritifera* and flesh fly larvae in the herpetological (MPEG 21938) and entomological collections, respectively, of the Museu Paraense Emílio Goeldi, Belém, State of Pará, Brazil. Marinus S. Hoogmoed verified identification of the frog.

SCAPHIOPUS COUCHII (Couch's Spadefoot). **PREDATION**. Predation on adult *Scaphiopus couchii* has rarely been reported in the literature, despite numerous studies of predation on larvae of this species and other spadefoots (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York. 670 pp.). On 1 May 2008 a road-killed American Badger (*Taxidea taxus*) was salvaged from US Hwy 87 in Tom Green Co., Wall, Texas, USA (31.371819°N, 100.313141°W; WGS 84). Habitat in the area adjacent to the highway is primarily cultivated cotton fields with small areas of grassland. Analysis of stomach contents of the badger revealed the remains of four adult *S. couchii*, in addition to one Texas Spotted Whiptail (*Aspidoscelis gularis*) and three unidentified juvenile rodents. Toxic skin secretions of the spadefoots apparently were no deterrent to the predator. The multiple *S. couchii* taken by the badger suggests a high activity for spadefoots at that time. On 27 April there had been thunderstorms with accumulations of rain of 1.24 cm at the nearest weather station at San Angelo Airport. This precipitation might have been sufficient to bring about reproductive activity for adult spadefoots and the badger opportunistically preyed on these. Published accounts of the diet of *Taxidea taxus* rarely include amphibians, but to our knowledge only unidentified *Rana* species and Eastern Tiger Salamanders (*Ambystoma tigrinum*) have been reported (Errington 1937. J. Mammal. 18:213–216; Snead and Hendrickson 1942. J. Mammal. 23:380–391; Sovada et al. 1999. Amer. Midl. Nat. 142:410–414). Specimens have been deposited in the Collections of Amphibians and Reptiles, Angelo State Natural History Collections, Angelo State University, as ASNHC 14270 (*S. couchii*) and ASNHC 14271 (*A. gularis*).

SCAPHIOPUS COUCHII (Couch's Spadefoot). **DEVELOPMENTAL MORPHOLOGY**. *Scaphiopus couchii* from the deserts of the American southwest exhibit the shortest larval period duration known among amphibians, developing from hatching to forelimb emergence in as little as 8 days (Newman 1987. Oecologia 71:301–307). Here, we report a morphological observation representing a contributing mechanism to achieve short larval periods, namely the elimination from its ontogeny of Gosner developmental stages 24 and 25 (Fig. 1; Gosner 1960. Herpetologica 16:183–190). Gosner Stage 23 (G23) is defined by the presence of external gill filaments on both sides of the body. At G24, the operculum (skin covering) covers the right gill filaments. At G25, the operculum covers the gill filaments on both sides. At G26, the hind limb buds appear. In *S. couchii* (two-day-old embryos from adults collected in Cochise Co., Arizona USA), the hind

FIG. 1. *Scaphiopus couchii* within a day after hatching showing developing hind limb bud and external gill filaments on the right side of the body (gills and hind limb bud are present on left side also, but not visible here). This developmental stage is not compatible with the Gosner staging table.

limb buds became visible prior to operculum formation on either side of the body (Fig. 1). This developmental situation does not occur in the spadefoot relatives, *Spea multiplicata* or *Pelobates cultripes*, which follow the typical Gosner stages. Other species of *Scaphiopus* should be examined. We did not observe any instance in *S. couchii* where neither the right and left nor just the right gill filaments were covered by the operculum in the absence of hind limb buds. However, G23 individuals were observed, where right and left external gills were visible in the absence of hind limb buds. Interestingly, *S. couchii* still has G26, indicating a lag in hind limb growth after its first appearance at G23. This lack of limb bud growth during operculum formation may correspond to the time lag in stage advancement during G26 in *S. multiplicata* (Buchholz and Hayes 2002. Copeia 2002:180–189). It appears that hind limb development in *S. couchii* has been heterochronically shifted to initiate at an earlier stage (from G26 to G23). The elimination of developmental stages may enable *S. couchii* to achieve subsequent stages at earlier time points, contributing to its extremely short larval periods. This divergence of *S. couchii* from the typical developmental sequence found in anuran tadpoles precludes comparing *S. couchii* to other species at these developmental stages. The developmental modification reported here accompanies two other evolutionary modifications underlying the short larval periods in *S. couchii*. First, *S. couchii* has extremely rapid cell division cycles during the embryonic period (Zweifel 1968. Bull. Am. Mus. Nat. Hist. 140:3–64), perhaps due to their relatively small genome size (www.genomesize.com). Second, increased levels of thyroid hormone tissue content and heightened sensitivity and responsivity to thyroid hormone contribute to their accelerated metamorphic period (Buchholz and Hayes 2005. Evol. Develop. 7:458–467).

Submitted by **DANIEL R. BUCHHOLZ** and **AMY R. HOLLAR**, Department of Biological Sciences, University of Cincinnati, Cincinnati, Ohio 45221, USA (e-mail: buchhodr@ucmail.uc.edu); and **CRIS LEDON-RETIG**, Department of Biology, University North Carolina, Chapel Hill, North Carolina 27599, USA.

SCINAX FUSCOVARIUS (NCN). **PREDATION**. Snakes are commonly known to prey on anurans (Michaud and Dixon 1989. Herpetol. Rev. 20:39–41) including species of *Scinax* (Bernarde et al. 2000. Rev. Brasil. Biol. 60:695–699). At 2000 h on 26 Nov 2005, at Fazenda Jatobá (Buritizeiro Municipality, State of Minas Gerais, Brazil; 17.1269444°S, 44.8788889°W), we found an

adult *Xenopholis undulatus* (300 mm SVL, not collected) during a heavy rainfall, foraging among the wet grass near a temporary pond. When captured, the snake regurgitated an adult *Scinax fuscovarius* (35.6 mm SVL; AAG-UFU 3574, Museu de Biodiversidade do Cerrado, Minas Gerais, Brazil). This is the first record of *X. undulatus* preying on an anuran. Only *X. scalaris* is known to prey on anurans (Cunha and Nascimento 1993. Ofídios da Amazônia. As Cobras da Região Leste do Pará. Boletim Museu Paraense Emílio Goeldi 9:1–191). Other anurans present in the area that could be potential prey of *X. undulatus* and other snake species include *Pseudopaludicola mystacalis, Dendropsophus cf. marmoratus, Physalaemus centralis*, and *P. cuvieri*.

Submitted by **MARCELO N. DE. C. KOKUBUM,** Programa de Pós-Graduação em Desenvolvimento e Meio Ambiente (PRODEMA), Universidade Federal do Rio Grande do Norte, Brazil and Laboratório de Ecologia e Sistemática de Anuros Neotropicais, Instituto de Biologia, Universidade Federal de Uberlândia, Minas Gerais, Brazil (e-mail: mnckokubum@unb.br); and **NATAN MEDEIROS MACIEL,** Laboratório de Comportamento Animal e Herpetologia, Departamento de Ecologia, Instituto de Ciências Biológicas, Universidade Federal de Goiás, Brazil.

SCINAX FUSCOVARIUS (Snouted Treefrog). **PREDATION.** *Scinax fuscovarius* are frogs of medium size, widely distributed in Brazil and also in Paraguay, Argentina, Bolivia, and Uruguay (Haddad et al. 2008. Anfíbios da Mata Atlântica: Guia dos Anfíbios Anuros da Mata Atlântica. São Paulo. Editora Neotropica. 244 pp.; Frost 2010. Amphibian Species of the World: an Online Reference. Version 5.4 [8 April 2010]. Electronic database accessible at http://research.amnh.org/vz/herpetology/amphibia/ American Museum of Natural History, New York). During the day the species can be found sheltered in burrows, crevices, trees, soil, and human construction (Araujo et al. 2009. Biota Neotrop. 9:77–98).

Domestic Cats (*Felis catus*) have been associated with humans for thousands of years and have accompanied humans to nearly every part of the world (Brickner 2003. Tel Aviv University report. http://www.tau.ac.il/lifesci/zoology/members/yom-tov/inbal/cats.pdf). Because they form a domestic species distinct from their wild ancestral species, Domestic Cats are considered to be an exotic, or non-native, species in all environments in which they occur (Dauphiné and Cooper 2009. Proc. Fourth International Partners in Flight Conference, pp. 205–219). Because of their ability to overwhelm existing native species and natural ecosystem processes in environments in which they have been introduced, Domestic Cats are classified as an invasive species (Dauphiné and Cooper 2009, *op. cit.*). Invasive species, particularly predators, together with habitat destruction, have been a major cause of declines and extinctions of native species throughout the world for the past few centuries (Clavero and García-Berthou 2005. Trends Ecol. Evol. 20:110). Here we report the predation of a juvenile *S. fuscovarius* by a juvenile male *F. catus*.

On 17 April 2010 at 1900 h, in a back yard of a house at the Araçatuba city, São Paulo State, a *F. catus* was observed preying upon a juvenile *S. fuscovarius*. The frog was ingested by the cat, and thus we were unable to collect the frog. The next day, we found the remains of the frog along with ants. *Felis catus* is considered a generalist mammal, including in its diet insects such as bumblebees and grasshoppers, rodents, amphibians, reptiles, and ground nesting and ground roosting birds which are particularly vulnerable (Ogan and Jurek 1997. *In* Harris and Ogan [eds.], Mesocarnivores of Northern California: Biology, Management, and Survey Techniques, workshop manual, pp. 87–92. The Wildlife Society, California North Coast Chapter, Arcata, California). However, this is the first record of *Felis catus* as a predator of *S. fuscovarius.*

SPEA INTERMONTANA (Great Basin Spadefoot). **ALGAL SYMBIOSIS.** The occurrence of epizoic algal symbiosis has been reported in tadpoles of the American Toad (*Bufo americanus)* found in Arkansas and Missouri, USA (Drake et al. 2007. Herpetol. Rev. 38:435–436; Tumlison and Trauth 2006. Herpetol. Cons. Biol. 1:51–55), as well as those of the Gray Treefrog (*Hyla versicolor*) and the Cricket Frog (*Acris crepitans*) in Arkansas, USA (Tumlison and Trauth 2006, *op. cit.*), and was surmised to be more widespread geographically and among species with aquatic anuran larvae. Observations reported herein indicate that is indeed the case. On 15 June 2009, at 1430 h, DLD observed tadpoles of *Spea intermontana* in three natural pools and tanks in the Grand Wash Gorge, Capital Reef National Park, Wayne Co., Utah, USA, bearing bright green patches on the dorsal and lateral sides of their bodies, and tails. The ambient temperature at time of observation was 26°C with partly cloudy skies; water temperature in the large tank was 22°C. All three tanks were within 50 m of one another in the same sand and bedrock drainage.

The two smaller pools in which tadpoles were observed were 2 m diameter, 0.3–0.4 m deep, and 3 m x 6 m, max. depth 0.3 m, and had clear water and a sandy substrate with abundant algal growth. *Triops* (tadpole shrimp), fairy shrimp (Chirocephalidae), and hydrophilid beetle larvae were present, as were a few larger, later stage, non-cannibalistic morphs of *S. intermontana* tadpoles. DLD examined six of the tadpoles of *S. intermontana* (Gosner stages 34–36 [Gosner 1960. Herpetologica 16:183–190],

FIG. 1. Tadpoles of *Spea intermontana*, Wayne Co., Utah, USA, with varying degrees of epizoic algae seen as green patches on the skin.

total length 7–8 cm), in the smaller pool, four of which exhibited extensive algal patches, two did not (Fig. 1).

The largest of the tanks encountered at the site measured about 6 m in diameter and was 1–1.5 m deep. Algae were abundant on the bedrock sides of the tanks, although the bottom of the tank was not visible. Hundreds of cannibalistic and omnivorous tadpoles of *S. intermontana* were present in these tanks, as were some tadpoles of *H. arenicolor*. Bright green patches were visible on both morphotypes of the larvae of *S. intermontana*, but were not visible on those of *H. arenicolor*. Many of the larger, later stage tadpoles of *S. intermontana* in this tank exhibited extensive green patches, especially on the tails and laterally and dorsally on the body, but smaller, earlier stage tadpoles (Gosner stages 30–33, total length ca. 4–5 cm) did not appear to have algal colonies on their skin.

Tadpoles were collected and preserved in 10% formalin, then examined by SET with a scanning electron microscope. Examination of the green patches revealed a biflagellated alga, *Chlorogonium*, which was found on the tadpoles of *Bufo americanus* from Missouri and Arkansas. This finding adds a new species, family (Pelobatidae), and ecoregion (Great Basin Desert) to the list of larval anurans with algal symbionts and their distribution. There will surely be more amphibian species and the occurrence more ubiquitous as researchers continue to take notice of such phenomena.

We thank Capitol Reef National Park for the allowing collection of the specimens and R. Altig for providing comments which improved this manuscript.

TOMOPTERNA CRYPTOTIS (Cryptic Sand Frog). **ALBINISM.** While conducting research on Turkana conceptions of snakes, we observed an albino adult male *Tomopterna cryptotis* (SVL 45 mm) calling from a temporary pool left from torrential rains from the previous week, where the A1 "Lodwar" road

Fig. 1. Adult male albino *Tomopterna cryptotis*. Photographed in the field in Lokichar, Turkana District, Northwest Kenya, 8 January 2009.

crosses the Lokichar River near the town of Lokichar, Turkana District, northwest Kenya. The specimen had red eyes with blood vessels visible through the skin (Fig. 1). Only the terminal tips of the warts exhibited light yellow coloration, therefore, this frog could be considered a partial albino with xanthophores (Dyrkacz 1981. SSAR Herpetol. Circ. 11, 131 pp.), otherwise, the specimen was entirely white with a pinkish tinge where the typical coloration would have exhibited very dark blotches. Over 50 other *T. cryptotis* with typical coloration were observed, with several pairs in amplexus. Whether this albinism could reduce its chances of getting a mate was not established. Only one other species of anuran was observed, a lone male *Bufo lughensis*. This report corroborates the contention of Sazima and Di Bernado (1991. Mem Inst. Butanantan 53:167–173) that albinism may occur with more frequency in nocturnal or fossorial animals (of which *T. cryptotis* is both), that theoretically are less dependant on camouflage to survive. To our knowledge this is the first report of albinism for the genus *Tomopterna*.

ZACHAENUS CARVALHOI (Carvalho's Bug-eyed Frog). **DEFENSIVE BEHAVIOR**. Amphibians are subject to predation by an array of invertebrates and vertebrates, and are known to display a wide variety of defensive behaviors (Wells 2007. The Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago, Illinois. 1148 pp.). *Zachaenus carvalhoi* is a small leaf-litter frog known from few localities in the Atlantic Forest biome in south-

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. An adult *Zachaenus carvalhoi* (25.3 mm SVL) in death feigning behavior.

eastern Brazil (Motta et al. 2010. Herpetol. Notes 3:85–86). It is categorized as Data Deficient in the IUCN redlist, due to the lack of information on its occurrence and biology. On 19 Feb 2010, an adult *Z. carvalhoi* was captured in a pitfall trap with drift fences, inside a forested area in the Serra do Brigadeiro State Park, an area of montane rainforest in the municipality of Araponga, state of Minas Gerais, Brazil (20.7219ºS, 42.4786ºW, elev. 1380 m, SAD 1969). During handling, the frog displayed a defensive behavior in which it stretched out its four limbs and closed its eyes, keeping this position until being released on the ground (Fig. 1).

Similar defensive behaviors have been described for other leaf-litter frogs including *Dendrophryniscus leucomystax*, *D. brevipollicatus* (Bertoluci et al. 2007. Alytes 25:1–2), *Scythrophrys sawayae*, (Garcia 1999. Herpetol. Rev. 30:224), *Stereocyclops parkeri*, *Proceratophrys appendiculata* (Sazima 1978. Biotropica 10:158), and *P. boiei* (Toledo and Zina 2004. Herpetol. Rev. 35:375), although in these species only their hind legs are stretched out, not all four limbs, as in *Z. carvalhoi*. The observation of this behavior in several leaf-litter anurans suggests behavioral convergence reflecting similar predation pressures (Sazima 1978, *op. cit*.). The adaptive value of this behavior might reside in improving the frog's appearance as fallen or dead leaves, confusing visually oriented predators (Sazima 1978, *op. cit.*; Toledo and Zina 2004, *op. cit.*).

A voucher specimen was deposited in the herpetological collection of Museu de Zoologia João Moojen, Universidade Federal de Viçosa, in Viçosa, Minas Gerais, Brazil (MZUFV 10339). We thank the Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA) and Instituto Estadual de Florestas (IEF) for collecting permits (IBAMA 20857-1, IEF 071/09), the Universidade Federal de Viçosa for logistic support, the Fundação de Amparo à Pesquisa do Estado de Minas Gerais (FAPEMIG, CRA-APQ-02370-09) for financial support, and the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for fellowships granted to MRM.

GYMNOPHIONA — CAECILIANS

GYMNOPIS MULTIPLICATA (NCN). **MATERNAL ATTENDANCE**. Post-birth parental care by a viviparous caecilian has been reported previously only once: altricial young of *Geotrypetes seraphinii* are reported to feed on the skin of the attending maternal female (O'Reilly et al. 1998. Amer. Zool. 38:187A). We report an instance of a maternal female of a viviparous species guarding her recently born young, similar to that of the maternal guarding reported for several oviparous and direct-developing species (e.g., *Ichthyophis glutinosus*: Sarasin and Sarasin 1887. Ergebnisse naturwissenschaftlichen. Forschungen auf Ceylon. C. W. Kreidel's Verlag, Wiesbaden; Breckenridge and Jayasinghe 1979. Ceylon J. Sci. 13:187–202; *Idiocranium russelli*: Sanderson 1937. Animal Treasure. Viking Press, New York. 325 pp.; *Caecilia orientalis*: Funk et al. 2004. Herpetol. Rev. 35:128–130 [a female and two males with a clutch]).

On 16 July 2008, JRM collected an adult female *Gymnopis multiplicata* (MVZ 263798; 363 mm total length; 117 primary annuli, 103 secondaries; each ovary containing many small early vitellogenic ova) and four young *G. multiplicata* (MVZ 263800, 263802, 263804, 263805; total lengths 110–126 mm) under a large log at Rawa Kiamp (15.100°N, 84.4333333°W), Gracias a Dios, at 60 m elev in the Mosquitia of northeastern Honduras. The young were apparently recently born, still having several rows of teeth of fetal morphology on the lower jaw, the labialmost row of very small teeth emerging from the skin of the jaw at the lipline, consistent with the typical aggregation of the rows of fetal teeth before all are shed shortly after birth (Wake 1976. J. Morphol. 148:33–64; Wake 1980. J. Morphol. 166:203–216). The fetal teeth are markedly different (crowns with multiple cusps and different shapes) from the arrow-shaped tooth crowns of the maternal female and other adult *G. multiplicata* (Wake and Wurst 1979. J. Morphol. 159:331–342). The adult was in direct contact with all four young with the adult looped above and around the young, forming a ball. Immediately on exposure, the adult tried to escape by quickly crawling away. The young also tried to escape, but were not as quick as the adult. The young did not follow the adult, but crawled in different directions. All caecilans in the ball were collected. There is no indication that the skin of the female is physically modified or abraded in any way, nor does there appear to be any skin in the mouths of the young, so skin-feeding is unlikely. This is consistent with their relatively large size at birth, the neonates of the direct-developing skin-feeders (*Boulengerula taitanus* and *Siphonops annulatus*) reported being smaller relative to maternal size (Kupfer et al. 2006. Nature 440:926–929; Wilkinson et al. 2008. Biol. Let. 4:358–361).

OSCAECILIA OSAE (NCN). **PREDATION**. The coral snake *Micrurus alleni* and the endemic caecilian *Oscaecilia osae* both occur in the lowland wet rainforest of the National Park Piedras Blancas (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.), which is located in the Pacific lowlands of Costa Rica (Weissenhofer et al. 2008. Cultural and Natural History of the Golfo Dulce Region. OÖ Landesmuseum Linz, Biologiezentrum, Johann-Wilhelm Kleinstraße). The prey of *Micrurus alleni* is comprised largely of the eeliform freshwater fish *Synbrachus marmoratus* and some lizards (Roze 1996. Coral Snakes of the Americas: Biology, Identification, and Venoms. Krieger Publ. Co., Malabar, Florida. 328 pp.). During a visit to the Tropical Research Station La Gamba (www.lagamba.at), a biological field station in the NP Piedras Blancas operated by the University of Vienna, WH observed *M. alleni* preying on the caecilian *O. osae*. Around midday on 8 July 2009 a *Micrurus alleni* was seen to have an *Oscaecilia osae* in its mouth. The observation occurred directly on the "Birds Trail" (Sendero Bajaros), not far from the Esquinas Rainforest Lodge (8.6977778°N, 83.2052778°W, ca. 80 m elev.). The snake was holding the caecilian—which was still alive—in its mouth and was trying to move the prey away from the trail to the forest litter close by. It appeared as though the snake had caught the caecilian with the intention of consuming it. Until this observation, *Micrurus alleni* was not known to prey on the caecilian *Oscaecilia osae*.

TESTUDINES — TURTLES

CHELONOIDIS CARBONARIA (Red-footed Tortoise). **SIZE AND THERMAL BIOLOGY.** From 4–19 June 2010, we had 62 encounters with Red-footed Tortoises on Union Island (St. Vincent and the Grenadines). *Chelonoidis carbonaria* is found throughout much of Central and South America (Ernst and Leuteritz 1999. Cat. Amer. Amphib. Rept. 690:1–6), and populations on West Indian islands might be descendants of ancestors that arrived via natural over-water dispersal, as a consequence of intentional introductions by Amerindians or early colonial Europeans (perhaps for food), more recently transported pets and ornamentals, or some combination thereof (e.g., Censky 1988. Florida Sci. 51:108–114; Powell and Henderson 2005. Iguana 12:62–77). The origin of the Union Island population is unknown.

Tortoises were abundant in a variety of habitats that ranged from coastal scrub and variously disturbed dry forests to dramatically altered situations on the grounds of hotels and in urban areas at elevations ranging from sea level to 258 m (on an island with a maximum elevation of 305 m). Although dogs might take small individuals (e.g., Hodge et al., 2003. The Reptiles and Amphibians of Anguilla, British West Indies. Anguilla Natl. Trust, The Valley), the abundance of tortoises in the Grenadines in general and on Union in particular might be attributable to the fact that local residents scorn them as food because of their willingness to consume fecal matter and carrion (Daudin and de Silva 2007. Appl. Herpetol. 4:163–176).

Carapace lengths of tortoises large enough for accurate determinations of sex were 248–334 mm (301 ± 25.1 mm) for males (N = 11) and 152–330 mm (264 ± 56.9 mm) for females (N = 17). Carapace lengths of ten 6–8 week-old juveniles hatched in an outdoor enclosure were 45–63 mm (55 ± 5.1 mm). Ernst and Leuteritz (1999, *op. cit.*) listed a maximum carapace length of 400 mm for females and 600 mm for males. The smaller maximum sizes of the Union Island turtles are suggestive of insular dwarfism (e.g., Keogh et al. 2007. Evolution 59:226–233), but also might merely reflect food limitations on a xeric island.

We encountered active turtles during the morning (0538–0919 h, N = 6) and afternoon/evening (1500–2256 h, N = 22), suggesting that they avoid the heat of the day (although one individual was active at 1205 h). Unlike most squamates, turtles generally lack a narrow preferred temperature range (e.g., Weathers and White 1971. Amer. J. Physiol. 221:704–710). To test the prediction that tortoises on Union Island did not actively thermoregulate, we used a Fluke model 52 Digital Thermometer with Type K thermocouple (Fluke Corp., Everett, Washington, USA) to record cloacal and adjacent ambient (air) temperatures in the field. We measured cloacal temperatures of 26.0–34.6°C (28.1 ± 1.3°C, N = 19) at air temperatures of 25.3–30.8°C (28.9 ± 1.8°C).

Differences between ambient and cloacal temperatures were -7.0–1.5°C (-0.78 ± 1.44°C), with 30 of 41 records above and two at ambient temperatures.

We also placed nine individuals (carapace length 45–172 mm, 88 ± 56 mm) in a thermal gradient (90 x 30 cm) with extreme temperatures of 24° and 40°C. Although most individuals spent more time near the cooler end of the gradient, possibly because they heat faster than they cool under laboratory conditions (Weathers and White, *op. cit.*), cloacal temperatures after 2 h were 23.9–31.6°C (26.5 ± 2.7°C). The considerable variation in individual temperatures in both the field and the gradient was suggestive of little more than an avoidance of extremely high temperatures.

Permits to conduct research on Union Island were issued by Mr. Brian Johnson, Director, Department of Forestry, St. Vincent and the Grenadines. Protocols were approved by the Avila University Animal Care and Use Committee. Fieldwork was funded by a grant from the National Science Foundation (USA) to Robert Powell (DBI-0851610). All tortoises were released at original sites of capture.

Submitted by **HAYDEN D. HEDMAN**, Department of Ecology and Evolutionary Biology, University of Colorado, Boulder 80301, USA (e-mail: hayden.hedman@colorado.edu); **DEBORAH N. MUÑIZ PAGAN,** Department of Biology University of Puerto Rico, Mayagüez, Puerto Rico 00681 (e-mail: deborah_muniz@hotmail.com); and **ROBERT POWELL**, Department of Biology, Avila University, Kansas City, Missouri 64145, USA (e-mail: robert.powell@avila.edu).

GOPHERUS POLYPHEMUS (Gopher Tortoise). **DIET.** Consuming scat of conspecifics and other animals may provide species of *Gopherus* with symbiotic gut microbes and/or direct nutritional benefits (Bjorndal 1987. Copeia 1987:714–720; Lance and Morafka 2001. Herpetol. Monogr. 15:124–134; Walde et al. 2006. Herpetol. Rev. 37:77–78). In addition to scat of conspecifics, *G. polyphemus* occasionally eats fox (*Vulpes vulpes* or *Urocyon cinereoargenteus*), raccoon (*Procyon lotor*), and rabbit (*Sylvilagus* spp.) feces (Anderson and Herrington 1992. Herpetol. Rev. 23:59; Garner and Landers 1981. Proc. Ann. Conf. S.E. Assoc. Fish & Wildl. Agencies 35:120–134; MacDonald and Mushinsky 1988. Herpetologica 44:345–353). Here, we report a juvenile *G. polyphemus* consuming deer pellets.

At approximately 1700 h (CST) on 4 October 2008, one of us (JRL) observed a 13-month-old *G. polyphemus* at the Camp Shelby Joint Forces Training Center (CSJFTC), Perry Co., Mississippi, USA consume the pellet of a White-tailed Deer (*Odocoileus virginianus*). Upon swallowing the pellet, the young tortoise ate another. Platt et al. (2009. Southeast. Nat. 8:335–346) reported a single deer pellet in the feces of a Florida Box Turtle (*Terrapene carolina bauri*), but to our knowledge, this is the first account of *Gopherus* eating deer droppings. It should be noted that the tortoise in the above observation was head-started in a large outdoor enclosure for most of its first year of life before being released back to its nest site only 10 days prior to our observation.

We thank the Mississippi Army National Guard for their continued support of tortoise conservation efforts on CSJFTC.

KINOSTERNON SONORIENSE (Sonoran Mud Turtle). **PREDATION**. In much of the arid American Southwest, stock tanks (= earthen cattle ponds) are a common landscape feature, and in the Atascosa/Pajarito Mountains, Santa Cruz Co., Arizona, stock tanks that hold water throughout the year often support breeding populations of *Kinosternon sonoriense* as well as populations of invasive American Bullfrogs (*Lithobates* [*Rana*] *catesbeianus*; Jones and Akins, unpubl.). While engaged in a large-scale effort to eliminate Bullfrogs from this landscape, we routinely examined stomach contents of captured frogs, and herein provide the first documented evidence of predation by Bullfrogs on *K. sonoriense*.

On 8 May 2009, 1230–1600 h MST, we removed six large adult Bullfrogs (SVL 150–185 mm) from Yank Tank (31.42534°N, 111.18330°W; datum = NAD 83, 1252 m elev.). Two Bullfrogs, one male and one gravid female (both SVL = 180 mm) had each ingested a juvenile *K. sonoriense* (CL = 56 mm, PL = 47 mm, and CL = 59 mm, PL = 49 mm, respectively). Size and development of plastron annuli suggest these turtles were each in their second year (F. R. Hensley and T. R. Jones, unpubl.). On 18 and 19 August 2009, one of us (CMA) visited two other sites: Salty Tank (31.46360°N, 111.18866°W; 1298 m elev.) and Frog Tank (31.47352°N, 111.19686°W, 1317 m elev.), respectively. At Salty Tank (1525–1615 h MST) four subadult Bullfrogs (SVL 90–95) were removed, one of which (male, SVL = 91 mm, mass = 60 g) contained a hatchling *K. sonoriense* (CL = 23.6 mm, PL = 18.9 mm, mass = 2.11 g). At Frog Tank (1000–1130 h MST), three subadult Bullfrogs (SVL 99–115) were removed, one of which (male, SVL = 115 mm, mass = 135 g) also contained a hatchling *K. sonoriense* (CL = 25.0 mm, PL = 20.4 mm, mass = 2.75 g). The sizes and collection dates are consistent with the conclusion that these two turtles had hatched within a few weeks or less (Stone 2001. Southwest. Nat. 46:41–53; F. R. Hensley and T. R. Jones, unpubl.). Although such predation had been predicted to occur (Schwalbe and Rosen 1999. Sonoriensis 19:8–10), to our knowledge, this is the first documented report of Bullfrog predation on *K. sonoriense*.

In stock tanks in southeastern Arizona with large breeding populations of Bullfrogs we have observed a pattern in which *K. sonoriense* populations almost exclusively consist of large adults (Jones and Akins, pers. obs.), suggesting a lack of recruitment consistent with the predation reported here. This hypothesis was also suggested by Schwalbe and Rosen (1988. pp. 166–173. In Szaro et al. [eds.], Management of Amphibians, Reptiles and Small Mammals in North America, pp. 166–173. U.S. Forest Service Gen. Tech. Rep. RM-166, Fort Collins, Colorado) to explain a similar demographic pattern at San Bernardino National Wildlife Refuge in extreme southeastern Arizona. Thus, although

it might be unsurprising to document Bullfrog predation on yet another species of turtle (e.g., reviews in Bury and Whelan 1984. U.S. Department of the Interior Fish and Wildlife Service Res. Publ. 155. Washington, D.C.; Casper and Hendricks 2005. *In* Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 540–546. University of California Press, Berkeley), the impacts of the predation reported here have important conservation implications. Our data suggest that Bullfrogs can seriously affect population dynamics of relatively small, geographically separated populations of *K. sonoriense*, by severely limiting or even eliminating annual recruitment. Further, with the expanding range of *L. catesbeianus* in the American Southwest, it is likely that we will continue to see these effects, unless steps are taken at landscape scales to address this issue.

We greatly appreciate field assistance from P. Klink, B. Stewart and R. J. Timmons. Our fieldwork adhered to guidelines outlined in Beaupre et al. (2004. Guidelines for Use of Live Amphibians and Reptiles in Field and Laboratory Research, 2nd ed. Herpetological Animal Care and Use Committee, American Society of Ichthyologists and Herpetologists).

MACROCHELYS TEMMINCKII (Alligator Snapping Turtle). **AERIAL BASKING AND CLIMBING ABILITY**. *Macrochelys temminckii* is the largest freshwater turtle in North America (Ernst and Lovich 2009. Turtles of the United States and Canada. Smithsonian Institute Press, Washington D.C. 827 pp.), but they are seldom encountered due to their secretive nature. There are previous reports for aerial basking of *M. temminckii* hatchlings (Shelby and Jenson 2002. Herpetol. Rev. 33:304), juveniles/subadults (Ewert 1976. Herpetologica 32:150–156; Farr et al. 2005. Herpetol. Rev. 36:168; Thomas 2009. Herpetol. Rev. 40:336), and adults (Selman et al. 2008. Herpetol. Rev. 40:79). Here we report another rare aerial basking observation of a juvenile *M. temminckii*.

On 24 August 2009 (1300 h), while floating a popular recreational canoeing stretch of Black Creek (near Brooklyn, Forrest County, Mississippi, USA), we observed a juvenile *M. temminckii* (approx. 10 cm SCL) basking on a tangled root snag in the middle of the creek channel (approx. 20 m wide). The water was approximately 1.5 m deep at the site and was clear enough to see the bottom substrate (sandy gravel bottom). The tangled root snag emerged vertically out of the water approximately 50 cm and the turtle was basking near the terminus of the snag which was 5 cm in diameter at the basking site. Its head was extended completely and resting on the tip of the snag. Directly below the basking site of the turtle (approx. 15 cm from the top of the snag) was another limb (2–3 cm in diameter) that crossed perpendicular to and was touching the basking snag; from the position of the turtle, we presume it had to climb over the obstacle to get to its desired basking location. The conditions were mostly sunny (air temperature 29°C) with water discharge at 36.5 m^3/sec, well below median daily stream flow (51.8 m^3/sec; USGS Real-Time water data, Black Creek Station [station 02479130] near Brooklyn). We were unable to determine water temperatures, but at a nearby gauging station at a similar-sized creek (Tallahala Creek at Laurel, Mississippi [station 02437500]), water temperature fluctuated between 25–28°C for 24 August 2009.

The individual was initially thought to be a Razor–backed Musk turtle (*Sternotherus carinatus*) due to the similarity in basking site choice (vertical snags) and basking posture. It was only after we canoed past the individual did WS realize that it was a *M. temminckii*. Thereafter, we canoed back upstream to get a closer look and the individual dove into the water when we were within 5 m of the basking site; unfortunately, we were unable to get a photograph of the individual. Furthermore, the climbing ability of this species at this size appears to be similar to *S. carinatus* since the observed individual climbed a nearly vertical snag and maneuvered over an obstacle to get to its preferred basking site. Farr et al. (2005, *op. cit.*) also observed an individual *M. temminckii* (~35–40 cm CL) that climbed 1 m above the water and 3–4 m along a tree trunk, which also highlighted the climbing ability of this species.

Even though aerial basking is now reasonably well documented for this species, it appears to be an uncommon behavior. We suggest that future observations of this behavior should still be noted to assist in understanding the life history of this secretive turtle.

Submitted by **WILL SELMAN**, Department of Biological Sciences, Box 5018, University of Southern Mississippi, Hattiesburg, Mississippi 39401, USA (e-mail: will.selman@usm.edu); and **MARKUS WILLIG,** Moritzplatz 5, Augsburg, Germany 86150.

PSEUDEMYS NELSONI (Florida Red-bellied Turtle). **TRAUMA SURVIVAL**. Chelonians are known to be capable of surviving severe trauma (Cagle 1945. Copeia 1945:45; Landberg et. al. 2010. Herpetol. Rev. 41:70). On 15 July 2008 an adult female *P. nelsoni* was brought to Miami Metrozoo by a fisherman who collected it in Biscayne Bay near Turkey Point Nuclear Power Plant east of Homestead, Florida, USA. The turtle was missing the frontal portion of its head including both eyes. Skin had grown over the traumatized area leaving the mouth as a small, circular opening with a vestige of the tongue visible (Fig. 1). Nasal openings were not visible. Radiographs revealed that the skull had been cleanly severed over the eye sockets and the anterior portion of both lower mandibles was also missing. The turtle appeared healthy in spite of its injury and held its head up, rotating it from side to side in the same manner as a normal, sighted turtle would. The turtle weighed 2.78 kg. As it had apparently been feeding on its own since the injury, it was decided to release the animal into the semi-natural conditions of one of the zoo exhibit moats where its condition could be monitored. The moat was approximately 450 m in length (with 170 m of this dry land) by 4 m wide with water a depth of up to 1 m. Potential food available in the moat for this aquatic species included aquatic vegetation (Jackson 2006. *In* Meylan [ed.], Biology and Conservation of Florida Turtles, pp. 313–324. Chelonian Research Monographs No. 3), aquatic invertebrates, and small fish. The turtle's weight was monitored over time and increased to 3.07 kg in early October. This indicates that it was capable of ingesting food, but no observations were made

FIG. 1. Close up of *Pseudemys nelsoni* head after healing from severe trauma. Mouth opening and tongue are visible. Photo by Adam Stern.

on feeding behavior. On 9 December 2008 it was treated for a minor wound to its left foreleg. Two days later it was found dead and weighed 3.04 kg. It is surprising that this turtle was able to survive and feed with such a traumatic injury.

Submitted by **STEVE CONNERS**, Miami Metrozoo, 12400 SW 152 St., Miami, Florida 33030, USA; e-mail sconner@miamidade.gov.

STERNOTHERUS ODORATUS (Eastern Musk Turtle). **NESTING**. The nesting behavior of *Sternotherus odoratus* has apparently not been previously documented in Ohio and this species has been recorded in fewer than half of the state's 88 counties (Wynn and Moody 2006. Ohio Turtle, Lizard and Snake Atlas. Ohio Biol. Surv. Misc. Contrib. No. 10). While *S. odoratus* is known to use a variety of nest locations, we believe the site described herein to be unique, as most reports are of nests in or under rotten stumps and fallen trees (Ernst 1986. J. Herpetol. 20:341–352).

On 18 September 2009 near North Chagrin Nature Center in Cleveland Metroparks, Cuyahoga County, Ohio, USA, a hatchling *S. odoratus* was observed at the edge of a small pond. In the following days, the nest location was identified as more hatchlings were found. A total of 81 hatchlings were captured, measured, and released, with a mean (range) mass of 2.66 g (1.6–3.7 g, N = 80*)* and mean (range) carapace length of 22.75 mm (19–25 mm, N = 81*)*. The nest location was 1.5 m from the edge of the shallow 6.1-acre (2.5-ha) pond, under sandstone slab decking. The hatchlings were observed exiting from a small opening in the sandstone decking (Fig. 1) to which they were most likely drawn by the bright sunlight. It is believed that the adult females entered through an opening below the waterline (which was observed when the pond was drawn down). Under the sandstone, a hollow

FIG. 1. Aboveground view of the sandstone walk where the *Sternotherus odoratus* nest was located and crack where hatchlings were observed exiting.

cavity was discovered to be serving as a communal nest chamber (Fig. 2). It is uncertain whether the cavity was formed by erosion or possibly excavated by muskrats. This area was protected from predators and presumably provided a constant warm and humid environment for incubation. Additionally, there were older egg shells present in the cavity, indicating that nesting had occurred at this site in the past.

The sandstone decking containing the communal nest chamber was slated for demolition and renovation at the time of the emergence of the hatchlings and this allowed for exploration of the site. On 30 September 2009 the sandstone was removed and the nest site was explored for additional eggs and hatchings. Twenty-one live and four dead hatchlings were found in the substrate, and a remaining intact portion of the nest contained several unhatched eggs. These eggs were removed and placed into a plastic tub to complete incubation. From the eggs collected, 18 hatchlings emerged and were released and 5 eggs were not viable. The

FIG. 2. Underground view of *Sternotherus odoratus* nest where the concentration of eggs were deposited.

nest material consisted of a damp, coarse, sand mixture combined with soil and root material from nearby plants.

Sternotherus odoratus is a documented communal nester (Doody et al. 2009. Q. Rev. Biol. 84[3]:229–252) and in Pennsylvania Ernst (1986, *op. cit.*) reported a mean clutch size of 3.25, indicating that this nest location was the result of numerous females contributing eggs. Hatchlings that did not survive when the nest was excavated will be deposited at the Cleveland Museum of Natural History as vouchers for Cuyahoga County.

Submitted by **TIM KRYNAK** (e-mail: tjk@clevelandmetroparks.com) and **JAMES C. SPETZ** (e-mail: jimspetz@hotmail.com), Cleveland Metroparks, 3037 SOM Center Rd. Willoughby Hills, Ohio 44094, USA.

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). **SHELL ABNORMALITY**. We collected a live adult female (SCL 148 mm) *Terrapene carolina triunguis* on 1 October 2009 with a shell abnormality at the Sam Houston State University's Center for Biological Field Studies, Huntsville, Texas, USA. This specimen lacks the nuchal scute and all vertebral and pleural scutes; one abdominal scute is partially detached. There are small patches of abnormal keratinization surrounding previously healed bite wounds in the region of the third left and right pleural scutes. The absence of scutes completely exposes the carapacial bones. Although the cause of scute loss is unknown, we suspect that it is related to a past predation attempt, evidenced by the healed bite-impressions within the carapace. The carapacial bones are in good condition, and all previous damage appears superficial; there is no recent shell damage observed. Despite this shell abnormality, this individual was active and appeared otherwise healthy.

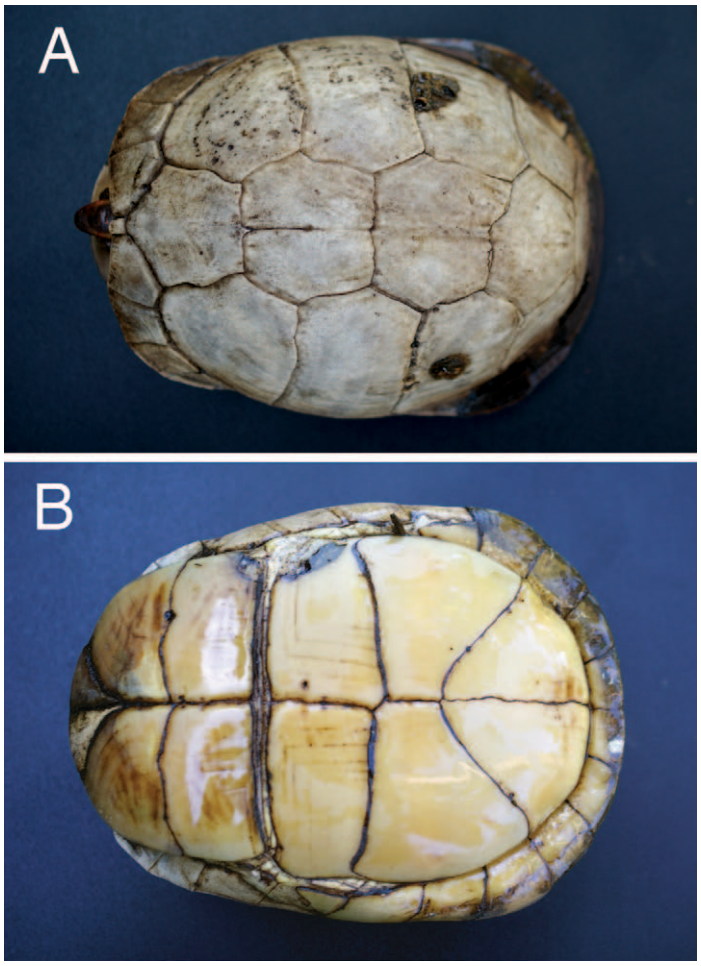

FIG. 1. *Terrapene carolina triunguis* carapace (A) and plastron (B) displaying missing and damaged scutes.

Submitted by **JEFFREY M. GOESSLING** (e-mail: goessling@shsu.edu), **JAMES C. CURETON II, TYLER M. SAXTON**, and **WILLIAM I. LUTTERSCHMIDT**, Department of Biological Sciences, Sam Houston State University, 1900 Ave. I, Huntsville, Texas 77341-2116, USA.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). **MUSKING**. Musking behavior in *Terrapene ornata ornata* has been seldom reported in wild turtles and its function is yet unknown. This behavior may serve defensive, social, or other purposes (Legler 1960. Univ. Kansas Publ., Mus. Nat. Hist. 11:527–669; Dodd 2001. North American Box Turtles: A Natural History. Univ. Oklahoma Press, Norman. 231 pp.). While conducting field research on a population of Ornate Box Turtles on the sand hills of Weld Co., Colorado, USA, we have observed 14 instances of musking during the 2007, 2008, and 2009 field seasons. We also observed musking in two captive *T. o. ornata*, one a known wild specimen originating ~25 km W of the Kansas border and one found stray within the city limits of Longmont, Colorado.

During three seasons of field research, 12 of 34 (35.3%) juveniles (SCL < 100 mm) and 2 of 48 (4.2%) adult males were observed musking. Musking turtles ranged greatly in size from yearlings (34.2 mm SCL, 10 g) to full-grown adult males (122.1 mm SCL, 397 g). Observations of two musking adult males is contrary to Neill's (1948. Copeia 1948:130) speculation in *Terrapene carolina carolina* that turtles lose the ability to musk when the plastral hinge becomes functional and Patton's observations of musking only in recently hatched juvenile *T. c. triungius (*Patton et al. 2004. Proc. Louisiana Acad. Sci. 65:22–25).

A wild adult female box turtle (SCL = 102.3 mm) collected from Cheyenne Co., Colorado was obtained in 2008 after participation in the county fair's turtle races. This turtle was housed outdoors in a naturalistic setting. On presentation of a respiratory infection during 2009, this turtle received injections of antibiotics. On three occasions, musking occurred when restraining a front leg to deliver the injection. In May 2010, the same turtle also musked during restraint. Additionally, a stray juvenile (SCL = 95.1 mm) *T. o. ornata*, found in the city limits of Longmont, Colorado in 2009, musked during gentle handling.

Turtles emitted musk as they were handled for data collection, medical treatment, and observation, presumably because of induced stress. This strong odor, distinct from urine or fecal excrement and similar to that emitted by the Common Musk Turtle (*Sternotherus odoratus*), often came in "waves" of oscillating pungency. In several turtles, we observed liquid exuded below the 4th marginal in the axillary region. The liquid was more viscous than water, taupe in color, and slightly opaque.

Submitted by **ERIC GANGLOFF** and **ANN-ELIZABETH NASH**, Colorado Box Turtle Project, 13941 Elmore Road,

Longmont, Colorado 80504, USA; e-mail: nash@corhs.org.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). **DIET AND MICROHABITAT.** *Terrapene o. ornata* is described as omnivorous, eating a broad range of animal and plant material and requiring access to water within its home range. However, within our study site standing water is generally not available and permanent water sources are well outside the typical home range areas of *T. o. ornata*. Here we provide information on one food choice, *Tradescantia occidentalis* (Prairie Spiderwort) from a wild population of Ornate Box Turtles in the sand hills of eastern Colorado that may also operate as an important water source. We also show the ready acceptance of this food item by two captive populations of wild-collected *T. o. ornata* housed in naturalistic habitats.

The present study site in Weld Co., Colorado encompasses approximately 50 ha of sand hills. The site is crossed with single-lane unpaved roads facilitating access to gas and oil wells. The property has been cattle ranched for more than 20 years; grazing is rotated with a water-pumping windmill as the focal point of each grazing section. The study area lacks any natural free-standing water and the windmill is only sporadically operated; overflow that may be used by turtles is thus unpredictable.

Average yearly precipitation at the nearest available weather station, about 16.6 km W of the study site, is 360 mm. Though more than 95% of precipitation occurs from April through October, natural ephemeral water is rarer than agriculturally related runoff. Precipitation from April though October 2009 was 32 mm greater than during the same period in 2008, and 100.6 mm greater than 2007. While 2009 precipitation was near average for the study season, the two previous years had decreased precipitation during the field study period. In 2009, *T. occidentalis* was seen during every field outing, in more areas within the study site, and in greater concentrations than in previous years.

Prairie Spiderwort is a smooth, subsucculent, perennial monocot up to 50 cm tall. Stems are often tufted, and when pulled apart, the copious mucilaginous slime inside forms what somewhat resembles a spider's web. These plants are known as "cow slobber" because of the gooey, stringy sap they produce. Given the absence of free water sources, we hypothesize that Spiderwort may be an important source of water for *T. o. ornata* in sand hills habitat. The study site also contains *Opuntia* cactus species and a variety of forbs and grasses. Ohio Spiderwort (*Tradescantia ohiensi*) has been listed as part of the floral community in *T. o. ornata* habitat in Iowa (Bowen at al. 2004. J. Herpetol. 38:562–568) and Wisconsin (Doroff and Keith 1990. Copeia 1990:387–399).

On 13 June 2008, we observed evidence of two adult turtles eating Spiderwort. The female was observed with a purple plant in her mouth, most likely *T. occidentalis* petals, and the male was observed with a chewed *T. occidentalis* stem directly in front of him and green vegetation on his beak. Several days later we located another adult female sitting in crushed Spiderwort stems with foliage stuck to her beak. During 2009, we found increased evidence of *T. o. ornata* eating Spiderwort, as well as characteristic crushed stems that may indicate turtle feeding, with three adult turtles (two females and one male) observed eating *T. occidentalis*. All observations of Spiderwort consumption occurred in the month of June.

Several specimens of *T. occidentalis* were planted into two naturalistic box turtle habitats, each more than 60 m^2. Wild-collected *T. o. ornata* readily ate this plant, often cropping it to the ground and inducing dormancy until the next growing season. This was in spite of other available food items provided on a regular basis, typically a mix of grocery-store produce (greens, vegetables, and berries). Other habitat plants including mallow (*Malva neglecta*) and common dandelion (*Taraxacum officinale*) were rarely observed being consumed. In neither captive population did we make any attempt to introduce occupants to the presence of *T. occidentalis*; turtles located and consumed this food item by free choice, often traveling 1–5 m from routine feeding locations.

CROCODYLIA — CROCODILIANS

CROCODYLUS ACUTUS (American Crocodile). **ADULT MASS**. Few data exist on the body mass of large reptiles, due in part to the difficulties of handling and weighing these animals (Minton and Minton 1973. Giant Reptiles. Charles Scribner's Sons, New York, New York. 345 pp.). In particular, few reliable data exist regarding body size of large crocodilians (Richardson et al. 2002. Crocodiles: Inside Out: A Guide to the Crocodilians and their Functional Morphology. Surrey Beatty and Sons, Ltd., Chipping Norton, NSW. 172 pp.; Webb and Manolis 1989. Crocodiles of Australia. Reed Books Pty. Ltd., Frenchs Forest, NSW. 160 pp.; Woodward et al. 1995. J. Herpetol. 29:507–513). However, crocodile research and management rely on knowledge of individual body size and size-class structure of populations (Webb and Smith 1987. *In* Webb et al. [eds.], Wildlife Management: Crocodiles and Alligators, pp. 199–210. Surrey Beatty & Sons, Ltd, Sydney) because demographic and reproductive variables are functionally dependent on body size rather than age, and population models are generally based on the former (Nichols 1987. *In* Webb et al., *op. cit*., pp. 177–187). Here, we report the body mass of a large *Crocodylus acutus* from Costa Rica.

On 13 September 2007, we captured an adult male *C. acutus* in the lower Tarcoles River, Costa Rica (9.79906389°N, 84.615278°W) during a study of ocular disease in this crocodile population. Total length (TL; anterior tip of the snout to the posterior tip of the tail, measured along the dorsal surface) and snout–vent length (SVL; anterior tip of the snout to the anterior margin of the cloacal vent, measured along the ventral surface) of the crocodile were measured with a tape as 482.6 cm and 237.5 cm, respectively. The crocodile was wrapped in an industrial cargo net and weighed using an electronic crane scale (Dynafor LLX/LLTR; Schumann GmbH, Sillerup, Germany) and manual chain hoist secured to the limb of a tree on the bank of the river. The mass of the crocodile was 537.45 kg, after subtracting the mass of the cargo net (29.54 kg).

In 2003, two of us (BRB, JRBM) captured a large *C. acutus* (TL = 395.0 cm) for translocation during a radio-tracking project in Costa Rica and determined that it weighed 500 kg (Barr 2003.

Crocodile Spec. Newsltr. 23:19). To our knowledge, these measurements of body mass are the largest yet reported for *C. acutus*, however they do not represent a maximum value for this species. *Crocodylus acutus* is known to reach lengths of 600–700 cm (Alvarez del Toro 1974. Los Crocodylia de Mexico [Estudio Comparativo]. Recursos Naturales Renovables, Mexico City. 70 pp.; Schmidt 1924. Fieldiana 12:77–96). Using an equation derived from the relationship of TL to body mass for the morphologically similar Morelet's Crocodile (*C. moreletii*) (Platt et al. 2009. Carib. J. Sci. 45:80–93), the estimated body mass of these large *C. acutus* is predicted to range from 900 to 1283 kg.

Pleasant, South Carolina 29464, USA (e-mail: thomas.rainwater@gmail.com); **LUZ DENIA BARRANTES** and **JUAN RAFAEL BOLAÑOS MONTERO**, Asociación de Especialistas en Cocodrilos - Centro América (AEC-CA), Calle 31 Avenida 10 Casa 2959, San José, Costa Rica; **STEVEN G. PLATT**, Department of Biology, Box C-64, Sul Ross State University, Alpine, Texas 79832, USA; and **BRADY R. BARR**, National Geographic Society, 1145 17th St. NW Washington, DC 20036, USA.

SQUAMATA — LIZARDS

AMEIVA FESTIVA (Central American Whiptail Lizard). **CANNIBALISM**. *Ameiva festiva* is a broadly distributed, dietary generalist that consumes diverse arthropod prey including crickets, spiders, roaches, and katydids (Vitt and Zani 1996. J. Herpetol. 30:110–117; Vitt and Zani 1998. J. Trop. Ecol. 14:537–559; Whitfield and Donnelly 2006. J. Trop. Ecol. 22:409–417). Lizards, however, have been recorded infrequently in their diet (Vitt and Zani 1998, *op. cit.*) and accounts identifying the lizard species taken are lacking. Hence, here we report an *A. festiva* preying on a conspecific in the Gandoca-Manzanillo Wildlife Refuge, Costa Rica.

At 1127 h on 21 July 2008, while walking the grounds at the Iguana Verde Foundation (09.63818°N, 82.70496°W, datum WGS84; elev. 3 m), we observed, photographed, and videotaped one adult female *A. festiva* (ca. 9 cm SVL) grasping a conspecific (ca. 4 cm SVL) by its head. The smaller lizard was alive but missing half its tail, which was seen ca. 7 cm away. The adult was biting the head of the smaller conspecific continually until a probable male (ca. 10 cm SVL) *A. festiva* approached and began undulating its tail. The adult female fled 2.5 m away and began manipulating her prey in a head-first orientation. The adult female *Ameiva* took one minute to swallow its prey, and then performed an undulating maneuver with its torso, and completed its consumption at 1134 h.

This is the first observation of cannibalism in this frequently observed species, and augments our knowledge of trophic relationships for *Ameiva* lizards and their behavioral ecology. This observation was made while conducting *Iguana iguana* research supported by the San Diego Zoo's Institute for Conservation Research.

KNAPP**, San Diego Zoo's Institute for Conservation Research., Zoological Society of San Diego, 15600 San Pasqual Valley Road, Escondido, California 92027, USA (e-mail: cknapp@ufl.edu).

APHANIOTIS ACUTIROSTRIS (Indonesia Earless Agama). **REPRODUCTION.** *Aphaniotis acutirostris* is known from Indonesia (Uetz and Hallermann 2010. The Reptile Database http://www.reptile-database.org, accessed 22 July 2010). To my knowledge, the only information on *A. acutirostris* is a report of clutch sizes of two eggs deposited every 30–100 days and hatching 48–63 days later (Das 2006. A Photographic Guide to Snakes & Other Reptiles of Borneo. Ralph Curtis Publishing, Sanibal Island, Florida. 144 pp.). The purpose of this note is to provide additional information on the reproductive biology of *A. acutirostris.*

A sample of 18 *A. acutirostris* (nine males, mean SVL = 53.4 mm ± 2.2 SD, range = 51–56 mm; four females, mean SVL = 50.3 mm ± 2.1 SD, range = 48–53 mm; four subadults, mean SVL = 31.0 mm ± 4.8 SD, range = 28–38 mm; and one neonate, SVL = 23 mm, collected July 1975 at Bohorok, North Sumatra, Indonesia (3.516667°N, 98.133333°E; WGS84, 255–1390 m elev.) was examined from the herpetology collection of the Field Museum of Natural History (FMNH): FMNH 209533, 209534, 209536–209539, 209541–209545, 209552–209554, 209556, 209557, 209559, 209564. For histological examination, the left gonad was removed to check for yolk deposition in females and spermiogenesis (sperm formation) in males. Counts were made of enlarged ovarian follicles (> 4 mm length) or oviductal eggs. Tissues were embedded in paraffin and stained with hematoxylin followed by eosin counterstain. Histology slides are deposited in FMNH.

All males examined were undergoing spermiogenesis; the lumina of the seminiferous tubules were lined by clusters of sperm or groups of metamorphosing spermatids. The smallest reproductively active male measured 51 mm SVL. One female contained two vitellogenic follicles (2 mm length); two females each contained two enlarged ovarian follicles (4 mm diameter) and one female contained two oviductal eggs. The smallest reproductively active female (oviductal eggs) measured 48 mm SVL. The presence of the neonate (23 mm SVL), plus three slightly larger juveniles (28, 28, 30 mm SVL) indicates they were born earlier in the year and that *A. acutirostris* has a prolonged period of reproduction. Inger and Greenberg (1966. Ecology 47:1007–1021) reported continuous reproduction in five agamid species (*Draco melanopogon*, *D. obscurus*, *D. quinquefasciatus*, *Gonocephalus grandis*, *G. liogaster*) from a Bornean rain forest. Whether *A. acutirostris* breeds throughout the year will require examination of additional monthly samples.

I thank Alan Resetar (FMNH) for permission to examine *A. acutirostris.*

ASPIDOSCELIS TIGRIS (Western Whiptail) **DIET.** *Aspidoscelis tigris* is a common lizard of North American arid lands. Active forager, whiptails generally forage on the ground, often near veg-

etation, where they dig in leaf litter or probe cracks and crevices in search of prey (Pianka 1970. Ecology 51:703–720). Whiptails feed primarily on diverse ground-dwelling arthropods (Best and Gennaro 1985. Great Basin Nat. 45:527–534), but are not recorded to take honey bee (*Apis mellifera*) prey. Here, I present the first record of *A. tigris* attacking and consuming a honey bee.

At 1200 h on 29 July 2002, I observed three adult *A. tigris* foraging beneath a stand of saltcedar (*Tamarix* sp.) in a dry wash in the northwest portion of the Glen Canyon National Recreation Area, Garfield Co., Utah, USA (37.642614°N, 111.067225°W, datum WGS84; elev. 1510 m). The lizards seemed unaware of my presence as they foraged in the leaf litter. The saltcedar was in full flower, and many bee species were visiting the flowers. A honey bee flew down from a low-lying flower, landing on the ground ca. 1 m from one of the *A. tigris*. The lizard immediately ran over to the bee, caught it, and began chewing it rapidly. As the *A. tigris* began ingesting the bee, it rubbed its snout on the ground several times. It is unknown whether it was trying to avoid being stung or if the hairy body of the bee was irritating the inside of its mouth. Other whiptails have been reported to rub their snout on the ground when attacking hairy arthropods, like some caterpillars (Burt 1928. J. Kansas Ent. Soc. 1:50–68). The entire attack and ingestion episode lasted <1 min. I continued to watch the lizards forage under the saltcedar for ca. 15 min, and the *A. tigris* that had ingested the bee behaved normally, showing no adverse effects from the encounter.

This record merits comment given the potentially toxic nature of this insect. Feeding experiments have revealed that the Eastern Fence Lizard (*Sceloporus undulatus*) always refused honey bees when offered them, and in one instance, a lizard was stung by a bee and died minutes later (Burt 1928. J. Kansas Entomol. Soc. 1:50–68). Whether the *A. tigris* individual was stung by the bee in this instance is unknown, but the fact that the lizard was able to attack and eat the bee without harmful consequence is noteworthy.

Submitted by **JOSEPH S. WILSON,** Utah State University, Biology Department, 5305 Old Main Hill, Logan, Utah 84322, USA; e-mail: jwilson@biology.usu.edu.

GONATODES HUMERALIS (Trinidad Gecko). **ENDOPARASITES.** *Gonatodes humeralis* is widespread in northern South America and occurs in French Guiana, Suriname, Ecuador, Guyana, Peru, Bolivia, NE Venezuela, Colombia, Brazil, as well as Trinidad and Tobago (Uetz and Hallermann 2010. http.reptile-database.org, accessed 20 May 2010). The purpose of this note is to add to the helminth list of *G. humeralis.*

Fifteen *G. humeralis* (mean SVL = 36.9 mm ± 2.0 SD, range = 34–40 mm) collected from 1905 to 1973 from Peru, Loreto Department, Moropon (3.748056°S, 73.246933°W; WGS84; 107 m elev.) and deposited in the Texas Cooperative Wildlife Collection (TCWC), Texas A & M University, were examined for helminths (TCWC 36674, 36684, 36737, 36739, 38996, 41173, 41226, 41761, 41801, 41910, 41911, 41920, 41922, 42714, 42715).

The body cavities were opened and the digestive tracts removed. Contents were examined under a dissecting microscope. Digeneans were regressively stained in hematoxylin and mounted on glass slides in Canada balsam. Nematodes were cleared on glass slides in glycerol. All were cover-slipped, studied under a compound microscope and identified. Found were one species of Digenea, *Mesocoelium monas* (N = 173, small intestine, prevalence = number infected lizards/number lizards examined x 100 = 7%; mean intensity, mean number helminths per infected lizard ± 1 SD = 173) and three species of Nematoda, *Parapharyngodon scleratus* (large intestine, N = 2, prevalence = 7%, mean intensity = 2), *Physaloptera retusa* (stomach, N = 6, prevalence = 20%, mean intensity = 2.0 ± 1.0, range = 1–3), *Skrjabinelazia galliardi* (small intestine, N = 2, large intestine, N = 2, prevalence = 20%, mean intensity = 1.3 ± 0.6, range = 1–2). Voucher helminths were deposited in the United States National Parasite Collection, USNPC, Beltsville, Maryland: *Mesocoelium monas* (103203); *Parapharyngodon scleratus* (103204); *Physaloptera retusa* (103205); *Skrjabinelazia galliardi* (103206).

Mesocoelium monas is cosmopolitan in distribution and has been recorded from fishes, amphibians, and reptiles from the New and Old Worlds (Goldberg et al. 2009. Comp. Parasitol. 76:58–83). *Parapharyngodon scleratus* has been reported in a variety of lizards from Brazil and also occurs in Peru (Bursey et al. 2005. Comp. Parasitol.72:50–68). *Physaloptera retusa* is widely distributed in lizards and a few amphibians in the western hemisphere and has been reported from Mexico, North and South America, and the West Indies (Bursey et al. 2007, *op. cit.). Skrjabinelazia galliardi* was originally described from *G. humeralis* collected in Brazil (Chabaud 1973. Ann. Parasitol. Hum. Comp. 48:329–334). *Gonatodes humeralis* represents a new host record for *Mesocoelium monas, Parapharyngodon scleratus*, and *Physaloptera retusa*. Peru is a new locality record for *Skrjabinelazia galliardi*

We thank Lee Fitzgerald and Toby Hibbitts (TCWC) for permission to examine specimens and Daisy Salguero (Whittier College) for assistance with dissections.

HELODERMA SUSPECTUM (Gila Monster). **TREE-CLIMBING**. *Heloderma suspectum* occupies a variety of terrestrial habitats in all deserts of the United States and northern mainland Mexico (Beck 2005. Biology of Gila Monsters and Beaded Lizards. University of California Press, Berkeley and Los Angeles. 247 pp.; Campbell and Lamar 2004. Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York. 870 pp.). Despite the fact these regions substantially differ with respect to environmental factors and habitats (Brown 1994. Biotic Communities of the American Southwest—United States and Mexico. University of Utah Press, Salt Lake City. 342 pp.), *H. suspectum* selects similar types of microhabitats and shelters (Beck 2005, *op. cit*.; Beck and Jennings 2003. Herpetol. Monogr. 17:111–129), which are commonly bushes and structures with subterranean components (e.g., rock formations and small mammal burrows). Rarely, *H. suspectum* exhibits arboreal activities, particularly with regard to tree climbing (Beck 2005, *op. cit*.;

Cross and Rand 1979. Southwest. Nat. 24:703–705).

Here, we provide additional information on tree climbing of an adult *H. suspectum* from a population in the Sonoran Desert of south-central Arizona. The individual we discuss herein is the subject of an ongoing radio-telemetric study in which various features of behavior, physiology, and spatial ecology have been investigated since March 2001 (Kwiatkowski et al. 2008. J. Zool. 276:350–357; Repp and Schuett 2009. Herpetol. Rev. 40:343–345).

The present study site, located in Pinal Co., is 40 km SSE of the city of Florence, 8 km W of State Route 79, and encompasses an area of ~3 km^2 at the extreme western edge of the Suizo Mountains (Iron Mine Hill). The region is ecologically designated as Arizona Upland Desertscrub subdivision (Brown 1994, *op. cit.*).

On 25 April 2010, at 1205 h, in an area interfacing bajada (Phillips and Comus 2000, *op. cit.*) and desert flats, an adult male *H. suspectum* (HS-15: SVL = 291 mm; TL = 133 mm; tail volume = 49 ml; body mass = 470 g) was radio-tracked and located (site 5, elev. 826 m) beneath a moderate-sized (4 m H x 4 m W) Yellow Paloverde (*Cercidium microphyllum*; Fig. 1). The dominant vegetation directly beneath the tree was a dense stand of Fiddleneck (*Amsinckia intermedia*) with limited Triangle Bursage (*Ambrosia deltoidea*). Additional vegetation nearby included Engelmann's Prickly Pear (*Opuntia engelmannii*) and Buckhorn Cholla (*Opuntia acanthocarpa*). HS-15 was originally collected and processed on 12 March 2010, and has been radio-tracked on a weekly basis. Upon detection on 25 April, HS-15 began a deliberate (non-erratic) and consistent ascent into the tree that continued for about 1 min; he stopped and remained on a large (35 mm circumference) main branch angled at 20–35º and approximately 1.2 m above the ground (Fig. 1). He was outstretched facing eastward, in diffuse sunlight, and remained in that position, sometimes with his eyes closed, until we left (1230 h). Cross and Rand (1979, *op. cit.*) observed two adult *H. suspectum* ascended into Desert Willows (*Chilopsis linearis*) at similar heights (90 cm and 2.5 m) and attained similar postures on branches, as we report herein. However, they did not report dates and times of day, other than morning and evening.

The core body temperature of HS-15 (obtained via an implanted 9.0 g temperature-sensitive radio transmitter; Holohil Systems Ltd., Ontario, Canada) while he was at his final location in the tree was 32.3ºC. Ambient temperature (1 m above the ground in shade) was 28.0ºC; ground temperature in direct sunlight beneath the tree was 51ºC. Cloud cover was 0%, relative humidity was < 10%, and wind speed was slight (0–8 kph) and intermittent.

We are unable to determine whether HS-15 made his ascent to escape our presence or for other reasons, such as avoiding high ground temperatures. Support for the latter view is that we were unable to locate burrows, woodrat (*Neotoma albigula*) middens, or any other shelters often used by *H. suspectum* (see Beck and Jennings 2003, *op. cit.*). Moreover, in a nearby (4 km S) population, Davis and DeNardo (2010. J. Herpetol. 44:83–93) determined the mean activity body temperature of *H. suspectum* to be 26.4 (± 0.83°C), which indicates that the core body temperature of 32.3°C present in HS-15 was approaching the voluntary maximum of 35–37°C (D. Beck and D. DeNardo, pers. comm.). The critical thermal maximum for *H. suspectum* is believed to be ~44°C (Beck 2005, *op. cit.*).

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Tree climbing by an adult male, wild-living Gila Monster, *Heloderma suspectum*. This individual (HS-15) is shown at his final location in a Yellow Paloverde (*Cercidium microphyllum*). Photograph by R. A. Repp.

We did not locate bird nests in the tree used by HS-15; thus, it appears unlikely that foraging was a motivation to climb. Unlike Beaded Lizards (*H. horridum* sensu lato; see Douglas et al. 2009. Mol. Phylogenet. Evol. 55:153–167), which often forage in trees (Beck 2005, *op. cit.*), *H. suspectum* predates mostly on ground-nesting avian and mammalian species (Beck 2005, *op. cit.*; Repp and Schuett 2009, *op. cit.*). To date, there are no observations to support arboreal foraging in *H. suspectum*.

Our field studies at Suizo Mountain have been funded by Arizona State University, Zoo Atlanta, Georgia State University, and Dr. David L. Hardy, Sr. Since 2001, many individuals provided assistance in radio-tracking, but most noteworthy are Hans-Werner Herrmann and Ryan Sawby. Also, Ryan Sawby provided invaluable assistance with photography and identification of plants and invertebrates. We thank Dan Beck, Dale DeNardo, Matt Goode, Jim Jarchow, and Brian Sullivan for various favors. This study was approved by the IACUC of Arizona State University (98-429R), and appropriate scientific permits were obtained from the Arizona Game and Fish Department.

Submitted by **ROGER A. REPP**, National Optical Astronomy Observatory, 950 North Cherry Avenue, Tucson, Arizona 85719, USA (e-mail: repp@noao.edu); and **GORDON W. SCHUETT**, Department of Biology and Center for Behavioral Neuroscience, Georgia State University, 33 Gilmer Street, Unit 8, Atlanta, Georgia 30303-3088, USA (e-mail: biogws@langate.gsu.edu, or gwschuett@yahoo.com).

HEMIDACTYLUS MABOUIA (Tropical House Gecko). **PREDATION.** *Hemidactylus mabouia* is a broadly distributed species in the tropics and has been introduced to the New World, with populations having successfully colonized southern areas of North America and Central and South America (Federico and Cacivio 2000. Herpetol. Rev. 31:53). The Roadside Hawk (*Buteo magnirostris*) is a medium-sized hawk that often is associated with thinned forests, forest edges, and natural or anthropogenic clearings (Bierregaard 1994. *In* Hoyo [org.], Handbook of the Birds of the World, Vol. 2, p. 179). Its diet can contain a variety

of organisms including large invertebrates and small vertebrates (Haverschimidt 1962. Condor 64:154–158; Panasci et al. 2002. Wilson Bull. 114:114–121). This note reports an observation of predation on *H. mabouia* by *B. magnirostris*.

At 1654 h on 2 November 2009, in the Central Campus of Universidade Federal do Rio Grande do Norte (UFRN), municipality of Natal, State of Rio Grande do Norte, Brazil (256117.385°E, 9354212.344°N; datum WGS84), elev. 34.5 m, BRMM observed a Roadside Hawk on a tree branch within remnant forest with a *H. mabouia* in its bill. The lizard was not moving, indicating it was no longer alive. BRMM observed the hawk closely, using binoculars (SUMAX 12-45x70 BS Ventura), to make a positive identification of the gecko. The hawk flew away with the prey item.

Submitted by **BRUNO RAFAEL MORAIS DE MACÊDO** (e-mail: brunormm@gmail.com), and **ELIZA MARIA XAVIER FREIRE** (e-mail: elizajuju@ufrnet.br), Laboratório de Herpetologia, Departamento de Botânica, Ecologia e Zoologia, Centro de Biociências, Universidade Federal do Rio Grande do Norte, Campus Universitário Lagoa Nova, CEP 59072-970, Natal, Rio Grande do Norte, Brazil.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). **HERMAPHRODITISM.** Many sexual anomalies have been reported in lizards including hermaphroditism caused by radiation exposure in *Lacerta vivipara* (Semenov and Ivanova 1995. Russ. J. Herpetol. 2:166–169), sexual development anomalies caused by varying incubation temperatures in *Lacerta viridis* (Raynaud and Pieau 1985. *In* C. Gans and F. Billet [eds.], Biology of the Reptilia, Vol. 15, Development B, pp. 149–300. John Wiley and Sons, New York), and development of hemipenes in female Leopard Geckos (*Eublepharis macularius*; Holmes et al. 2005. Horm. Behav. 47:439–445). However, few reports of hermaphrodite lizards from wild populations exist (but see Darevsky et al. 1978. Copeia 1978:201–207; Goldberg 1989. Copeia 1989:486–488). As part of a study of the accumulation of potential pollutants in the tissues of Mediterranean Geckos (*Hemidactylus turcicus*; Kinney et al. 2008. Herpetol. Conserv. Biol. 3:247–253), we histologically examined the gonadal tissues of specimens collected from buildings at several sites in southwestern Louisiana, USA. This study discovered a hermaphroditic Mediterranean Gecko which we describe herein.

Collections of geckos were made between June and August 2006, representing the middle of the gecko reproductive season in Louisiana, to ensure that the gonadal tissue was well developed (i.e., males would have sperm cells and females would have developing eggs). Sex of adults (SVL > 42 mm; Selcer 1986. Copeia 1986:956–962) was initially determined in the field: males were identified by the presence of pre-anal pores in a chevron pattern. Specimens were sacrificed by pithing; testes and epididimides were dissected from the males, ovaries (including eggs) were dissected from the females, and all tissues were placed in 10% neutral buffered formalin. Tissues were dehydrated in alcohol, cleared in xylene and paraffin embedded. Seven-micron-thick sections were made and slides stained with hematoxylin and eosin. Six adult male and seven adult female specimens collected from five sites in Beauregard and Calcasieu parishes, Louisiana were examined.

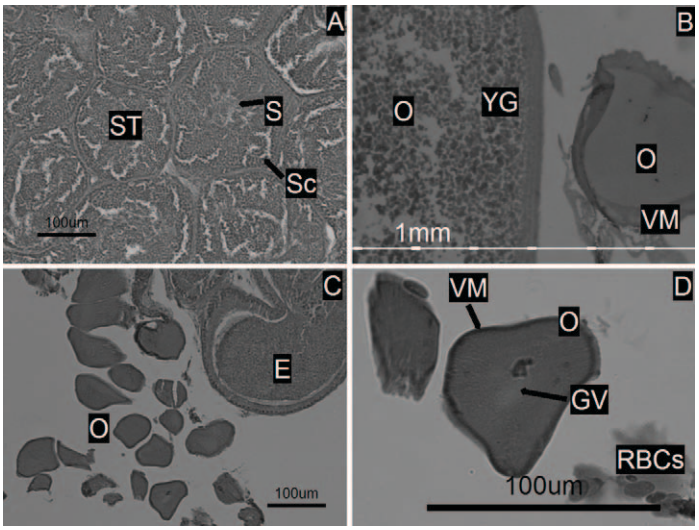

Fig. 1. **A**. Normal male *Hemidactylus turcicus*: testis with seminiferous tubules filled with all stages of germ cells. **B.** Normal female *Hemidactylus turcicus*: oocytes at various stages of development. **C.** Hermaphrodite *Hemidactylus turcicus*. Note oocytes associated with epididymis. **D.** Close-up of oocytes of hermaphrodite *Hemidactylus turcicus*. ST = seminiferous tubule; S = spermatozoa; Sc = spermatocytes; O = oocytes; YG = yolk granules; VM = vitelline membrane; E = epididymis; GV = germinal vesicle; RBCs = red blood cells.

A specimen initially identified as a male collected 13 June 2006 from the clubhouse at Lake Charles Country Club in Calcasieu Parish was found to have both testicular/epididymal and ovarian tissue (Fig. 1). The testicular tissue appeared normal and all stages of sperm development were present (including mature sperm in the epididymis, Fig 1C). The ovarian tissue was separate from the testes and appeared intimate with the epididymis (Fig. 1C). The oocytes were all immature (stage one development indicated by lack of perinucleoli or yolk development). The germinal vesicle (nucleus), as well as the vitelline membrane surrounding the eggs can also be seen (Fig. 1D). Because this individual possesses both male and female gonadal tissues, it is a true hermaphrodite (or intersex). To our knowledge, this is the first report of a hermaphroditic Mediterranean Gecko captured from a wild population.

This study was carried out in accordance with the McNeese State University Institutional Animal Care and Use Regulations. Specimens were collected under the authority of Louisiana Department of Wildlife and Fisheries Scientific Collecting Permit LNHP-06-052.

PAULISSEN,** Department of Natural Sciences, Northeastern State University, Tahlequah, Oklahoma 74464, USA (e-mail: paulisse@nsuok.edu).

IGUANA IGUANA (Green Iguana). **NESTING**. In Central America, female *Iguana iguana* deposit large clutches of eggs from February through April (Stafford and Meyers 2000. A Guide to Reptiles of Belize. Academic Press, New York. 356 pp.). Eggs are laid in burrows, which females often construct in sandbanks

along creeks and rivers (Stafford and Meyers, *op. cit.*). In Panama, female *I. iguana* reportedly construct nesting burrows in close proximity to American Crocodile (*Crocodylus acutus*) nests (Rand 1968. Copeia 1968:552–561; Dugan et al. 1981. J. Herpetol. 15:409–414). Here we report observations of *I. iguana* using crocodile nests as oviposition sites in southern Belize. Crocodile embryos obtained from these nests, through genetic analysis, were determined to be *C. moreletii* × *acutus* hybrids (Hekkala 2004. Conservation Genetics at the Species Boundary: Case Studies from African and Caribbean Crocodiles [Genus: Crocodylus]. PhD dissertation, Columbia University, New York. 92 pp.).

On 20 April 1997, we found two crocodile nests 240 cm apart on a sandbar along Paynes Creek, Paynes Creek National Park, Toledo District (16.35830°N, 88.56604°W, datum WGS84; elev. ca. 10 m). Each crocodile nest consisted of a sand mound ca. 140 cm wide × 90 cm high. One nest contained 25 *I. iguana* eggs, but no crocodile eggs, and the other contained one *I. iguana* egg and 42 crocodile eggs. In the latter nest, the *I. iguana* egg was buried beneath the crocodile eggs. Remains of at least five more *I. iguana* eggs were scattered around the second nest, implying that the female crocodile had unearthed them during oviposition. The extent of banding visible on the crocodile eggs (Platt et al. 2008. J. Zool. 275:177–189) indicated the clutch was deposited about five days earlier. Because crocodile nests are generally constructed 5–7 days prior to egg laying (Platt et al., *op. cit.*), the *I. iguana* clutches were likely deposited in early April. On 15 May 1997, we found two additional crocodile nests on sandbars along the Swasey Branch of Monkey River, Toledo District. The first nest (16.41888°N, 88.53466°W, datum WGS84; elev. ca. 15 m), a large sand mound measuring approximately 300 cm wide × 100 cm high, contained 38 crocodile eggs and 17 *I. iguana* eggs; the latter were buried about 5 cm beneath the crocodile eggs. We estimated the crocodile eggs to be about three weeks old. Hence, the *I. iguana* eggs were likely deposited in mid-April. A second crocodile nest (16.42833°N, 88.54361°W, datum WGS84; elev. ca. 32 m) found on a sandbar downstream from the previous nest contained 23 crocodile eggs, but no *I. iguana* eggs. However, abundant tracks and excavations indicated *I. iguana* were nesting on the sandbar adjacent to the crocodile nest.

Given an incubation period of ca. 90 days (Hirth 1963. Ecology 44:613–615; Rand 1972. Herpetologica 28:252–253), *I. iguana* eggs deposited early-to-mid April are expected to hatch early-to-mid July, a period coinciding with the onset of the wet season (Platt et al., *op. cit.*). In Belize, *Crocodylus acutus* eggs hatch after an incubation period of 78–81 days, and hatchlings emerge from the nest during the same period as *I. iguana* (Platt and Thorbjarnarson 2000. Copeia 2000:869–873). *Crocodylus moreletii* has a similar incubation period (ca. 75 days), though clutches are not deposited until after the wet season commences in late June and July (Platt et al., *op. cit.*). Although the incubation period of *C. moreletii* × *acutus* hybrids has yet to be determined, it is expected to be similar to both parental species. Thus, hatchling *I. iguana* and hatchling crocodiles probably emerge from the nest at about the same time. To our knowledge, these are the only reports outside of Panama of *I. iguana* depositing eggs in crocodile nests. Presumably, fitness advantages in the form of increased nest and hatchling survival accrue to female *I. iguana* from the nest defense behavior of female crocodiles (Dugan et al., *op. cit.*). However, female crocodiles occasionally unearth *I. iguana* eggs when excavating nests, and female *I. iguana* also risk being captured and consumed by female crocodiles defending nests (Dugan et al., *op. cit.*).

We thank Eloy Quevas for bringing the crocodile nests to our attention, Travis Crabtree, Steve Lawson, and Lewis Medlock for field assistance, and Bruce Cullerton and Rainforest Mechanics, Inc. for transport. Jacob and Kelly Marlin and the Belize Foundation for Research and Environmental Education provided logistical support. Richard Montanucci and Chris Pipes provided useful references and assistance.

MABUYA ARAJARA (NCN). **DEATH-FEIGNING.** Death-feigning (thanatosis) is a state of immobility in response to external stimuli that has been considered a defense mechanism against predators shared by various animals, including snakes and lizards (Gehlbach 1970. Herpetologica 24–34; Rocha 1993. Cienc. Cult. 45:116–122). This defensive behavior been observed in several different families of lizards, including Dibamidae (Torres-Cervantes et al. 2004. Herpetol. Rev. 35:384), Crotaphytidae (Gluesing 1983. Copeia 1983:835–837), Tropiduridae (Bertoluci et al. 2006. Herpetol. Rev. 37:472–473; Galdino and Pereira 2002. Herpetol. Rev. 33:54; Gomes et al. 2004; Kohlsdorf et al. 2004. Herpetol. Rev. 35:390–391), but has been less documented in Scincidae (Langkilde et al. 2003. Herpetol. J. 13:141–148). *Mabuya arajara* is a skink found only in high elevation areas of northeastern Brazil (Joventino and Loebmann 2010. Herpetol. Bull. 113:4–10; Rebouças-Spieker 1981. Pap. Avul. Zool. 34:121–123; Ribeiro et al. 2008. Cad. Cult. Ciênc. 1:67–76). Little information exists on the natural history of *M. arajara*. Here, we report thanatosis in *M. arajara* during a collecting expedition in Araripe Mountain Plateau, municipalities of Barbalha (07.3186111°N, 39.4011111°W, WGS84) and Crato (07.2552778°N, 39.4680556°W, WGS84), Ceará. Three specimens were hand captured between 1500–1600 h on 11–12 May 2010. Every time the skinks were handled, they promptly exhibited death feigning, although their eyes remained open; these behaviors lasted for about 3 min, even after being placed on the ground. Among lizard species, thanatosis is a behavior rarely observed in natural situations (Greene 1988. *In* Gans and Huey [eds.], Biology of the Reptilia, Vol. 16, Ecology and Defense, pp. 1–52. Alan R. Liss. Inc., New York) but handling may induce this behavior in many lizard species (Rocha 1993, *op. cit.*). Thanatosis in *M. arajara* may cause predators to lose interest in the potential prey and give them an additional opportunity to escape. The three skink specimens were deposited in the zoological collection of the Universidade Regional do Cariri/LZ-URCA, Ceará,

Brazil as LZ-URCA 779, 780, and 783. We thank CAPES (Coordenação de Aperfeiçoamento de Pessoal de Nível Superior) for the scholarship to SCR. We are also grateful to IBAMA (Brazilian Institute for the Environment and Natural Resources) for permission to collect samples from protected areas (permit 154/2007 and process 20388-1)

OPHISOPS ELEGANS (Snake-eyed Lizard). **ENDOPARASITES.** *Ophisops elegans* is a widely distributed lacertid in the Middle East occurring from the Bosphorus through Iran, south to the Sinai Peninsula and Red Sea Coast of Egypt, Jordan, Iraq, and the Transcaucasian republics where it is commonly found on stony plains and hillsides (Anderson 1999. The Lizards of Iran. SSAR Contrib. Herpetol. 15:1–442). We know of no published accounts of helminths from this lizard. The purpose of this note is to establish the initial helminth list for *O. elegans*.

Six *O. elegans* (mean SVL = 45.0 ± 3.3 SD, range = 42–49 mm) from The Islamic Republic of Iran, Khuzestan Province, Shalgahi (32.416667°N, 48.866667°E, WGS84, elev. 12 m) were examined for helminths from the herpetology collection of the Museum of Comparative Zoology (MCZ), Harvard University: (MCZ R-56694, 56695, 56697, 56699, 56705, 56737).

The body cavity was opened and the digestive tract was removed and examined under a dissecting microscope for helminths. Seven cestodes were found in the small intestines of four *O. elegans* (prevalence, number infected lizards/number examined lizards × 100 = 67%; mean intensity, average number helminths per infected lizard = 1.8 ± 0.96 SD, range: 1–3). Cestodes were regressively stained in hematoxylin and identified under a compound microscope as *Oochoristica tuberculata.* They were deposited in the invertebrate collection at MCZ as IZ-95760–95763.

Oochoristica tuberculata is widely distributed in the Old World and occurs in a variety of lizards and some snakes; distribution and hosts are summarized in Yildirimhan et al. (2006. Comp. Parasitol. 73:257–262). Although the life cycle of *O. tuberculata* is unknown, the congener *O. anolis* utilizes beetles as intermediate hosts (Conn 1985. J. Parasitol. 71:10–16). *Ophisops elegans* represents a new host record for *Oochoristica tuberculata*. The Islamic Republic of Iran is a new locality record.

We thank Jonathan B. Losos and Jose Rosado (MCZ) for permission to examine *O. elegans* and Cecilia Nava (Whittier College) for assistance with dissections.

BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

POTAMITES JURUAZENSIS (NCN). **ENDOPARASITES.** *Potamites juruazensis* (Gymnopthalmidae) is known from Acre Province, Brazil (Avila-Pires and Vitt 1998. Herpetologica 54:235–2450) and Peru (Doan and Castoe 2005. Zool. J. Linn. Soc. 143:405–416). There are, to our knowledge, no reports of helminths from *P. juruazensis*. In this report we establish an initial helminth list for *P. juruazensis*.

Twenty *P. juruazensis* (9 females, 11 males), mean SVL = 40.3 mm ± 11.1 SD, range = 24–58 mm) from ca. 5 km N of Porto Walter (8.25861°S, 72.77694°W; WGS 84; elev. 198 m) Acre State, Brazil collected by LJV and Teresa C. Ávila-Pires and deposited in the Sam Noble Oklahoma Museum of Natural History, Norman, Oklahoma as OMNH 36861–36880 were examined for endoparasites.

The body cavity was opened and the intestines removed and examined under a dissecting microscope. Because these specimens had previously been used in an ecological study (Vitt and Avila-Pires 1998. Copeia 1998:570–582), the stomachs were not available for examination. Ten nematodes were found in the small (N = 5) and large intestines (N = 5). They were cleared in glycerol on a microscope slide, studied under a compound microscope and identified as *Cosmocerca vrcibradici*, prevalence = number infected individuals/number individuals examined × 100 = 30%; mean intensity mean number parasites per infected lizard = 1.67 ± 0.52 SD, range = 1–2. Voucher specimens were deposited in the United States National Parasite Collection, Beltsville, Maryland as USNPC 103198.

Cosmocerca vrcibradici was described from the gymnophthalmids *Prionodactylus eigenmanni* and *P. oshaughnessyi* from Brazil and Ecuador (Bursey and Goldberg 2004. J. Parasitol. 90:140–145) and has subsequently been reported from *Uranoscodon superciliosus* from Brazil (Bursey et al. 2005. J. Parasitol. 91:1395–1398), *Norops fuscoauratus* from Brazil (Goldberg et al. 2006. Phyllomedusa 5:83–86), *Alopoglossus angulatus* and *A. atriventris* from Brazil and Ecuador (Goldberg et al. 2007. Herpetol. J. 17:269–272), and *Arthrosaura reticulata* from Ecuador (Goldberg et al. 2010. Herpetol. Rev. 41:349–350). The report of *C. vrcibradici* in *Chalcides ocellatus* from Egypt by Ibrahim and Soliman 2005 (Parasite 12:317–323) requires verification. *Potamites juruazensis* represents a new host record for *Cosmocerca vrcibradici.*

We thank Cecilia Nava (Whittier College) for assistance with dissections.

SCELOPORUS MINOR (Minor Lizard). **PREDATION.** *Sceloporus minor* is a colorful phrynosomatid restricted to saxicolous habitats in central México (Wiens et al. 1999. Evolution 53:1884–1897). To date, there are few published reports on the ecology of this species (Ramírez-Bautista et al. 2008. Herpetol. J. 18:121–127) and to our knowledge, nothing regarding predation. Between 2005 and 2008 we studied a population of *S. minor* in the Los Mármoles region of NW Hidalgo state (Stephenson 2010. Unpubl. Ph.D. dissertation, University of Miami, Coral Gables, Florida. 187 pp.) near the community of La Manzana (20.87°N, 99.22°W, WGS84; elev. 2400 m). Here, mixed oak-pine forest (primarily *Quercus crassipes* and *Pinus greggii*) is interrupted by sharp limestone outcroppings. These rocky outcrops represent the primary habitat for *S. minor* in this area, and both adults and juveniles are commonly observed basking and displaying on boulders and rock piles (Stephenson 2010, *op. cit*.). In the southern part of its range *S. minor* is sympatric with the Querétaro Dusky Rattlesnake, *Crotalus aquilus* (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York). Near La Manzana, adult *C. aquilus* are active during the day (Armstrong and Murphy 1979. Spec. Publ. Mus. Nat. Hist. Univ. Kans. [5]:1–88), and commonly observed on and around exposed boulders used by *S. minor* (Stephenson 2010, *op. cit*.). In this report we describe two observations of predation on *S. minor* by *C. aquilus*, representing the first descriptions of predation on *S. minor* by any species and extending knowledge pertaining to the diet of *C. aquilus*.

On 12 August 2006 three of us (BPS, ELMV, and NI) observed and followed an adult *C. aquilus* tracking and ultimately consuming a previously marked subadult female *S. minor* (measured 47.7 mm SVL on 28 July 2006). The lizard was found on a small dirt trail in a hillside dominated by low-growing (<1 m) shrubby vegetation. Because this encounter was lengthy (almost 3 h), we provide a detailed summary:

- 1144 h: Lizard found motionless on ground in normal upright posture; *C. aquilus* located ~10 cm away (air temperature at breast height = 17.2°C).
- 1150 h: Snake began to approach lizard from rear, and lizard began to move away slowly from snake; both stopped after a few seconds.
- 1157 h: Lizard resumed moving away from snake, stopping about 50 cm from snake.
- 1217 h: Lizard opened and closed mouth several times in quick succession.
- 1222 h: Snake resumed approach toward lizard (with occasional tongueflicks), approaching to within 10 cm.
- 1234 h: Lizard did not move; snake retreated.
- 1237 h: Snake approached again, closing to within 1 cm of the lizard.
- 1245 h: Lizard pushed its head into head of *C. aquilus*; no overt response from snake. Lizard shifted position, settling its head on midsection of snake.
- 1250 h: Snake began to encircle lizard, which briefly settled over the body of the snake more fully, then moved away from the snake again.
- 1253 h: Snake bit lizard on head; lizard shook its body and the snake retreated.
- 1258 h: Snake bit lizard again on the head; female lizard shook its body again and placed its body over snake.
- 1316 h: Snake began to move again; lizard started to move away again.
- 1330 h: Lizard moved off of dirt path into nearby shrubby vegetation, climbing onto top of cluster of small herbaceous plants (*Salvia* sp.). Snake was about 10 cm away.
- 1348 h: Snake briefly moved toward lizard again.
- 1351 h: Lizard began to lose grip on vegetation.
- 1402 h: Lizard fell onto ground, ventral side up and was motionless.
- 1404 h: Leg of lizard began to twitch. Spasms lasted about three minutes.
- 1410 h: Snake resumed approach to lizard with tongueflicks.
- 1420 h: Snake bit head of lizard again, and began to consume it headfirst.
- 1436 h: Swallowing of lizard complete.

The behavior of the lizard when found suggests that it was envenomated prior to discovery. However, the lengthy duration between a probable initial strike and lizard death (≥ 3 h) suggests that relatively little venom may have been injected. (The bites that we observed did not appear to be feeding strikes, but perhaps attempts to determine whether the prey was ready to be consumed.)

The second observation occurred on 25 August 2008 in similar open, shrubby habitat. At 1135 h, two of us (BPS and NI) found a *C. aquilus* adult consuming an adult male *S. minor* (air temperature = 16.2°C). When discovered, the snake had swallowed approximately 50% of the lizard, which was oriented ventral-side up as in the previous observation. The snake was found at the base of a limestone boulder, but retreated into nearby vegetation upon approach. By 1147 h the snake had consumed the lizard down to the base of the tail.

On several other occasions we found individuals of *S. minor* or the sympatric congener *S. torquatus* lying motionless on the ground or on rock piles with no visible wound. Close inspection of the immediate area often revealed a *C. aquilus* nearby (< 1 m) suggesting that these individuals had been recently envenomated but not yet consumed. Overall, these observations are consistent with several other reports of predation by *C. aquilus* on *Sceloporus* lizards (Klauber 1997. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. 2nd ed. University of California Press, Berkeley, California; Mociño-Deloya et al. 2008. Herpetol. Bull. 105:10–12), indicating that *Sceloporus* lizards are probably an important food source throughout the range of *C. aquilus*.

We thank SEMARNAT and the Government of México for providing research permits, and also funding the project FOMIX-HGO-2008-95828 “Diversidad Biológica del Estado de Hidalgo.” The Municipality of Zimapán, Hidalgo, and the Bienes Comunales of La Encarnación provided additional logistical assistance.

STENOCERCUS GUENTHERI **(**Günther's Whorltail Iguana). **REPRODUCTION.** *Stenocercus guentheri* is known from the Andes of Ecuador and Colombia (Torres-Carjaval 2000. Sci. Pap., Nat. Hist. Mus. Univ. Kansas 15:1–38). Information on *S. guentheri* reproduction consists of clutch size reports of two eggs deposited in May and June (Fritts 1974. San Diego Soc. Nat. Hist. Mem. 7:1–89; Torres-Carjaval, *op. cit.*). The purpose of this note is to report a minimum SVL for maturity in females and the first information on the testicular cycle for *S. guentheri.*

Six females (mean SVL = 64.8 mm ± 5.9 SD, range = 58–70 mm) and three males (mean SVL = 73.3 mm ± 5.8 SD, range = 70–80 mm) of *S. guentheri* were borrowed for histological gonad examination from the herpetology collection of the Natural History Museum of Los Angeles County (LACM). The specimens were collected in 1977 (Colombia) Tangua, Nariño Province (1.08333°N, 77.30000°W, datum WGS84; elev. 2286 m) (LACM 131492) and in 1970 (Ecuador), El Quinché, Pichincha Province (0.25000°S, 78.41666°W, datum WGS84; elev. 2591 m) (LACM 58782–58789).

The left gonad was removed for histological examination and embedded in paraffin. Histological sections were cut at 5 μm, mounted on glass slides and stained with Harris hematoxylin followed by eosin counterstain. Histology slides were deposited in LACM.

Four of the six females (SVL = 63–70 mm) each (from May) contained clutches of two oviductal eggs. The remaining two females (each SVL = 58 mm) contained quiescent ovaries with no yolk deposition. The minimum size for female reproductive activity was 63 mm SVL (LACM 58783). Previous records of clutch sizes of two (Fritts, *op. cit.*; Torres-Carjaval, *op. cit.*) suggest this may be typical for *S. guentheri.* However, there are reports of congeneric species of *Stenocercus* producing larger clutches: *S. humeralis* (four eggs) (Torres-Carvajal, *op. cit.*); *S. azureus* (six eggs) (Torres-Carjaval 2004. Herpetol. Rev. 35:172); *S. doellojuradoi* (six eggs) (Pelegrin and Bucher 2010. Herpetol. Rev. 41:86–87).

The three male *S. guentheri* (SVL = 70–80 mm, two from May and one from November) exhibited spermiogenesis. Lumina of the seminiferous tubules were lined by spermatozoa and clusters of metamorphosing spermatids. The minimum size for reproductive activity was 70 mm SVL (LACM 58784, 131492). The presence of males undergoing spermiogenesis at opposite ends of the year (May and November) suggests *S. guentheri* exhibits a prolonged period of sperm formation.

I thank Christine Thacker (LACM) for permission to examine *S. guentheri.*

Submitted by **STEPHEN R. GOLDBERG,** Biology Department, Whittier College, PO Box 634, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

STENOCERCUS GUENTHERI (Günther's Whorltail Iguana). **ENDOPARASITES.** *Stenocercus guentheri* is known from the Andes of Ecuador and Colombia (Torres-Carjaval 2000. Sci. Pap., Nat. Hist. Mus. Univ. Kansas 15:1–38). To our knowledge, there are no reports of endoparasites from *S. guentheri.*

Five specimens of *S. guentheri* (mean SVL = 72.4 mm ± 8.9 SD, range = 63–82 mm) were borrowed for helminthological examination from the herpetology collection of the Natural History Museum of Los Angeles County (LACM). They were collected in May 1970 from El Quinché, Pinchincha Province, Ecuador (0.25000°S, 78.41666°W, datum WGS84; elev. 2591 m): LACM 58782, 58784, 58790, 58807, 58808.

The body cavity was opened and the digestive tract was removed, opened by a longitudinal incision, and examined under a dissecting microscope. One species of Cestoda, two species of Nematoda, and one species of Acanthocephala were found. All were studied under a compound microscope and identified. The cestodes (N = 3, from the small intestines) were regressively stained in hematoxylin, mounted in Canada balsam, and identified as *Oochoristica travassosi*, prevalence = number infected lizards/number lizards studied × 100 = 60%; mean intensity = mean number parasites per infected lizard = 1.7 ± 0.58 SD; range = 1–2. Nematodes and acanthocephalans were cleared in glycerol on a microscope slide, cover-slipped, and identified as *Physaloptera retusa* (N = 48 from the stomach, N = 1 from the small intestine) prevalence = 100%; mean intensity = 9.8 ± 6.8 SD; range = 4–21; acuariid larvae (N = 9 from the body cavity) prevalence = 20%; and acanthocephalan cystacanths (N = 7 from the body cavity) prevalence = 20%.

Helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as: *Oochoristica travassosi* (103199); *Physaloptera retusa* (103200): acuariid larvae (103201), acanthocephalan cystacanths (103202).

Oochoristica travassosi was described from *Leiocephalus* sp. from Peru by Rego and Ibáñez (1965. Mem. Institut. Oswaldo Cruz 63:67–73). It has previously been found in *Liolaemus vallecurensis* from Argentina (Goldberg et al. 2004. Comp. Parasitol. 71:208–214) and *Phyllodactylus johnwrighti* from Peru (Goldberg and Bursey 2010. Comp. Parasitol. 77:91–93). Conn (1985. J. Parasitol. 71:10–16) reported beetles served as intermediate hosts for the congeneric *O. anolis. Physaloptera retusa* is widely distributed in New World lizards and has been reported from both North and South America (Goldberg et al., *op. cit.*). Like other members of the Physalopteridae, it utilizes insect intermediate hosts (Anderson 2000. Nematode Parasites of Vertebrates. 2nd ed. CAB International, Oxfordshire, UK. 650 pp.). Adults of the Acuariidae occur in the gizzard of terrestrial birds; insects are intermediate hosts (Anderson 2000, *op. cit.*). Lizards likely serve as paratenic (transport) hosts with development completed in an avian final host. Acanthocephalans require an invertebrate intermediate host in which the cystacanth develops, infective to the final host (Kennedy 2006. Ecology of the Acanthocephala. Cambridge Univ. Press, Cambridge, UK. 249 pp.). Because no further development occurs, lizards most likely are paratenic

hosts. *Stenocercus guentheri* represents a new host record for *Oochoristica travassosi*, *Physaloptera retusa*, acuariid larvae, and acanthocephalan cystacanths.

SRG thanks Christine Thacker (LACM) for permission to examine *S. guentheri* and Cecilia Nava (Whittier College) for assistance with dissections.

BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

TROPIDURUS TORQUATUS (Lagartixa, Calango). **DIET**. *Tropidurus torquatus* is a common and widespread lizard that occurs in many habitats in central and southern regions of Brazil and neighboring countries (Rodrigues 1987. Arq. Zool. S. Paulo 31:105–230), including urban areas. It is a sit-and-wait predator that preys mainly on arthropods, but also consumes plant material and vertebrates (Bergallo and Rocha 1994. Austral. J. Ecol. 19:72–75; Teixeira and Giovanelli 1999. Rev. Bras. Biol. 59:11–18). However, few dietary studies have included data from within urban environments. Herein we report the diet of *T. torquatus* in an urban area in Brazil.

Lizards were collected between August and October of 2006, in four urbanized sites in the city of Itabira, Estado de Minas Gerais, southeastern Brazil (19.665ºS, 43.212ºW). Itabira harbors a human population of about 100,000 (IBGE 2006, available at http://www.ibge.gov.br/cidadesat/) settled in the Atlantic Rainforest domain, but the surrounding areas are highly impacted by anthropogenic activities, especially mining. All four sites are characterized by housing, paved surfaces, vacant lots, and trash consisting of construction materials. The stomachs of 20 lizards (12 male, 8 female), with SVL averaging 87.5 mm ± 23.5 SD (range 51.8–133.8 mm), were examined by dissection; all specimens had food remnants in their stomachs. Eusocial insects (ants and termites) were by far the most important prey both in numbers (N = 261, 48.6% of total prey items and N = 224, 40.7% of total prey items, respectively) and frequency in which prey was recorded (N = 17, 85% and N = 11, 55%, respectively). Ants and termites were followed by bees in number (N = 33, 6%) and frequency (N = 8, 40%). Also found were remains of beetles (number: N = 7, 1.3%; frequency: N = 2, 10%), crickets (number: N = 3, 0.5%; frequency: N = 1, 5%), cockroaches (number: N = 3, 0.5%; frequency: N = 1, 5%), unidentified arthropods (number: N = 12, 2.2%; frequency: N = 2, 10%), and insect pupae (number: N = 2, 0.4%; frequency: N = 1, 5%). Plant material was represented by flowers (number: N = 1, 0.2%; frequency: N = 1, 5%).

The predominance of eusocial insects in the diet of *T. torquatus* is in accordance with previous studies (Bergallo and Rocha, *op. cit.*; Fialho et. al. 2000. J. Herpetol. 34:325–330). This species seems to be a generalist lizard that invests in the most abundant prey available (Arruda et al. 2007. *In* Anais do VIII Congresso de Ecologia do Brasil: 1–2). Ants and termites, being highly mobile and normally locally abundant, are usually predominant in its diet (Fialho et al., *op. cit.*), which seems to hold true for this study in an urban environment.

Submitted by **BRENO D. DE SOUZA**, Fundação Comunitária do Ensino Superior de Itabira, Itabira, MG, CEP 35900-842, Brazil (e-mail: bdsbio@yahoo.com.br); and **FERNANDO A. PERINI**, Laboratório de Biodiversidade Molecular, Departamento de Genética, Instituto de Biologia, Universidade Federal do Rio de Janeiro, CP 68011, Rio de Janeiro, RJ, CEP 21941-590, Brazil (e-mail: faperini@yahoo.com.br).

SQUAMATA — SNAKES

ACANTHOPHIS PYRRHUS (Desert Death Adder). **FORAGING BEHAVIOR.** *Acanthophis pyrrhus* is a short-bodied terrestrial elapid restricted to hummock grassland habitats across Australia's arid to semi-arid zone (Wilson and Swan 2003. A Complete Guide to Reptiles of Australia. New Holland Publishers. Sydney, New South Wales. 512 pp.). Both in morphology and ecology, members of this genus are highly convergent with vipers (Shine 1980. Herpetologica 36:281–289). One similarity is the presence of a pale tail tip on some species which is reportedly used to lure prey (Chiszar et al. 1990. J. Herpetol. 24:253–260). However, to my knowledge, caudal luring has only been reported in two species of death adder (*A. antarcticus*, *A. praelongus*) and has not been reported in the wild for any species (Carpenter and Carpenter 1978. J. Herpetol. 12:574–577; Hagman et al. 2008. Funct. Ecol. 22:1134–1139; Chiszar et al., *op. cit.*). Here, I report on two possible examples of caudal luring observed in wild *A. pyrrhus* encountered on Namatjira Drive (west of Alice Springs in the Northern Territory, Australia) while road-cruising as part of a broader study of arid-zone snakes.

On the 18 September 2009, at 1909 h, I encountered a small adult female *A. pyrrhus* (SVL = 389 mm) coiled on the road surface with its entire tail extending vertically into the air. The animal remained motionless in this position for several minutes before lowering its tail and attempting to move off the road surface, presumably in response to my presence. No independent movement of the tail tip was observed. On the following night, at 2022 h, I encountered a larger adult female *A. pyrrhus* (SVL = 560 mm) exhibiting the same posture as the animal from the previous night (Fig. 1). I observed the snake for approximately 10 minutes during which time the tail tip was wriggled intermittently while the remainder of the tail was maintained in the vertical

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Adult female *Acanthophis pyrrhus* coiled on the road surface with its tail extending vertically into the air.

position. After 10 min the snake lowered its tail and moved off the road. In both situations I find it unlikely that the snake's tails were extended into the air in response to the approach of my vehicle, as they were spotted in this position at considerable distance (approximately 50 m).

Holding the tail in an erect position has been reported for captive *A. antarcticus* and was considered to be a posture related to caudal luring (Carpenter and Carpenter, *op. cit.*). By lying in an exposed situation (road surface) with the tail erect, *A. pyrrhus* may attract prey from a greater distance than they would by laying among dense vegetation or with their tail on the ground. However, the potential cost (predation risk and road mortality) of such behavior may also be high. Alternative hypotheses for the behavior include reproduction (e.g., broadcasting for males), predator warning, or predator diversion (Greene 1973. J. Herpetol. 7:143–161).

Work was carried out under scientific permit no. 33584 from the Northern Territory Government and was approved by the Animal Care and Ethics Committee (ANZCCART) of Charles Sturt University (Ref: 09/064).

Submitted by **PETER J. McDONALD**, Biodiversity Conservation Unit, Northern Territory Government, P.O. Box 1120, Alice Springs, Northern Territory 0871, Australia; e-mail: peterj.mcdonald@nt.gov.au.

AGKISTRODON BILINEATUS (Cantil). **ENDOPARASITES.** *Agkistrodon bilineatus* occurs from near sea level to about 1500 m elevation along the Pacific Coast from Sonora, Mexico, southward through northern Costa Rica, but is disjunctly distributed along the Atlantic Coast from the Yucatan Peninsula through Guatemala (Lee 2000. A Field Guide to the Amphibians and Reptiles of the Maya World. Cornell Univ. Press, Ithaca, New York. 402 pp.). We know of no helminths reported from *A. bilineatus*. The purpose of this note is to establish the initial helminth list for *A. bilineatus.*

The coelomic cavities of two female *A. bilineatus* from Mexico (SVLs = 543, 563 mm) were examined from the herpetology collection of the Los Angeles County Natural History Museum (LACM): LACM 59184, Tamaulipas, 84 km N Mante (22.7500°N, 99.0000°W, datum WGS84; elev. 104 m) collected June 1965; and LACM 74046, Sinaloa, Coyotitán (23.7833°N, 106.5833°W, datum: WGS84; elev. 91 m) collected November 1964. Two nematodes (LACM 74046) and one larval acanthocephalan (LACM 59184) were found. Nematodes and the acanthocephalan were cleared in a drop of glycerol on a microscope slide, coverslipped, and identified: one female *Hastospiculum onchocercum*; one third stage ascaridid (Angusticaecinae) larva, and one oligacanthorhynchid acanthocephalan cystacanth. Helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as *Hastospiculum onchocercum* (USNPC 102284), ascaridid (Angusticaecinae) larva (USNPC 102285), and acanthocephalan cystacanth (USNPC 102286).

Hastospiculum onchocercum is limited to a variety of snakes from the New World tropics (Goldberg and Bursey 2004. Carib. J. Sci. 40:62–69). *Hastospiculum* is a member of the Diplotriaenoidea, which utilizes insects as intermediate hosts (Anderson 2000. Nematode Parasites of Vertebrates. Their Development and Transmission. CABI Publishing, Wallingford, UK. 650 pp.). Snakes presumably acquire *H. onchocercum* when they ingest prey which have eaten infected insects.

Three genera of ascaridid nematodes have been reported from snakes collected in Central America (Baker 1978. Synopsis of the Nematoda Parasitic in Amphibians and Reptiles. Memorial University of Newfoundland, Occas. Pap. Biol. 11:1–325). Third stage larvae of these three genera are morphologically indistinguishable. *Agkistrodon bilineatus* likely serves as a final host. Infection was most likely acquired by ingestion of an infected transport (paratenic) host, such as a grasshopper, frog, lizard, or rodent (Anderson, *op. cit.*).

Oligacanthorhynchid acanthocephalan cystacanths are frequently found in the coelomic cavities of snakes (Goldberg and Bursey, *op. cit.*). Snakes are inappropriate final hosts for cystacanths and likely serve as transport hosts. *Agkistrodon bilineatus* represents a new host record for *Hastospiculum onchocercum*, ascarid larva, and oligacanthorhynchid acanthocephalan cystacanths.

We thank Christine Thacker (LACM) for permission to examine *A. bilineatus.*

COLUBER* (= *MASTICOPHIS*) *FLAGELLUM TESTACEUS (Western Coachwhip). **DIET**. *Coluber flagellum testaceus* feeds on lizards, small mammals, snakes, birds and their eggs, and large arthropods (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.; Werler and Dixon 2000. Texas Snakes. Univ. Texas Press, Austin. 437 pp.). It has also been reported that *C. f. testaceus* feed upon small lagomorphs including *Lepus californicus* and nestling *Sylvilagus* rabbits (Whiting et al. 1992. The Snake 24:157–160) Here, we report our observation of a *C. f. testaceus* feeding upon

FIG. 1. Adult *Coluber* (= *Masticophis*) *flagellum testaceus* on first attempt at feeding upon a juvenile *Sylvilagus audubonii* (Desert Cottontail) in Big Bend National Park, Texas, USA.

a juvenile *Sylvilagus audubonii* (Desert Cottontail).

Before noon on 29 April 2006, we discovered an adult *C. f. testaceus* apparently perched 1 m off the ground in the midsection of a mesquite bush (*Prosopis glandulosa*) near the Panther Junction Visitor Center in Big Bend National Park, Texas, USA (29.3281°N, 103.2064°W, datum WGS 84; elev. 1138 m). The snake was slightly moving its head near the branching point of one of the limbs. Upon closer investigation we noticed that it was consuming a juvenile *S. audubonii* (Fig. 1). The snake attempted to consume the rabbit, though the branch obstructed its success twice. Eventually, the snake turned its head to the other side of the branch and fully consumed the young rabbit. The observation lasted for more than 30 minutes before the snake finally crawled to the ground and slowly slithered away. This observation documents the first record of *C. f. testaceus* feeding upon *S. audubonii*.

LEAVITT**, Texas Cooperative Wildlife Collection, Department of Wildlife and Fisheries Science, Texas A&M University, College Station, Texas 77843-2258, USA (e-mail: dlea886@tamu.edu); and **ROBERT H. DEAN**, Division of Interpretation, Big Bend National Park, Texas 79834, USA.

CONOPHIS LINEATUS (Road Guarder). **DIET**. *Conophis lineatus* is a rear-fanged, diurnal Central American colubrid with a varied diet. Though *C. lineatus* is likely an opportunistic predator, field observations and dissections of museum specimens are mostly of lizard prey (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. University of Chicago Press, Chicago, Illinois. 954 pp.; Stafford and Henderson 2006. S. Am. J. Herpetol. 1:210–217). On 21 June 2002, at ca. 1500 h, in Santa Rosa National Park, Guanacaste Province, Costa Rica (10.8392°N, 85.6184°W, datum NAD83), I observed an adult *C. lineatus* in an open lowland dry forest adjacent to a gravel road. The snake had struck a toad, *Bufo luetkenii*, and was grasping it in its mouth (Fig. 1). The snake kept the toad pinned to the ground for ca. 15 min and then began ingesting it head first. Ingestion took ca. 25 min, after which the snake crawled away into denser vegetation. I believe this observation represents the first time *C. lineatus* has been reported feeding on *B. luetkenii* and may represent the first record of *C. lineatus* feeding on any toad species in the wild. Photographic vouchers were verified by Twan Leenders and deposited at Yale Peabody Museum of Natural History, Herpetology media records YPM M 1211–1214.

FIG. 1. *Conophis lineatus* feeding on a toad, *Bufo luetkenii*, in Guanacaste National Park, Costa Rica.

CROTALUS CATALINENSIS (Santa Catalina Island Rattlesnake). **REPRODUCTION.** *Crotalus catalinensis* is endemic to Isla Santa Catalina, Baja California Sur, Mexico. Although observations exist of wild female *C. catalinensis* in various reproductive states (Grismer 2002. Amphibians and Reptiles of Baja California, Including its Pacific Islands and the Islands in the Sea of Cortés. Univ. California Press, Berkeley. 399 pp.), reproductive data for *C. catalinensis* are limited. To date, the only published accounts of litter size for *C. catalinensis* include: a female collected in early August that produced two young (Grismer, *op cit*.); seven young born at Fresno Zoo on 8 July 1980 (Tremper 1981. *In* 5th Annual Reptile Symposium on Propagation and Husbandry, pp. 70–75. Oklahoma City Zoo, Oklahoma City); a single *C. catalinensis* born on 1 October 1964 at the San Diego Zoo (San Diego Zoonooz, November 1964); nine young born at the Frankfurt Zoo (Anonymous 1988. Aquarien-und Terrarien-Zeitschrift 41:328); seven young born to a captive female (G. Keasler, pers. comm. 2009); and three young born at the San Diego Zoo from a wild collected female (Boyer and Kinkaid, pers. comm. 2009). Herein, we describe a litter born to a wild collected *C. catalinensis* maintained in captivity at the Los Angeles Zoo and Botanical Gardens.

On 23 April 2009, we collected an adult (SVL = 71.12 cm; 272 g) gray phase female *C. catalinensis* on the southwest side of Isla Santa Catalina, 25.6023°N, 110.7791°W, WGS 84; elev. 0 m. This animal was transferred to Los Angeles Zoo and Botanical Garden and placed into the zoo's quarantine facility and maintained in a 20-gallon terrarium supplied with a 24-h sub-floor heated basking area and a hide box. Between 3 May and 10 June 2009 she consumed eight whole pre-killed adult mice. She refused to feed on 21 June and continued to refuse food until parturition. On 9 August a dorsal whole body radiograph was taken and showed several embryonic skeletons. On 13 August 2009, six neonates (one male, five female; mean mass 15.2 g; range 14.8–16.3 g), were found inside the hide box with the female. The litter consisted of three brown phase and three gray phase neonates.

We thank the many people of Mexico who assisted us, SEMARNAT, and the Mexican government for allowing access to Isla Santa Catalina. All research and collecting were done under the authority of SEMARNAT scientific research permit SGPA/DGVS/03804, issued to IR.

Herpetología, Apartado Postal-513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México (e-mail: dlazcanov@hotmail.com).

EPICRATES CENCHRIA (Salamanta; Rainbow Boa). **DIET**. Snakes in the genus *Epicrates* are dietary generalists, feeding on both endothermic and ectothermic prey, particularly lizards, mid-sized mammals, and birds (Henderson et al. 1987. Amphibia-Reptilia 8:251–258). The genus is endemic to the New World Neotropics and contains 14 species (Passos and Fernandes 2008. Herpetol. Monogr. 22:1–30). *Epicrates cenchria* occurs in forested regions of the Amazon Basin of Colombia, Ecuador, Peru, Bolivia, Venezuela, Guyana, Suriname, French Guyana, and Brazil and in a disjunct population in the Atlantic rainforest of Brazil, from Alagoas to Rio de Janeiro states (Passos and Fernandes, *op. cit.*). Until recently, *E. cenchria* was subdivided into nine subspecies (McDiarmid et al. 1999. Snakes Species of the World: A Taxonomic and Geographical Reference, Vol. 1. The Herpetologist's League, Washington, DC), but a taxonomic revision based on external morphology, osteology, and hemipenis characters rearranged this complex into five species that inhabit the South American continent: *E. alvarezi*, *E. assisi*, *E. cenchria*, *E. crassus*, and *E. maurus* (Passos and Fernandes, *op. cit.*). The remaining species in the genus are restricted to islands in the West Indies (Kluge, *op. cit.*; McDiarmid et al., *op. cit.*).

Several works have documented ontogenetic shifts in the diet of some species in this genus. Diet of larger species varies ontogenetically, from specializing on anoline lizards when young to widely generalist feeding as adults (e.g., Chandler and Tolson 1990. J. Herpetol. 24:151–157; Henderson et al., *op. cit.*; Sheplan and Schwartz 1974. Ann. Carnegie Mus. Nat. Hist. 45:57–143; Wiley 2003. Carib. J. Sci. 39:189–194). For the newly split *E. cenchria* complex, *E. assisi* from the Caatinga biome of Brazil eats mammals, bird eggs, and lizards. *Epicrates crassus* from the Brazilian Cerrado biome feeds on birds and mammals. *Epicrates cenchria* preys on mammals, mainly rodents, birds, bird eggs, bats, frogs, and lizards (see Pizzato et al. 2009. Amphibia-Reptilia 30:533–544, and references therein). There are no records on the diet of the other continental species. Herein, we record an additional and unusual prey item for the genus *Epicrates*.

On a morning in March 2001, JC collected a large (total length = 175 cm; tail length 20.8 cm) *E. cenchria* crossing a trail in a remnant of Atlantic rainforest (19.735914°S, 41.824673°W, datum WGS84; elev. ca. 455 m) at Reserva Particular do Patrimônio Natural Feliciano Miguel Abdala (RPPN-FMA), Caratinga municipality, Minas Gerais state, southeastern Brazil. Examination of the stomach contents of this specimen revealed an unusual food item, a quill of an unidentified porcupine (Erethizontidae: Rodentia: Mammalia). This represents a new diet record for the genus *Epicrates*. Predation on porcupines has been described for several other snakes, mostly in the family Boidae (Cherubini et al. 2003 J. Venom. Anim. Toxins 9:117–124; Duarte 2003 Phyllomedusa 2:109–112). The snake was deposited in the herpetological collection of the Museu de Zoologia da Universidade de São Paulo (MZUSP 14474; J. Cassimiro field number JC 517).

We are grateful to Bárbara N. Costa for help in the identification of the prey item. Felipe F. Curcio verified snake identification. JC also thanks Karen B. Strier for providing facilities during fieldwork and for funding during his work in the RPPN-FMA through the following institutions: Margot Marsh Biodiversity Foundation, Liz Claiborne and Art Ortenberg Foundation, National Geographic Society, and Graduate School of the Wisconsin-Madison University.

LEPTOTYPHLOPS AUSTRALIS (NCN). **PREDATION**. Burrowing Owls (*Athene cunicularia*) are known to include snakes and other reptiles in their diet (König et al. 1999. Owls: A Guide to the Owls of the World. Yale Univ. Press, New Haven, Connecticut. 462 pp.). On 25 October 2008, on Provincial Road 7, 20 km E Paso Cordova, Departamento El Cuy, Rio Negro Province, Argentina (39.1818ºS, 67.4053ºW, datum WGS84; elev. 405 m), a set of regurgitated *A. cunicularia* pellets was collected near an active owl burrow. Laboratory study revealed remains of four snakes in the pellets, all identified as *Leptotyphlops*. The damage inflicted to the heads of the specimens made identification to species level difficult, but the coloration, morphometrics, and scale patterns of the individuals were consistent with *L. australis* (Cei 1986. Reptiles del Centro, Centro-Oeste y Sur de la Argentina. Mus. Reg. Sci. Nat. Torino, Mon. 4. 527 pp.). This represents the first record of predation on *L. australis* by Burrowing Owls.

Submitted by **ANAHI FORMOSO, DARIO PODESTA**, and **LUCIANO JAVIER AVILA** (e-mail: avila@cenpat.edu.ar), CENPAT-CONICET, Boulevard Almirante Brown 2915, U9120ACD, Puerto Madryn, Chubut, Argentina.

MICRURUS FULVIUS (Harlequin Coralsnake). **DIET**. *Micrurus fulvius* is known to prey upon amphisbaenids, anguids, scincids, elapids, and colubrids (Jackson and Franz 1981. Herpetologica 37:221–224), however it has not been documented preying upon nonindigenous species. Herein, we document *M. fulvius* preying upon a *Ramphotyphlops braminus* (Brahminy Blindsnake).

On 1 September 2009, a *M. fulvius* (female; SVL = 38.7 cm) was found dead-on-road (DOR) at the Pine Island maintenance area in Everglades National Park, Miami-Dade Co., Florida, USA (25.384178°N, 80.594128°W, datum WGS84; elev. <1 m), and was deposited in the Florida Museum of Natural History, University of Florida (UF 156838, EVER 40584). Upon taking a tissue sample from an opening likely caused by vehicle impact, we noticed a foreign body protruding from the snake's abdomen.

This object was removed and identified as a nonindigenous *R. braminus*. In Florida, Wilson and Porras (1983. Univ. Kansas Mus. Nat. Hist., Spec. Publ. No. 9) first reported *R. braminus* from Miami-Dade Co., and this species has been reported to be preyed upon by *Lampropeltis extenuata* (Short-tailed Snake; Godley et al 2008. Herpetol. Rev. 39:473–474) and both the nonindigenous *Rhinella marina* (Cane Toad) and *Anolis cristatellus* (Puerto Rican Crested Anole; Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida. 155 pp.). This is the first record of *M. fulvius* consuming a nonindigenous snake in Florida.

Box 117800, University of Florida, Gainesville, Florida 32611, USA; and **RAY W. SNOW**, National Park Service, Everglades National Park, 40001 State Road 9336, Homestead, Florida 33034 USA.

OPISTHOTROPIS KUATUNENSIS (Chinese Mountain Keelback). **ENDOPARASITES.** *Opisthotropis kuatunensis* occurs in Zhejiang, Fujian, Jiangxi, and Hong Kong, China (Zhao and Adler 1993. Herpetology of China. SSAR, Oxford, Ohio. 522 pp.). It was first reported in Hong Kong in 1974 (Karsen et al. 1986. Hong Kong Amphibians and Reptiles. The Urban Council, Hong Kong. 136 pp.). To our knowledge, there are no reports of helminths from *O. kuatunensis*. The purpose of this note is to establish an initial helminth list for *O. kuatunensis*.

One female *O. kuatunensis* (SVL = 30.5 cm) was collected at New Territories, Hong Kong (22.24°N, 114.07°E, datum WGS 84; elev. 644 m) on 23 September 2009. The snake died the next day and was preserved in 70% ethanol. Sixteen swellings (5–10 mm) were noted along the length of the *O. kuatunensis*. Four of these were opened and each contained a yellowish, elongate parasite. Each was cleared in a drop of glycerol on a slide, cover slipped, studied under a compound microscope, and identified as nymphs of the pentastome *Kiricephalus pattoni.* Voucher helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland, USA as USNPC (102414).

Adult *K. pattoni* inhabit the lungs of various snakes, and nymphs have been reported in a wide variety of amphibians and reptiles (Riley and Self 1980. Syst. Parasitol. 1:127–140). John and Nadakal (1988. Invert. Repro. Devel. 14:295–298) proposed a probable three-host life cycle for *K. pattoni*, amphibian/lizard first intermediate host, snake second intermediate host, and snake definitive host. *Opisthotropis kuatunensis* represents a new host record, a probable second intermediate host, for *Kiricephalus pattoni.*

Submitted by **YIK-HEI SUNG,** Division of Ecology & Biodiversity, School of Biological Sciences, The University of Hong Kong, Pokfulam Road, Hong Kong, China (e-mail: heisyh@gmail.com); **CHARLES R. BURSEY,** Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu); and **STEPHEN R. GOLDBERG,** Whittier College, PO Box 634, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu).

PANTHEROPHIS OBSOLETUS (Texas Ratsnake). **DIET AND FEEDING BEHAVIOR**. *Pantherophis obsoletus* is a common colubrid that feeds extensively on birds and mammals in the wild (Weatherhead et al. 2003. Am. Midl. Nat. 150:275–281) and will feed on dead rodents in captivity (MLM, pers. obs). However, observations of this species feeding on non-living anthropogenic sources of food are lacking. Each evening from mid-March through 25 April 2004, a single *P. obsoletus* (37 cm total length) returned to the back porch of the home at 2347 Pamela Dr., Chandler, Smith Co., Texas, USA (32.217°N, 95.506°W; NAD 1983), where it ate canned dog food from the dog's bowl and then departed. This observation adds to our understanding of the opportunistic nature of this species.

Submitted by **KEITHA PARKER**, Redwater Independent School District, 202 Red River Road North, P.O. Box 347, Redwater, Texas 75573, USA (e-mail: KParker@redwaterisd.org); and **MALCOLM L. McCALLUM**, 117 Linda Lane, Texarkana, Texas 75501, USA (e-mail: malcolm.mccallum@herpconbio.org).

SISTRURUS CATENATUS (Massasauga). **FEMALE SPERM EVACUATION**. During mating, a single male transfers more sperm than necessary to fertilize the available ova of a female (Halliday and Arnold 1987. Anim. Behav. 35:939–941). This, coupled with the fact that females typically mate with several males during a single mating period (Uller and Olsson 2008. Mol. Ecol. 17:2566–2580), results in an abundance of sperm in the female reproductive tract. In many taxa, including reptiles, females often store this sperm for long periods (months to years) in specialized receptacles, sperm storage tubules (SST), in the infundibulum prior to fertilization (Sever and Hamlett 2002. J. Exp. Zool. 292:187–199). However, the fate of unsuccessful sperm within the female reproductive tract remains largely unknown. A detailed description of sperm evacuation from SSTs is restricted to one study on *Thamnophis sirtalis parietalis* (Halpert et al. 1982. J. Morphol. 174:149–159) in which the authors noted that sperm in infundibular SSTs from fall matings were evacuated within six hours after a spring mating. Halpert et al. (*op. cit.*) state that sperm from the spring matings replaced the sperm from fall matings within the SSTs. The fate of the evacuated fall sperm was undetermined, though the authors noted that fall sperm stained less intensely with fast green; a phenomenon they believed indicative of sperm degradation. Blanchard and Blanchard (1941. Pap. Michigan Acad. Sci., Arts Lett. 26:177–193) and Schuett and Gillingham (1986. Copeia 1986:807–811) however, observed that sperm from fall matings can be used in fertilization the following spring in *T. s. sirtalis* and *Agkistrodon contortrix*, respectively.

Siegel and Sever (2008. J. Morphol. 269:189–206) provide the only detailed description of sperm transport and storage in a viper, *Agkistrodon piscivorus*, during the fall and subsequent spring mating periods. Siegel and Sever (*op. cit.*) found that sperm remained in *A. piscivorus* SSTs for up to 22 months following ovulation until the subsequent reproductive year at which time they were no longer observed. They hypothesized the mechanism for this disappearance to be either from spermiophagy by the SST epithelium or by the natural degradation of sperm; however, nei-

ther of these processes were observed. Additionally, Siegel and Sever (*op. cit.*) failed to observe the evacuation of sperm from SSTs following the spring mating season as described by Halpert et al. (*op. cit.*). The following account adds to the scant literature above by providing an incident of sperm evacuation in a female *Sistrurus catenatus*.

As part of a long-term study focusing on the conservation of *S. catenatus* in Butler Co., Pennsylvania, USA, free-ranging individuals were implanted with radio transmitters and monitored for a suite of ecological, behavioral (including mating activities), and physiological variables three times weekly. One female was initially encountered in May 2005 at which time an ultrasound revealed the presence of enlarged vitellogenic follicles indicating that she would likely give birth later in the year (birthed 19 August 2005). A fecal sample collected on 11 July 2005 to assess her general health and parasite load revealed something striking: numerous sperm (Fig. 1). Though isolated incidents of spring reproductive behavior have been reported in *S. catenatus* (Wright 1941. Am. Midl. Nat. 25:659–672; Jellen et al. 2007. J. Herpetol. 41:451–457), mating predominately occurs in the late summer–early fall period (Jellen et al., *op. cit.*; Johnson 2000. J. Herpetol. 34:186–192; Reinert 1981. Am. Midl. Nat. 105:393–395). If this sperm represents sperm from a recent mating, it would pre-date the earliest recorded date of summer reproductive behavior in *S. catenatus* by approximately two weeks (24 July; Jellen et al., *op. cit.*). Additionally, though male *S. catenatus* have been observed to engage in reproductive behaviors with pregnant females (Jellen et al., *op. cit.*), this female was never observed in the vicinity of a male nor exhibited any mating behaviors throughout the course of the year. However, because this individual was free-ranging, and consequently not under constant surveillance, an unobserved copulation during the active season prior to 11 July 2005 cannot be ruled out. A more plausible explanation, however, is that this observation represents the systematic oviductal evacuation of sperm from matings during (or prior to) the 2004 late summer–early fall mating period, which were unsuccessful in fertilizing ova in the spring of 2005.

Siegel and Sever (*op. cit.*) report that sperm degrade in the posterior oviduct prior to ovulation in vipers and describe the only storage site for sperm during pregnancy as within SSTs. Although a definitive mechanism for sperm evacuation was not observed in *A. piscivorus*, densities of sperm decreased in the SST over time until the subsequent mating season (Siegel and Sever, unpubl. data). A similar decrease in the presence of oviductal sperm following oviposition was observed in *Tantilla coronata* (Aldridge 1992. Amphibia-Reptilia 13:219–225). We propose that after ovulation, sperm are intermittently evacuated from SSTs. This process undoubtedly takes an extended period of time due to the lack of contractile elements associated with SSTs in snakes (for review see Siegel and Sever, *op. cit.*), and culminates with the eventual collection of sperm in the cloaca (a structure previously ignored in histological studies on sperm transport in snakes). Normal defecation then provides a proximate outlet for unsuccessful sperm in the female reproductive tract. We suggest that further histological and behavioral studies on sperm transport, storage, and evacuation are needed to confirm this phenomenon.

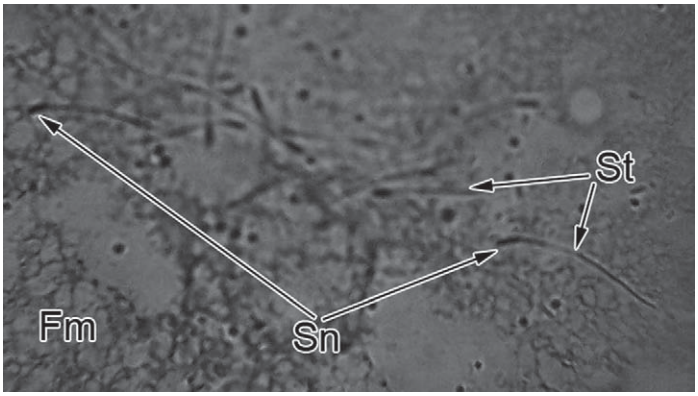

FIG. 1. Sperm in a pregnant female *Sistrurus catenatus* fecal sample collected 11 July 2005. Sn, sperm nucleus; St, sperm tail; Fm, fecal material.

Submitted by **BENJAMIN C. JELLEN**, Western Pennsylvania Conservancy, 800 Waterfront Drive, Pittsburgh, Pennsylvania 15222, USA; present address: Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA (e-mail: ben.jellen@gmail.com); **DUSTIN S. SIEGEL**, and **ROBERT D. ALDRIDGE**, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA.

THAMNOPHIS ATRATUS HYDROPHILUS (Oregon Gartersnake). **MAXIMUM ELEVATION**. *Thamnophis atratus* has been recorded at elevations up to 1920 m (6297 ft; St. John 2002. Reptiles of the Northwest. Lone Pine Publishing, Renton, Washington. 272 pp.). Here we report a population of *T. a. hydrophilus*, occurring entirely above this reported elevational limit in the Klamath Mountains, California, USA. Our observations occurred in upper Deep Creek Basin, Trinity Alps Wilderness, Trinity Co., California, USA (40.9176°N, 122.8876°W, datum NAD83). Deep Creek Basin is a medium-sized glacial characterized cirque (342 ha) encompassed by steep jagged peaks reaching elevations up to 2497 m, which are among the highest in the Klamath Mountains.

We captured and individually marked 56 individual *T. a. hydrophilus* of various age classes during 2003–2006. We recaptured many of these individuals, with total captures reaching 127 over the four years of the study. All snakes were found in streams, ponds, and Echo Lake, at elevations ranging from 1960 to 2215 m. These observations expand the known vertical limit of *T. atratus* by 295 m (968 ft). Much of the Klamath Mountains including the Trinity Alps, Russian, Marble Mountain, and Siskiyou Wilderness areas contain similar aquatic habitats that exceed the known previous elevational limit for this species.

In lower elevation streams, native salmonid fishes are an important component of *T. a. hydrophilus* diet (Welsh and Lind 2000. J. Herpetol. 34:67–74). Over the last century, nonnative salmonids have been introduced into most of the naturally fishless high-elevation aquatic habitats in the Klamath Mountains (Welsh et al. 2006. Divers. Distrib. 12:298–309). Introduced salmonid prey in the region may have allowed *T. a. hydrophilus* to expand into these high-elevation habitats (Pope et al. 2008 Biol. Conserv. 141:1321–1331).

We are grateful for the expert field assistance of R. Bourque, C. Wheeler, and M. Larson. This research was supported by the US Forest Service and through grants from California Department of Fish and Game, the National Fish and Wildlife Foundation, and the Declining Amphibian Populations Task Force.

Submitted by **JUSTIN M. GARWOOD** (e-mail: jgarwood@dfg.ca.gov) and **HARTWELL H. WELSH JR.**, Redwood Sciences Laboratory, Pacific Southwest Research Station, USDA Forest Service, 1700 Bayview Drive, Arcata, California 95521, USA.

THAMNOPHIS PROXIMUS (Western Ribbon snake). **REPRODUCTION**. On 16 May 2008, we collected a DOR *Thamnophis proximus* 1.61 km N of the intersection of FM508 and FM1420 on FM1420, Cameron Co., Texas, USA (26.27957°N, 97.58657°W, datum NAD83). The snake was a gravid female (SVL = 786 mm; total length = 1059 mm) and appeared to have been killed less than 12 h previously. Removal of offspring revealed a fetal clutch size of 27. Offspring appeared well developed and just days away from parturition. The litter consisted of eleven males (mean ± SD SVL = 194.9 ± 4.2 mm, range = 188–201 mm) and sixteen females (mean ± SD SVL = 189.4 ± 5.63 mm, range = 179–199 mm). Female volume before removal of offspring was 200 mL and total offspring volume was 75 mL.

The clutch is remarkable for its large numerical size and large fetal clutch volume as well as the potential early parturition date. The earliest published date for *T. proximus* parturition is 23 June (Lancaster and Ford 2003. Texas J. Sci. 55:25–32). A fetal clutch size of 27 is reported as the maximum clutch size (Klein 1949. Herpetologica 5:17). Average clutch size is 10–15 (Werler and Dixon 2000. Texas Snakes: Identification, Distribution, and Natural History. Univ. Texas Press, Austin. 437 pp.). Although the preparturitient state of this litter precluded accurate assessment of relative clutch mass, the relative clutch volume (calculated as volume of offspring divided by volume of female without offspring; Shine 1980. Oecologica 46:92–100) for this female was 0.6. Female and offspring were deposited at the Texas Cooperative Wildlife Collection at Texas A&M University (TCWC 93027–93054). Identification was verified by Toby Hibbits.

Box 1033, Hendersonville, North Carolina 28793, USA (e-mail: snakesteve@gmail.com).

AMPHIUMA MEANS (Two-toed Amphiuma). USA: GEORGIA: Baldwin Co.: Bartram State Forest, ca. 0.63 km SW of the intersection between SR 112 and Carl Vinson Road SE, (33.016978°N, 83.207808°W; WGS84) 20 August 2010. Houston C. Chandler. Florida Museum of Natural History photo voucher (UF 159215).Verified by Dennis Parmley and John B. Jensen. First county record. Found on the piedmont at the northern edge of expected range (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.) and the northernmost county record in the Oconee River drainage.

Single juvenile captured and photographed at the shallow edge of a large pond.

Submitted by **HOUSTON C. CHANDLER**, Department of Biological and Environmental Sciences, Georgia College and State University, Milledgeville, Georgia 31061, USA; e-mail: houston_chandler@ecats.gcsu.edu

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). USA: ARKANSAS: Calhoun Co.: ~6 km N of Ouachita River off US 167 (33.388195°N, 92.496846°W; WGS 84). 11 June 2010. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 31557). New county record (Trauth et. al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). Juvenile was hand captured under a log in a small slough. This species has also been collected from Union Co. in southern Arkansas (Trauth et al. 2004, *op. cit.)*

Submitted by **MATTHEW B. CONNIOR**, Health and Natural Sciences, South Arkansas Community College, 300 S. West Avenue, El Dorado, Arkansas 71730, USA; e-mail: mconnior@southark.edu.

CRYPTOBRANCHUS ALLEGANIENSIS (Eastern Hellbender). USA: TENNESSEE: Grundy Co.: Collins River, specific local withheld. 6 August 2010. J. M. Butler, S. D. Layne, and K. J. F. Dunn. Verified by K. L. Krysko. UF 159136 photo voucher. New county record which fills gap between Warren and Marion counties (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Austin Peay State University, Clarksville, Tennessee). Specimen observed beneath large rock in shallow river run.

Submitted by **J. MICHAEL BUTLER** (e-mail: scutatum@gmail.com), **SHANE D. LAYNE** and **K. J. F. DUNN**, U.S. Forest Service, London, Kentucky 40744, USA**.**

EURYCEA GUTTOLINEATA (Three-lined Salamander). USA: GEORGIA: Murray Co.: jct. of Carters Rd. and Old U.S. Hwy 411, ca. 19 air km SSE Chatsworth (34.60750°N, 84.69378°W; NAD83). 22 May 2010. Christopher E. Skelton. Verified by John B. Jensen and Kenneth Krysko (UF 157837). First county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Single adult collected in a flooded wheel rut within a mowed field, on NW side of Old US 441. This area was probably an active part of the floodplain of the Coosawattee River which is less than 400 m SSE of the field. The river is highly regulated now (rarely floods) but the water table is very near the ground surface and the presence of numerous crayfish burrows suggests it is wet for much of the year.

Submitted by **CHRISTOPHER E. SKELTON** (e-mail: chris.skelton@gcsu.edu); and **HOUSTON C. CHANDLER**, Department of Biological and Environmental Sciences, Georgia College & State University, Milledgeville, Georgia 31061,USA.

EURYCEA QUADRIDIGITATA (Coastal Plain Dwarf Salamander). USA: ARKANSAS: Grant Co.: 3.2 km S of Grapevine off St. Hwy 35 (34.112373°N, 92.309875°W; WGS 84). 27 April 1991. H. W. Robison. Henderson State University Herpetological Collection (HSU 1553). Verified by R. Tumlison. New county record; partially fills a hiatus among Dallas, Hot Spring, and Saline counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). This is the first new county record for *E. quadridigitata* in the state since Trauth et al. (*op. cit.*); the species is now known from 18 counties of south Arkansas.

Submitted by **CHRIS T. McALLISTER**, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); and **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: ARKANSAS: Cleburne Co.: 2.4 km SW of Quitman, roadside ditch (35.361336°N, 92.231255°W; WGS 84). 12 May 2003. B. Deeds. Henderson State University Herpetological Collection (HSU 1555). Verified by R. Tumlison. New county record. Fills a distributional gap among Independence, Van Buren, and White counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). Since the publication of Trauth et al. (*op. cit.*), no less than nine new county records have been documented for this species in the state.

Submitted by **CHRIS T. McALLISTER**, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); and **HENRY W. SIREN INTERMEDIA NETTINGI (= *SIREN INTERMEDIA TEXANA*) (Western Lesser Siren; Rio Grande Lesser Siren). USA: TEXAS: McMullen Co.: Escondido Ranch, Pond No. 11 (28.0950°N, 098.7543°W). 19 March 2010. C. Giggleman, P.

Clements, A. Miller, J. Ingold, R. Hooten, and N. Mitton. Verified by Michael R. J. Forstner. TCWC 94269. New county record (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M University Press, College Station, Texas. 421 pp.). Eleven specimens were seined at ca. 1 m depth from a seasonal lentic system surrounded by brush-dominated vegetation.

Submitted by **AMBER MILLER**, U.S. Fish and Wildlife Service, Corpus Christi Ecological Services Office, 6300 Ocean Drive, Classroom West, Corpus Christi, Texas 78412-5837, USA.

ANURA — FROGS

ANAXYRUS AMERICANUS (American Toad). USA: TENNESSEE: Warren Co.: Tennessee Amphibian Monitoring Program (TAMP) Route 820515, Stop 4, Lawson Mill Road, 1.22 km NW of intersection with Hwy 127 (35.629081°N, 85.803814°W; WGS 84). 12 March 2010. Amy Tolley. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19013 audio). New county record (Redmond and Scott 1996. Austin Peay St. Univ. Center Field Biol. Misc. Publ. 12:1–94). Individual heard calling from a field with pond on residential land.

Submitted by **AMY TOLLEY**, 446 NYU Place, Murfreesboro, Tennessee 37128, USA.

ANAXYRUS DEBILIS (Green Toad). USA: NEW MEXICO: Curry Co.: Melrose, 0.11 km S of US Hwy 60/84 and 0.24 km W of State Route 267 (34.42276°N, 103.61801°W; NAD83/WGS84; elev. 1342 m). 13 August 2008. Ian W. Murray. Verified by J. Tomasz Giermakowski. University of New Mexico Museum of Southwestern Biology (MSB 75398, 75399). New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.). At ca. 2300 h during intermittent showers, thunder, and lightning, a large pool had formed, centered on a low portion of a dirt road immediately south of the railroad tracks. At least 15 male *A. debilis* and a lone *Scaphiopus couchii* were heard calling, and one amplectant pair of *A. debilis* was seen. Two males were collected.

Submitted by **IAN W. MURRAY**, MSC03 2020, Department of Biology, 1 University of New Mexico, Albuquerque, New Mexico 87131-0001, USA (e-mail: imurray@unm.edu); and **PETER E. HUMPHREY**, Harvard Medical School, Brigham & Women's Hospital Boston, Massachusetts 02115-6110, USA (e-mail: phumphrey@partners.org).

BRACHYCEPHALUS HERMOGENESI. BRAZIL: PARANÁ: Municipality of Guaraqueçaba: Reserva Natural Salto Morato (25.1666ºS, 48.2892ºW, WGS84; elev. 250–300 m). 26–29 November 2009. F. B. Oliveira and M. S. Pereira. Museu Nacional, Rio de Janeiro (MNRJ 67312–13). 27 April 2010. A. Candaten. MNRJ 67314. All verified by J. P. Pombal, Jr. This species was previously known to occur in Atlantic Rainforest areas from extreme southern Rio de Janeiro State (municipality of Parati) to southern São Paulo State (Verdade et al. 2008. J. Herpetol. 42:542–549). This note provides the first record for the state of Paraná and the southernmost for the species, extending its distribution ca. 120 km S of Ribeirão Grande and 130 km SW of the Estação Ecológica de Juréia-Itatins, the two previous southernmost confirmed records, both in the state of São Paulo (Verdade et al., *op. cit.*). Verdade et al. (*op. cit.*) also mentioned one specimen possibly referable to *B. hermogenesi* from Ilha do Cardoso, in extreme southern São Paulo State, but could not confirm the species identity because the specimen was "young and in poor condition," and thus refrained from extending the species' distribution further south. As Ilha do Cardoso lies only ca. 30 km east of the locality reported in the present note, and at about the same latitude, we consider it highly probable that the aforementioned specimen indeed represented *B. hermogenesi*.

CHIROMANTIS SIMUS (Annandale's Pigmy Tree Frog). BANGLDESH: MYMENSINGH DIVISION: Tangail District: Madhupur National Park (24.6886°N, 90.1489°E, elev. 135 m). 22 June 2010. M. K. Hasan, M. Kamal Hossain, M. M. Kabir, and Fahim Hassan. Wildlife Museum, Department of Zoology, Jahangirnagar University, Savar, Dhaka, Bangladesh (JUHG 0325). Photograph voucher, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC [IMG] 1.32a–1.32b). Verified by Indraneil Das. First record for Mymensingh Division, and westernmost record for Bangladesh. Other Bangladesh populations are recorded from Chittagong Hill Tracts (ca. 320 km to SE) (Asmat et al. 2003. Univ. J. Zool., Rajshahi, Bangladesh 22:141–143), and Sylhet Division (ca. 200 km to NE) (Kabir et al. 2009. Encyclopedia of Flora and Fauna of Bangladesh. Vol. 25. Amphibians and Reptiles. Asiatic Society of Bangladesh, Dhaka. 204 pp.) with no locality details, specimen number, or voucher photographs. Nearest records are from Assam (ca. 500 km to E), Mizoram (ca. 600 km to SE), and West Bengal (ca. 500 km to NW), all in India (Ahmed et. al. 2009. Amphibians and Reptiles of Northeast India. A Photographic Guide. Aaranyak, Guwahati. 168 pp.) Males observed calling between 1955–2040 h from bushes at ca. 1.7 m height, over harvested paddy field with stagnant rainwater at edge of mature *Shorea robusta* forest. Bangladesh Forest Department issued permits (CCF [Wildlife] 2M-37 [Part-3] / 2010/ 409) for this work.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: TENNESSEE: DeKalb Co.: Vaughn Lane, 0.42 km SW of jct Hwy 56 (35.933683°N, 85.814194°W; WGS 84). 12 March 2010. Amy Tolley. Austin Peay State University Museum of Zoology (APSU 19015 audio). New county record (Redmond and Scott 1996. Austin Peay St. Univ. Center Field Biol. Misc. Publ. 12:1–94). A chorus of multiple individuals was heard calling at a pond on agricultural land. Warren Co.: Tennessee Amphibian Monitoring Program (TAMP) Route 820515, Stop 1, Lawson Mill Road, 0.51 km NE of intersection with Hwy 127 (35.615157°N, 85.810378°W; WGS 84). 12 March 2010. Amy Tolley. APSU 19016 audio. New county record (Redmond and Scott 1996, *op. cit.*). A chorus of multiple individuals was heard calling in the vicinity of a pond on residential land. All identifications were verified by A. Floyd Scott.

Submitted by **AMY TOLLEY**, 446 NYU Place, Murfreesboro, Tennessee 37128, USA.

PSEUDACRIS FERIARUM (Upland Chorus Frog). USA: TENNESSEE: DeKalb Co.: Vaughn Lane, 1.03 km SW of jct Hwy 56 (35.929983°N, 85.809125°W; WGS 84). 12 March 2010. Amy Tolley. Austin Peay State University Museum of Zoology (APSU 19014 audio). New county record (Redmond and Scott 1996. Austin Peay St. Univ. Center Field Biol. Misc. Publ. 12:1–94). A small chorus was heard calling from a drainage ditch in an agricultural field along the road. Warren Co.: Tennessee Amphibian Monitoring Program (TAMP) Route 820515, Stop 1, Lawson Mill Road, 0.48 km NE of the intersection with Hwy 127 (35.613992°N, 85.811122°W; WGS 84). 20 February 2010. Amy Tolley. APSU 19012 audio. New county record (Redmond and Scott 1996, *op. cit.*). A chorus of multiple individuals was heard calling in the vicinity of a pond on residential land. All identifications were verified by A. Floyd Scott.

Submitted by **AMY TOLLEY**, 446 NYU Place, Murfreesboro, Tennessee 37128, USA.

RHINELLA MARINA (Cane Toad). USA: FLORIDA: St. Lucie Co.: Port Saint Lucie, 1692 SW Biltmore Street (27.29007°N, 80.36546°W; WGS84), elev. 5 m. 16 June 2010. Kenneth L. Krysko, Catherine A. Smith, Joseph P. Burgess. Verified by Kevin M. Enge. Florida Museum of Natural History (UF 157938–39). New county record (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida. 155 pp.). Two individuals (2.0 and 2.2 cm SVL, respectively) found under debris at 1200 h.

Submitted by **KENNETH L. KRYSKO** (e-mail: kenneyk@flmnh.ufl.edu), **CATHERINE A. SMITH**, Division of Herpetology, Florida Museum of Natural History, Dickinson Hall, University of Florida, Gainesville, Florida 32611, USA (e-mail: hellcat@ufl.edu); and **JOSEPH P. BURGESS**, Florida Department of Environmental Protection, GTM NERR, Ponte Vedra, Florida 32082, USA (e-mail: Joseph.Burgess@dep.state.fl.us).

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). USA: TENNESSEE: Warren Co.: Tennessee Amphibian Monitoring Program (TAMP) Route 820515, Stop 5, Lawson Mill Road, 0.79 km NNW of intersection with Hwy 127 (35.626944°N, 85.799339°W; WGS 84). 11 June 2009. Amy Tolley. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 18973 photograph). New county record (Redmond and Scott 1996. Austin Peay St. Univ. Center Field Biol. Misc. Publ. 12:1–94). Individual observed on side of the road.

Submitted by **AMY TOLLEY**, 446 NYU Place, Murfreesboro, Tennessee 37128, USA.

SCINAX STAUFFERI (Stauffer's Long-nosed Treefrog). MÉXICO: OAXACA: Municipality of Villa de Tututepéc de Melchor Ocampo: Lagartero (16.052432°N, 97.646336°W; WGS 84), elev. 9 m. 31 January 2005. Aurelio Ramírez-Bautista and Vicente Mata-Silva. Verified by Uriel Hernández-Salinas. Laboratory for Environmental Biology, Centennial Museum, University of Texas at El Paso photographic collection (G 2010.1.1). First municipality record that fills a 340 km gap between the closest published localities, 130 km to the ESE in the vicinity of San Pedro Pochutla, Oaxaca, and 210 km to the WNW near San Marcos, Guerrero (Duellman 2001. The Hylid Frogs of Middle America, Vol. 2. SSAR Contributions to Herpetology 18:i–x + 695–1159). The frog was found in grass on the floor of a coconut grove, ca. 200 m from a marsh.

Submitted by **VICENTE MATA-SILVA**. Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968, USA (e-mail: vmata@utep.miners.edu); **AURELIO RAMÍREZ-BAUTISTA**, Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo, A.P. 1-69 Plaza Juárez, Pachuca, Hidalgo, C.P. 42001, México (e-mail: aurelior@uaeh.reduaeh.mx); and **JERRY D. JOHNSON**, Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968, USA (e-mail: jjonhson@utep.edu).

SCAPHIOPUS COUCHII (Couch's Spadefoot). USA: NEW MEXICO: Curry Co.: Melrose, New Mexico, 0.11 km S of Hwy 60/84 and 0.24 km W of State Route 267 (34.42305°N, 103.61838°W; NAD83/WGS84), elev. 1342 m. 3 July 2003. Ian W. Murray and Peter E. Humphrey. Verified by J. Tomasz Giermakowski. University of New Mexico Museum of Southwestern Biology (MSB 75697). New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.). The specimen was found buried ~5 cm deep in moist sandy soil at the edge of a rain-filled pool in a rutted dirt road on the north side of the railroad tracks.

Numerous tadpoles, probably *S. couchii*, were evident in the puddle, but they were not keyed out.

Submitted by **IAN W. MURRAY**, University of New Mexico Biology Department, Albuquerque, New Mexico 87131, USA (e-mail: imurray@unm.edu); and **PETER E. HUMPHREY**, Harvard Medical School, Brigham & Women's Hospital, Boston, Massachusetts 02115, USA (e-mail: phumphrey@partners.org).

TESTUDINES — TURTLES

CHRYSEMYS PICTA (Painted Turtle). USA: MINNESOTA: McLeod Co.: On CR 9 just south of Lester Prairie (44.86563ºN, 94.03034ºW; NAD83). 12 September 2010. Noah J. Anderson, Jeffery B. LeClere, Tessa L. Whitemarsh, and Randy E. Blasus. Verified by Benjamin Lowe. Bell Museum of Natural History (JFBM P362). New county record (Oldfield and Moriarty 1994. Amphibians and Reptiles of Minnesota. University of Minnesota Press, 237 pp.; Gamble and Moriarty 2006. Herpetol. Rev. 37:114–116). Found DOR on road ca. 115 m E of man-made pond surrounded by agricultural fields.

Submitted by **NOAH J. ANDERSON**, Department of Biological Sciences, University of Wisconsin-Baraboo/ Sauk County, 1006 Connie Road, Baraboo, Wisconsin 53913, USA (e-mail: noah.anderson@uwc.edu); **JEFFERY B. LECLERE**, 878 Galtier Street, Saint Paul, Minnesota 55117, USA (e-mail: reptilia74@aol.com); **TESSA L. DEIROCHELYS RETICULARIA RETICULARIA (Eastern Chicken Turtle). USA: MISSISSIPPI: George Co.: Gum pond immediately to the southwest of MS Hwy 57 and Salem Rd. intersection (31.9805167°N, 89.7787667°W; no datum available). 7 July 2008, 0915 h. Will Selman and Thomas Bocek. Verified by Kurt Buhlmann. Florida Museum of Natural History Herpetology Department photographic archive (UF 159536). New county record. This record fills a distributional gap among three surrounding Mississippi counties (Jackson, Stone, Perry) and Mobile Co., Alabama (Mississippi Museum of Natural Science Collections database, http://mdwfp.com/museum/database/bio_collections_online_data.html; Mount 1975. The Reptiles and Amphibians of Alabama. Alabama Agricultural Experiment Station, Auburn, Alabama. 347 pp.; J. Iverson and K. Buhlmann, pers. comm.). Two adults (one female and one male) were observed basking in gum pond on a floating log; two *Pseudemys concinna* (River Cooter) were also observed.

Submitted by **WILL SELMAN**, Rockefeller Refuge, Louisiana Department of Wildlife and Fisheries, 5476 Grand Chenier Hwy, Grand Chenier, Louisiana, 70643, USA (e-mail: wselman@wlf.la.gov); and **THOMAS BOCEK**, Department of Biological Sciences, Box 5018, University of Southern Mississippi, Hattiesburg, Mississippi 39401, USA.

GRAPTEMYS GEOGRAPHICA (Northern Map Turtle). USA: ALABAMA: Jackson Co.: Paint Rock River at Whitaker Nature Conservancy Preserve (34.66450°N, 86.32524°W; no datum available). 25 August 2009. Gregory B. Pauly. Verified by Jim Godwin. Auburn University Museum photographic voucher AHAP-D 267–268. First county record. Adult female (214 mm straightline carapace length, 195 mm straightline plastron length, 1374 g) photographed and released. This species is known to occur elsewhere in the Tennessee River watershed (Mount 1975. Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University. 347 pp.). Tuscaloosa Co.: Blue Creek at Watermelon Road bridge (33.45045°N, 87.41248°W; no datum available). 17 August 09. Gregory B. Pauly. Verified by Jim Godwin. Auburn University Museum photographic voucher AHAP-D 269–271. First county record and the most southwestern record in Alabama. Juvenile (52 mm straightline carapace length, 44 mm straightline plastron length, 25 g) photographed and released. Previously reported from elsewhere in the Black Warrior River watershed. (Mount 1975, *op. cit.*).

Fieldwork carried out under Alabama Conservation License 68-680 issued by the Alabama Department of Conservation and Natural Resources.

Submitted by **GREGORY B. PAULY**, Department of Evolution and Ecology, University of California, Davis, California 95616, USA.

GRAPTEMYS GIBBONSI (Pascagoula Map Turtle). USA: MISSISSIPPI: Lamar Co.: Black Creek, U.S. Highway 11 bridge crossing southwest of Hattiesburg (31.190224°N, 89.376778°W; no datum available). 12 May 2010, 1515 h. Will Selman and Aaron Holbrook. Verified by Peter Lindeman. Florida Museum of Natural History Herpetology Department photographic archive (UF 159527). New county record (Selman and Qualls 2009. Herpetol. Cons. Biol. 4[2]:171–184; P. Lindeman, pers. comm.). Extends known range in Black Creek upstream by ca. 12 river km (Mississippi Museum of Natural Science, specimen #4176 collected near Camp Dantzler, Forrest Co.). A single adult female was observed basking on a deadwood snag 50 m downstream of bridge crossing.

Submitted by **WILL SELMAN,** Rockefeller Refuge, Louisiana Department of Wildlife and Fisheries, 5476 Grand Chenier Hwy, Grand Chenier, Louisiana 70643, USA (e-mail: wselman@wlf.la.gov); and **AARON HOLBROOK**, Department of Biological Sciences, Box 5018, University of Southern Mississippi, Hattiesburg, Mississippi 39401, USA.

GRAPTEMYS OUACHITENSIS OUACHITENSIS (Ouachita Map Turtle). USA: OHIO: Hamilton Co.: Miami Township: Great Miami River at Cleves Community Park. (39.1615°N, 84.7625°W; WGS 84). 18 August 2010. Paul J. Krusling. Verified by Peter V. Lindeman. Cincinnati Museum Center Herpetology Collection (CMC HP 5231, 5232 and 5267 [digital files and prints]). New county record. First confirmed records from the Great Miami River system in over 130 years. These records partially fill a wide gap in the distribution of *Graptemys ouachitensis* in the Ohio River Basin. The closest known extant upstream populations have been documented from the Scioto River, Scioto Co., Ohio, ca. 136 river miles. The closest downstream populations are from Jefferson Co., Kentucky, ca. 112 river miles (Lindeman, *in press*. The Map Turtle and Sawback Atlas: Ecology, Evolution, Distribution, and Conservation of the Genus *Grapte-*

mys. University of Oklahoma Press, Norman).

Submitted by **PAUL J. KRUSLING** (e-mail: pkrusling@gmail.com**), JEFFREY G. DAVIS**, Cincinnati Museum Center- Frederick and Amye Geier Collections and Research Center, 1301 Western Avenue, Cincinnati, Ohio 45203, USA (e-mail: anura@fuse.net); and **RICK LISI**, Audubon Society of Ohio, 3398 West Galbraith Road, Cincinnati, Ohio 45239, USA.

GRAPTEMYS PSEUDOGEOGRAPHICA PSEUDOGEOGRAPHICA (False Map Turtle). USA. OHIO: Hamilton Co.: Miami Township: Great Miami River at Cleves Community Park. (39.1615°N, 84.7625°W; WGS 84). 18 August 2010. Paul J. Krusling. Verified by Peter V. Lindeman. Cincinnati Museum Center Herpetology Collection (CMC HP 5230 [digital files and prints]). The first confirmed record from the state of Ohio. Extends the range ca. 350 river miles upstream from known extant populations in the Wabash River in Indiana. (Lindeman, *in press*. The Map Turtle and Sawback Atlas: Ecology, Evolution, Distribution, and Conservation of the Genus *Graptemys*. University of Oklahoma Press, Norman).

Submitted by **PAUL J. KRUSLING** (e-mail: pkrusling@gmail.com), **JEFFREY G. DAVIS**, Cincinnati Museum Center- Frederick and Amye Geier Collections and Research Center, 1301 Western Avenue, Cincinnati, Ohio 45203, USA (e-mail: anura@fuse.net); and **RICK LISI**, Audubon Society of Ohio, 3398 West Galbraith Road, Cincinnati, Ohio 45239, USA.

KINOSTERNON SUBRUBRUM HIPPOCREPIS (Mississippi Mud Turtle). USA: ARKANSAS: Lincoln Co.: 0.8 km S of Nebo off St. Hwy. 81 at Flat Creek (34.019088°N, 91.814117°W; WGS 84). 6 July 2010. H. W. Robison. Verified by R. Tumlison. Henderson State University Herpetological Collection (HSU 1539). New county records; helps fill a distributional hiatus in southeastern Arkansas between Cleveland and Desha counties (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

Submitted by **CHRIS T. McALLISTER**, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); and **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

PSEUDEMYS CONCINNA (River Cooter). USA: ARKANSAS: Howard Co.: 11.3 km W Umpire at US 278 bridge, Cossatot River (34.295923°N, 94.177680°W; WGS 84). 28 April 2010. H. W. Robison. Verified by R. Tumlison. Henderson State University Herpetological Collection (HSU 1523, photographic voucher, released). Sevier Co.: off US 70 at Red Wing (34.047529°N, 94.237976°W; WGS 84). 4 July 2010. C. T. McAllister. Verified by S. E. Trauth. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 31537, photographic voucher, DOR). New county records (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). Help fill a distributional hiatus in southwestern Arkansas among Little River, Pike, and Polk counties.

Submitted by **CHRIS T. McALLISTER**, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com); and **STAN SPEIGHT**, Cossatot River State Park Natural Area, 1980 Highway 278 West, Wickes, Arkansas 71973, USA (e-mail: Stan.Speight@arkansas.gov).

TERRAPENE NELSONI (Spotted Box Turtle): MÉXICO: CHIHUAHUA: Municipio de Uruachi: Palo Amarillo (27.859594°N, 108.520464°W; NAD 27; elev. 1640 m). 1 July 2006. Paulino Ponce-Campos. Verified by John Iverson. Bosque Tropical photographic collection (BT, M 035a–f). New municipality record and second verified locality in Chihuahua, the first record being located 120 km SE of Palo Amarillo in Arroyo El Camuchil, Batopilas (Lemos-Espinal and Smith 2002. Herpetol. Rev. 32:274.). The closest known locality for this species is from 61 km NNW at Maycoba, Sonora (photographic collection UAZ 55581-PSV). The juvenile reported herein is the smallest (42 mm carapace length) on record for this species and was depicted along with the habitat where it was found (transitional oak woodland and *Acacia* thornscrub) in Franklin and Killpack (2009. The Complete North American Box Turtle. ECO Herp. Publ. Distrib., Rodeo, New Mexico. 242 pp). The locality also appears to be at the highest elevation known for this species. We thank Peter Reinthaler, John M. Legler, and Hans Meijer for details regarding the Maycoba specimen.

SQUAMATA — LIZARDS

ACANTHODACTYLUS CANTORIS (Indian Fringe-fingered Lizard). IRAN: SISTAN & BALOUCHESTAN PROVINCE: Bazman: Mar-abad Valley (27.81451ºN, 60.15781ºE; no datum

available), elev. 970 m. 16 May 2010. Omid Mozaffari and Kamran Kamali. Verified by Muhammad Sharif Khan. Pars Herpetologists Institute (PHIM 00217). First country record, nearest reported locality is Ormara, Pakistan, 550 km to southeast (Minton 1966. Bull. Am. Mus. Nat. Hist. 134:27–184). Two males, one female, and one juvenile found at 1030 h near stream at Valley of Mar-abad; vegetation dominated by *Tamarix* and annual shrubs.

Submitted by **OMID MOZAFFARI,** Pars Herpetologists Institute, Tehran, Iran; e-mail: omozaffari@yahoo.com.

AMEIVA UNDULATA (Rainbow Ameiva). MÉXICO: OAXACA: Municipality of Villa de Tututepéc de Melchor Ocampo: Lagartero (16.050608°N, 97.648250°W; WGS 84), elev. 7 m. 22 December 2007. Aurelio Ramírez-Bautista and Vicente Mata-Silva. Verified by Uriel Hernández-Salinas. Colección Herpetológica del Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo (CIB 2694). First published municipality record that fills a gap between the closest reported localities ca. 250 km E in the vicinity of Tehuantepec, Oaxaca (Hartweg and Oliver 1937. Occas. Pap. Mus. Zool. Univ. Michigan 359:1–8) and ca. 222 km WNW in the vicinity of Barra Vieja, Guerrero (Flores-Villela et al. 1991. Ser. Cat. Mus. Zool. "Alfonso L. Herrera" Cat. [3]:1–222). Casas-Andreu et al. (2004. *In* A. J. Garcia-Mendoza et al. [eds.], Biodiversidad de Oaxaca, pp. 375–390. Inst. Biol. UNAM, Mexico D.F.) reported, without naming specific sites, that this species occurs in floristic-faunistic areas 1, 7, and 9 of the state. The geographic location reported herein is within floristic-faunistic area 8 in the southern coastal region of the state. The lizard was found crawling in leaf litter of tropical deciduous forest ca. 30 m from a marsh

DRYADOSAURA NORDESTINA (NCN). BRAZIL: SERGIPE: Municipality of Itabaiana: National Park Serra de Itabaiana (10.7488ºS, 373447ºW, SAD69; elev. 240 m), 17 January 2009. M. V. Noronha-Oliveira. Herpetological Collection of the Federal Univeristy of Sergipe, Sergipe, Brazil (C240). Verified by D. Oliveira Mesquita. First state record, extending the distribution of *D. nordestina* ca. 250 km from Maceió, Alagoas (Rodrigues et al. 2005. Zool. J. Linn. Soc. 144:543–557). The species is restricted to a few remnants of Atlantic forest of northeastern Brazil, specifically between the states of Rio Grande do Norte and Alagoas (Rodrigues et al., *op. cit.*; Santana et al. 2008. Biotemas 21[1]:75–84; Sales et al. Cuad. Herpetol. 2009 23[2]:77–88), with only one record from the state of Bahia (Guerrero and Rodrigues 2007. Herpetol. Rev. 38:218). However, large distributional gaps remain, indicating the need for additional field surveys.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: GEORGIA: Muscogee Co.: Captured at private residence (2524 52nd Street) within Columbus city limits (32.51487ºN, 84.95584ºW; WGS 84). 26 July 2010. C. McClure. Verified by Craig Guyer. AUM 38918. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.).

Submitted by **CHRISTOPHER J.W. McCLURE** (e-mail: cjm0007@auburn.edu), and **DAVID A. STEEN**, Auburn University Department of Biological Sciences, 331 Funchess Hall, Auburn University, Alabama 36949.USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: Austin Co.: Farm to Market 949 ca. 3.0 km S of Cat Springs, Texas (29.87236°N, 96.84928°W; WGS 84). 11 October 2008. Romey Swanson and Vincent Farallo. Verified by Travis LaDuc. Texas Natural History Collection (TNHC 82802). First county record (Dixon 2000. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press. 421 pp.). Several individuals were observed on window screens at a private farmhouse near Bellville, Texas. A single adult was captured by hand. Measurements were: 11.3 cm total length and 5.2 cm SVL.

Submitted by **ROMEY L. SWANSON** (e-mail: romeyswanson@gmail.com), **VINCENT R. FARALLO**, and **THOMAS R. SIMPSON** (e-mail: r_simpson@txstate.edu), Department of Biology, Texas State University, San Marcos, Texas 78666, USA.

MABUYA AGMOSTICHA. BRAZIL: RIO GRANDE DO

NORTE: Municipality of Santa Maria: Fazenda Tanques (5.854ºS, 35.701ºW; datum WGS84), elev. 137 m. 10 October 2009. J. da Silva Jorge. Coleção Herpetológica do Departamento de Botânica, Ecologia e Zoologia, Universidade Federal do Rio Grande do Norte, Natal, Rio Grande do Norte (CHBEZ 2882, 2883). Verified by M. T. Rodrigues. Species previously known only from three localities: municipalities of Cabaceiras (type locality; Rodrigues 2000. Pap. Avul. Zool. 41 [21]:313–328) and São José dos Cordeiros/Sumé (Reserva Particular do Patrimônio Natural Fazenda Almas), both in the State of Paraíba (Freire et al. 2009. *In* Freire [ed.], Répteis Squamata das Caatingas do Seridó do Rio Grande do Norte e do Cariri da Paraíba: Síntese do Conhecimento Atual e Perspectivas, pp. 51–84. EDUFRN, Brazil) and Xingó in the border between the states of Alagoas and Sergipe (Rodrigues 2003. *In* Leal et al. [eds.], Herpetofauna da Caatinga. pp. 181–236. Ed. Universitária UFPE, Brazil). First state record, extends the distribution ca. 250 km NW from the municipality of Cabaceiras, state of Paraíba, Brazil.

Submitted by **JAQUEIUTO S. JORGE** (e-mail: queilto@yahoo.com.br) and **ELIZA M. X. FREIRE,** Laboratório de Herpetologia, Departamento de Botânica, Ecologia e Zoologia, Centro de Biociências, Universidade Federal do Rio Grande do Norte, Campus Universitário, Lagoa Nova, CEP 59072-970, Natal, Rio Grande do Norte, Brazil (e-mail: elizajuju@ufrnet.br).

LIOLAEMUS GRACILIS (Striped Slender Lizard). ARGENTINA: CHUBUT: Telsen Department: Provincial Route 4, 3.5 km W of Telsen City (42.44106°S, 66.98072°W, WGS84; elev. 432 m). 2 February 2003. L. J. Avila, K. Dittmar, M. Morando, C. H. F. Pérez. Herpetological collection of Centro Nacional Patagónico, Puerto Madryn, Chubut, Argentina (LJAMM-CNP 5486, adult male). Provincial Route 61, 40.3 km from junction with Provincial Route 11, between Ranquilhuao and San Manuel Ranches (42.74689°S, 66.99856°W, WGS84; elev. 117 m). 29 September 2004. L. J. Avila and N. Frutos. (LJAMM-CNP 5947, adult male). Both verified by L. E. Martínez. First department records, extending the known distribution of this species about 160 km W (straight line distance) from the nearest known record (Morando et al. 2007. Mol. Phylogenet. Evol. 43[3]:952–973), representing the westernmost locality for Chubut Province and southwesternmost locality for Argentina. Southernmost citation for this species is the type locality (Puerto Deseado, Santa Cruz Province), but actual collections between Península de Valdés in northeastern Chubut province and the type locality along the Atlantic coast or inland are not known. Present confirmed distribution includes San Luis, Mendoza, La Pampa, southern Buenos Aires, eastern Neuquén, Río Negro, and northeastern Chubut provinces (Avila et al. 2000. Ed. Esp. Asoc. Herpetol. Arg. 5:51–74).

PHELSUMA MADAGASCARIENSIS (= P. GRANDIS) (Madagascar Day Gecko). USA: FLORIDA: Monroe Co.: Saddlebunch Keys, Baypoint, Palm Drive (24.62185°N, 81.59293°W, WGS 84), elev. < 1 m. 15 July 2010. Pam Gimson. Verified by Catherine A. Smith. Florida Museum of Natural History (photographic voucher UF 159376). New island record and eighth known island in the Florida Keys from which this species has been independently introduced (Krysko and Sheehy 2005. Carib. J. Sci. 41:169–172, Krysko and Hooper 2007. Gekko 5:33–38).

Submitted by **KENNETH L. KRYSKO**, Division of Herpetology, Florida Museum of Natural History, Dickinson Hall, University of Florida, Gainesville, Florida 32611, USA; e-mail: kenneyk@flmnh.ufl.edu.

PLESTIODON ANTHRACINUS PLUVIALIS (Southern Coal Skink). USA: MISSISSIPPI: Perry Co.: De Soto National Forest (31.153478°N, 89.012830°W; NAD83). 12 March 2009. James R. Lee. Verified by Robert L. Jones. Mississippi Museum of Natural Sciences (MMNS 16010). New county record (Walley 1998. Cat. Am. Amphib. Rept. 658:1–6 and references therein) that fills the void between Forrest (Smith and List 1955. Am. Midl. Nat. 53:115–125) and Greene (Burt 1937. Trans. Kansas Acad. Sci. 40:349–366) counties, positioned to the west and east, respectively. This specimen and two individuals not collected (all males) were found in a pitcher plant wetland.

Submitted by **JAMES R. LEE**, The Nature Conservancy, Camp Shelby Joint Forces Training Center, CSJFTC-ENV Building 622, Camp Shelby, Mississippi 39407, USA; e-mail: jlee@tnc.org.

PLESTIODON LATICEPS (Broad-headed Skink). USA: WEST VIRGINIA: Berkeley Co.: Sleepy Creek Wildlife Management Area, adjacent to Sleepy Creek Lake (39.531389°N, 78.151111°W; WGS84), elev. 337 m. 20 May 2010. Jeffrey W. Tamplin, Alexa D. Dostart, Derek J. Miller, and Jamie L. Thomas. Verified by Jeffrey Parmelee. Photo vouchers in Drake University Research Collection (DURCPC 135a,b,c). *Plestiodon laticeps* occurs in Fairfax, Loudoun, Prince William, and Warren counties in northern Virginia, and Jefferson Co., West Virginia, but has not previously been recorded from adjacent Berkeley or Morgan counties in the West Virginia eastern panhandle (Mitchell 1994. The Reptiles of Virginia. Smithsonian Institution Press, Washington, DC. 352 pp.; Green and Pauley 1987. Amphibians and Reptiles in West Virginia. University of Pittsburg Press, Pittsburg, Pennsylvania. 241 pp.; T. K. Pauley, pers. comm.). New county record is 25.1 km W of the Jefferson Co. line, and extends the species' range ca. 63.8 km farther N from the Warren Co., Virginia locality, and 81.7 km NW from the closest Loudoun Co., Virginia locality. One adult male and one juvenile *P. laticeps* were captured and released at ca. 1430 h. Habitat was deciduous woodland with a rocky substrate, ca. 1.4 km E of the Berkeley and Morgan county line.

Submitted by **JEFFREY W. TAMPLIN**, **ALEXA D. DOSTART, DEREK J. MILLER,** and **JAMIE L. THOMAS,** Department of Biology, University of Northern Iowa, 1227 W 27th Street, Cedar Falls, Iowa 50614, USA; e-mail: jeff.tamplin@uni.edu.

PODARCIS SICULUS **(**Italian Wall Lizard**).** USA: CALIFORNIA: Los Angeles Co.: San Pedro (33.7169ºN, 118.3022ºW; datum not available). 23 April 2010 and 7 May 2010. Gary Nafis and Guntram Deichsel. Verified by Werner

Mayer. Museum of Natural History in Vienna, Austria (photo voucher and tissue sample; catalogue number: NULA-1). Two additional voucher specimens are deposited at the Natural History Museum of Los Angeles County (LACM 180482–180483). First verified record of *P. s. siculus* from the USA. Burke and Deichsel (2008. *In* Mitchell et al. [eds.], Urban Herpetology, pp. 347–353. Herpetological Conservation Vol. 3. SSAR, Salt Lake City, Utah) present an overview of occurrences of *P. siculus* in the U.S. and mention introduced *P. siculus campestris* only for New York, Pennsylvania, and Kansas. Stebbins (2003. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts. 544 pp.) does not mention *P. siculus* in the area covered in this book.

Werner Mayer analyzed mtDNA from the tissue sample and submitted the result to GenBank (accession number HQ154646). A sequence of 887 bp of the mitochondrial cytochrome b gene differed only by 1% mismatches from respective sequences of *P. s. siculus* from both the city of Agrigento (on the SW coast of Sicily) and from the Monti Peloritani mountains in the northeast of the island. The difference Agrigento–Peloritani is 0.9% mismatches. Sequences from Sicily differ by 1.9–2.4% from sequences from the opposite Italian mainland, i.e., extreme southern Calabria (W. Mayer, pers. comm.).

Approximately 50% of the Californian individuals are of the "concolor" (syn. "olivacea") morph characterized by plain green dorsa. Intergrades with faded, mid-dorsally lined (females) or faded checkered dorsa (males) are also present. Venters are plain white, orange, red, or white with beige spots. This inter-individual variation of coloration is consistent with a Sicilian origin: on the Italian mainland all *P. s. siculus* have plain white venters whereas on Sicily both plain white and colored venters occur (Henle and Klaver 1986. *In* W. Böhme [ed.], Handbuch der Reptilien und Amphibien Europas vol. 3 [Lacertidae III: *Podarcis*], pp. 254–342. Aula Verlag, Wiesbaden).

JH surveyed the area several times after 7 May 2010, confining the occurrence to a ca. 300 m (NW–SE) x 400 m (NE–SW) rectangle centered at South Leland & West 34th streets. We estimate the total population size as over 1,000 animals. By interviewing residents, JH identified the person who originally introduced four females and three males, all adults, from Taormina on Sicily in September 1994. According to this person, "20 male and 24 female adult Southern Italian Wall Lizards, many juveniles, and lots of hatchlings co-exist together with 2–3 Southern Alligator Lizards and 4-5 Western Fence Lizards, all adults" in his/her yard as of 29 June 2010. The total area of the person's lot minus house footprint is 474 m^2, yielding a population density of adult Southern Italian Wall Lizards of roughly one per 10 m^2. In another resident's garden measuring 72 m^2, GD counted nine *Podarcis*, yielding a similar local density. In its home range, *P. s. siculus* can reach much higher densities. We recommend that the expansion of this alien species be monitored and possible interactions with native lizard species should be investigated.

Submitted by **GUNTRAM DEICHSEL**, Friedrich-Ebert-Str. 62, Biberach an der Riss, Germany DE-88400 (e-mail: Guntram.Deichsel@gmx.de); **GARY NAFIS,** PO Box 34628-89546 Seattle, Washington 98124, USA (e-mail: grynaf@yahoo.com); and **JONATHAN HAKIM**, 937 W. 57th Street, Los Angeles, California 90037, USA (e-mail: hakim.ndmva@gmail.com).

PODARCIS SICULUS CAMPESTRIS (Italian Wall Lizard). USA: NEW JERSEY Burlington Co.: Mt. Laurel, 128 Hooton Road (39.9559833ºN, 74.9299944º W; no datum available). September 2008. Russell L. Burke. Verified by D. Kizirian. American Museum of Natural History (AMNH 163007–163019). New county and state record. The closest previously reported populations of this subspecies are Philadelphia (apparently now extirpated [Burke and Deichsel 2008. *In* Mitchell et al. (eds.), Urban Herpetology, pp. 347–353. Herpetological Conservation Vol. 3. SSAR, Salt Lake City, Utah]) and New York City (Burke et al. 2010. Herpetol. Rev. 41:85–86). The population is distributed over a 0.5 km^2 area. An anonymous source claims to have started this population by releasing about 120 *P. siculus* purchased from a Bronx commercial importer/dealer in 1984, and that they were parasitized with mites at the time.

JOHNSON**, Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968, USA (e-mail: jjonhson@utep.edu).

UROSAURUS ORNATUS SYMMETRICUS (Colorado River Tree Lizard). USA: CALIFORNIA: San Bernardino Co.: city of San Bernardino, Kendall neighborhood near NW end of College Avenue, 475 m elev. (34.178879°N, 117.343117°W; WGS84). 26 May 2010. Jonathan Hakim. Natural History Museum of Los Angeles County, LACM 179866. Verified by Neftali Camacho. Introduced population discovered in August 2007 by JB; lizards have continued to be seen in abundance at multiple life stages as of 16 July 2010. Lizards have been observed in an area of ca. 50 acres from Highway 215 northeast to Kendall Drive and from Jasmine Street northwest to the flood control channel that runs parallel to Campus Parkway. The lizards are exclusively found on residential fences and walls in a developed suburban neighborhood. The extent of the population and presence of juvenile lizards suggests the population is established and reproducing. This record is 205 km W of the westernmost native population, in the Corn Spring area on the northeast slope of the Chuckwalla Mts., Riverside Co., California (Stebbins 2003. A Field Guide to Western Reptiles and Amphibians. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 533 pp.). Many of the local homeowners own boats, suggesting that the lizards may have been stowaways from boating trips to Lake Havasu or other nearby areas of the Colorado River where this species naturally occurs, or intentional releases from captures made on such trips.

FARANCIA ABACURA (Red-bellied Mudsnake). USA: GEORGIA: Peach Co.: DOR, State Rt. 49 at Mule Cr. (32.60278ºN; 83.79815ºW; no datum available). 8 May 2010. Digital image AHAP-D 246. First county record. Taylor Co.: DOR, State Rt. 96, 1 km E of Reynolds, at Flint River floodplain (Magnolia Swamp) (32.55267ºN; 84.05382ºW; no datum available). 08 May 2010. Digital image AHAP-D 245. First county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Both specimens collected by S. Graham and verified by Craig Guyer. Decimal degrees of localities were determined using ACME Mapper 2.0 software (http://mapper.acme.com).

Submitted by **SEAN P. GRAHAM,** Auburn University, Department of Biological Sciences, 331 Funchess Hall, Auburn, Alabama 36849, USA; e-mail: grahasp@auburn.edu.

HETERODON PLATIRHINOS (Eastern Hognose Snake). USA: TEXAS: Caldwell Co.: Farm to Market Road 713 near the Caldwell/Bastrop Co. Line Road (29.82858°N, 97.39533°W; WGS 84). 12 April 2008. Romey Swanson. Verified by Travis LaDuc. Texas Natural History Collection (TNHC 82800). A single DOR was collected from the road shoulder. First county record (Dixon 2000. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 421 pp.). The individual measured 48.4 cm SVL and 60.0 cm total length and had a reddish base coloration often seen in specimens collected from Bastrop Co.

Submitted by **ROMEY L. SWANSON** (e-mail: romeyswanson@gmail.com) and **THOMAS R. SIMPSON** (e-mail: r_simpson@txstate.edu), Department of Biology, Texas State University, San Marcos, Texas 78666, USA.

LAMPROPELTIS CALLIGASTER (Mole Kingsnake). USA: GEORGIA: Putnam Co.: Burtom Rd. near Lake Sinclair (33.224543°N, 83.419154°W; WGS84). 18 April 2010. Alfred J. Mead. GCH 5280. Verified by Christopher E. Skelton. First county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Single adult collected DOR on road flanked by mature pine forest and recently established pasture land.

Submitted by **ALFRED J. MEAD** (e-mail: al.mead@gcsu.edu) and **DENNIS PARMLEY**, Department of Biological and Environmental Sciences, Georgia College & State University, Milledgeville, Georgia 31061, USA.

LAMPROPELTIS GETULA (Common Kingsnake). USA: GEORGIA: Wilkes Co.: Tignall, Newtown Road, 1.6 km NW Elam Lunceford Road (33.87554°N, 82.83697°W, WGS84), elev. 163 m. 06 June 2009. Justin T. Oguni and Matthew A. King. Verified by Kenneth L. Krysko. Florida Museum of Natural History (photographic voucher UF 158417). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Found AOR at 2145 h in mixed hardwood forest with residential homes.

Submitted by **JUSTIN T. OGUNI**, College of Veterinary Medicine, University of Georgia, Athens, Georgia 30602, USA; e-mail: goonie16@gmail.com

LAMPROPELTIS GETULA NIGRA (Eastern Black Kingsnake). USA: GEORGIA: Dade Co.: field ca. 100 m NE of jct of Higdon Creek and CR 13, ca. 5.9 air km W of Trenton (34.87262°N, 85.57365°W; NAD83). 17 May 2010. Houston C. Chandler. UF 157836. Verified by John B. Jensen and Kenneth Krysko. First county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Single adult captured and photographed on the bank of a small farm pond. Rural area with mix of forest and pasture and a ca. 5 ha clearcut within sight of capture area.

Submitted by **HOUSTON C. CHANDLER** and **CHRISTOPHER E. SKELTON**, Department of Biological and Environmental Sciences, Georgia College & State University, Milledgeville, Georgia 31061, USA; e-mail: chris.skelton@gcsu.edu.

LEPTOTYPHLOPS HUMILIS (Western Threadsnake). USA: ARIZONA: Mohave Co.: Virgin River valley (36.841538°N, 113.982881°W, NAD 83), elev. 513 m. 24 July 2010. Steven Anderson. Verified by Tom Giermakowski. University of New Mexico Museum of Southwestern Biology (MSB 77882). This is the first record from the Arizona Strip and fills an important gap in the known distribution of the species. Other specimens have been recorded further south, along the lower Colorado River and

from the Grand Canyon, Arizona (Brennan and Holycross 2006. Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix, Arizona. 150 pp.) and to the northeast in Washington Co., Utah (A. Holycross, pers. comm.). NEVADA: Clark Co.: Virgin River Valley, Gold Butte recreation area (36.665935°N, 114.306052°W, NAD 83), elev. 396 m. 22 July 2010. Danny Nielsen. Verified by Andy Holycross. University of Arizona Museum of Natural History (UAZ 57242-PSV, photo voucher). This is the eighth record from southern Nevada and ca. 20 km from nearest known record in Overton, Nevada from 1939 (Grater 1981. Snakes, Lizards and Turtles of the Lake Mead Region. Southwest Parks and Monuments Association, Globe, Arizona. 48 pp.; P. Conrad, Nevada Department of Wildlife, pers. comm.), and ca. 40 km downstream from the Mohave Co., Arizona specimen reported above. Both specimens were collected from pitfall traps in upper riparian habitat of mesquite (*Prosopis* sp. and saltcedar (*Tamarix* sp.).

Collecting permits were issued by the Arizona Game and Fish Department (No. 195230) and Nevada Department of Wildlife (No. S32027).

Submitted by **HEATHER L. BATEMAN** (e-mail: heather.bateman@gmail.com) and **DANNY NIELSEN,** Arizona State University at the Polytechnic Campus, Department of Applied Sciences and Mathematics, 6073 S. Backus Mall, Mesa, Arizona 85212, USA (e-mail: dannynielsen0@gmail.com).

NERODIA ERYTHROGASTER FLAVIGASTER (Yellow-bellied Watersnake). USA: ARKANSAS: Calhoun Co.: DOR ~6 km N of Ouachita River on US 167 (33.392396°N, 92.493676°W; WGS 84). 09 September 2010. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (photo voucher ASUMZ 31555). First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.). The species has also been collected from neighboring Bradley, Ouachita, and Union counties in southern Arkansas.

Submitted by **MATTHEW B. CONNIOR,** Health and Natural Sciences, South Arkansas Community College, 300 S. West Avenue, El Dorado, Arkansas 71730, USA; e-mail: mconnior@southark.edu.

OXYBELIS AENEUS (Mexican Vine Snake). MÉXICO: HIDALGO: Municipality of Tlahuiltepa: Boca de León (20.99139°N, 98.99193°W; WGS84), elev. 464 m. 18 November 2009. Victor D. Vite-Silva, Alejandro Ramírez-Pérez, and Oscar González-Solís. Verified by Norma Manríquez-Morán. Colección Herpetológica, Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo (CIB-UAEH 2538). First record for the municipality, extending the range in Hidalgo ca. 43 km S from the closest known record at La Vega de Metztitlán, Municipality of Metztitlán (Gelover-Alfaro et al. 1999. Rev. Zool. [10]:6–8). The snake was found near a river in tropical deciduous forest.

Fieldwork was funded by CONACyT- 95828.

Submitted by **VICTOR D. VITE-SILVA, ALEJANDRO RAMÍREZ-PÉREZ, OSCAR GONZÁLEZ-SOLÍS, JESÚS M. CASTILLO,** and **IRENE GOYENECHEA**, Centro de Investigaciones Biológicas (CIB), Universidad Autónoma del Estado de Hidalgo, A.P. 1-69 Plaza Juárez, Pachuca, Hidalgo, México; e-mail: ireneg@uaeh.edu.mx.

OXYRHOPUS CLATHRATUS (False Coral Snake). BRAZIL: BAHIA: Municipality of Camacan: Uiraçu Farm, Serra Bonita (15.39405°S, 39.56887°W; Córrego Alegre 24S), elev. 930 m. 26 February 2010. I. Dias, T. Medeiros, and M. Vila Nova. Verified by M. Solé. Museu de Zoologia da Universidade Estadual de Santa Cruz, Ilhéus, Bahia, Brazil (MZUESC 8047). Known from Misiones, Argentina, and southeastern Brazil, from Rio Grande do Sul to Bahia (Argôlo 2001. Herpetol. Rev. 32:61; Peters and Orejas-Miranda 1986. Bull. U.S. Nat. Mus. 297:231). In the state of Bahia the species was known only from Barra do Choça municipality on the Planalto Sulbaiano, a plateau with elevations between 700 and 900 m. The specimen reported here was collected on a mountain ca. 115 km SE, far away and completely isolated from that plateau. The species has never been detected in the low adjacent areas, despite twenty years of intensive study, suggesting that at this latitude the taxon has isolated populations in mountains (Argôlo 2004. As Serpentes dos Cacauais do Sudeste da Bahia, Ilhéus, Editus. 260 pp.; Argôlo 2009. Composição faunística e distribuição geográfica de serpentes na Mata Atlântica do sul da Bahia. Tese de Doutorado, Museu Nacional, Universidade Federal do Rio de Janeiro. 274 pp.). Altough it is a terrestrial species, the specimen was found ca. 2.5 m above ground on vegetation.

Submitted by **TADEU TEIXEIRA MEDEIROS, IURI R. DIAS, MARCOS FERREIRA VILA NOVA,** and **ANTÔNIO JORGE SUZART ARGÔLO,** Universidade Estadual de Santa Cruz, Departamento de Ciências Biológicas, Rodovia Ilhéus-Itabuna, km 16, Salobrinho, CEP 45662-900, Ilhéus, BA, Brazil (e-mail: ajargolo@gmail.com).

PANTHEROPHIS SPILOIDES (Gray Rat Snake). USA: ALABAMA: Henry Co.: County Road 57 NE of Abbeville (31.637933°N, 85.172217°W; WGS84/NAD83). 01 June 2010. R. Birkhead. Verified by Craig Guyer. AUM 38896. New county record. Found dead on road. *Pantherophis spiloides* has been previously documented in all surrounding counties of Alabama, but the related *P. alleghaniensis* has not been documented in adjacent Clay Co., Georgia (Jensen et al.. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.; Mount 1996. The Amphibians and Reptiles of Alabama. University of Alabama Press. xi+347 pp.).

Submitted by **ROGER D. BIRKHEAD**, Alabama Science In Motion, Auburn University, Alabama 36849-5414, USA; e-mail: birkhrd@auburn.edu.

PITUOPHIS CATENIFER SAYI (Bullsnake). USA: WISCONSIN: Pepin Co.: Township of Lima (44.673181°N, 91.871867°W; no datum available.). Verified by Christopher Phillips. Voucher photograph, Illinois Natural History Survey(INHS 2010i). New county record. Fills a gap in the currently known range of this species in Wisconsin (Casper 1996. Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee, Wisconsin. 87 pp.). Several adults were photographed near a possible den location on 26 April 2010, and had been observed in the same general area during the spring of previous years (BB). Old egg remnants encountered near the

individuals photographed in 2010 suggest that this may also be a nesting site for females. The property where the observations were made is an open grassland habitat parcel currently enrolled in the U.S. Department of Agriculture-Farm Service Agency's Conservation Reserve Program. Most adjacent land parcels appear to be dominated by active agriculture. This observation supplements unverified reports from near the township of Durand (Pepin Co.) taken in 2004 and 2008 by Wisconsin Department of Natural Resources employees. It also complements a specimen from adjacent Pierce Co. vouchered in 1988 by J. Moriarty, B. Oldfield, and D. Jones (James Ford Bell Museum 13235), and voucher photographs from adjacent Eau Claire Co. taken by J. Polk in 1988 (Milwaukee Public Museum photograph catalogue number 195-98), and Dunn Co. taken by J. Polk in 1995 (Milwaukee Public Museum photograph catalogue number 561).

Submitted by **BRENT BAUER**, W4292 State Hwy 85, Durand, Wisconsin 54736, USA; **JOSHUA M. KAPFER**, Departments of Environmental Studies and Biology, Elon University, Elon, North Carolina, 27244, USA; **RICHARD A. STAFFEN**, Wisconsin Department of Natural Resources-Bureau of Endangered Resources, 101 S. Webster St., PO Box 7921, Madison, Wisconsin, 53707-7921, USA; and **GARY S. RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). USA: CALIFORNIA: San Diego Co.: City of Chula Vista, Norman Park, 270 F Street (32.64101ºN, 117.07806ºW; NAD 83). 07 November 2006. Marcos Dominguez, Sarmed D. Alzubaidi, and Stanley O'Gara. A second specimen was collected on 28 September 2009 by Daniel D. Palmer, Tony E. Garcia, Trevor H. Jordan. Verified by Jens Vindum. California Academy of Sciences (CAS 244221–244222). This is the first record for California and the west coast of the USA (Kraus 2009. Alien Reptiles and Amphibians: A Scientific Compendium and Analysis. Invading Nature: Springer Series in Invasion Ecology 4. Springer-Verlag. 563 pp.). Apparently reproducing and established given that the first specimen was an adult collected in 2006 and the second specimen collected in 2009 was a small juvenile. Both were found in an urban setting. It is not known if this species will invade native habitats in southern California or presents a risk to native species. Urban Chula Vista is dominated by invasive Argentine Ants (*Linepithema humile*) and it is assumed that this invasive will be abundant prey for the snake.

Submitted by **DANIEL D. PALMER**, Wildlife Research Institute, 18030 Highland Valley Road, Ramona, California 92065, USA; and **ROBERT N. FISHER** U.S. Geological Survey, San Diego Field Station, 4165 Spruance Road, Suite 200, San Diego, California 92101-0812, USA; e-mail: rfisher@usgs.gov.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blindsnake). FEDERATED STATES OF MICRONESIA: KOSRAE: Malem Municipality: 5.302888˚N, 163.028277˚E (WGS 84), elev. 10 m). 22 September 2009. Kenneth R Wood and Wayne Law. Verified by Allen Allison. Bernice P. Bishop Museum (BPBM 36041). New island record for Kosrae. Nearest previous recording ca. 560 km west on Lenger Island, Pohnpei, Federated States of Micronesia (Wallach 2009. Hamadryad 34:34–61). Individual, 65 mm long, collected near house adjacent to swamp forest with associated vegetation of *Horsfieldia irya*, *Neubergia celebica*, *Cocos nucifera*, and *Hibiscus tiliaceus*.

Submitted by **KENNETH R. WOOD**, National Tropical Botanical Garden, 3530 Papalina Road, Kalāheo, Kaua'i, Hawai'i 96741, USA (e-mail: kwood@ntbg.org); and **WAYNE LAW**, The New York Botanical Garden, 2900 Southern Blvd, Bronx, New York 10458, USA (e-mail: wlaw@nybg.org).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blindsnake). HONDURAS: SANTA BÁRBARA: 1 km S of San José de Colinas (15.05°N, 88.30°W; WGS84), elev. 380 m. 30 July 2008. Mario R. Espinal and Leonel Marineros. Verified by Steve W. Gotte. USNM 562754. First record for Honduran mainland and second for Honduras. The only previous Honduran record was from Isla de Utila, Islas de la Bahía (Vesely and Köhler 2009. Herpetol. Rev. 40:116). The snake was found under a rock in leaf litter on a hillside in subhumid forest.

Submitted by **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157–2933, USA (e-mail: jmccrani@bellsouth.net); **MARIO R. ESPINAL**, Centro Zamorano de Biodiversidad, Escuela Agrícola Panamericana, El Zamorano, Honduras (e-mail: mknorops@yahoo.com); and **ADDISON WYNN**, Department of Vertebrate Zoology, National Museum of Natural History, Smithsonian Institution, P.O. RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). KIRIBATI: GILBERT ISLANDS: Tarawa Island: Banreaba Village, South Tarawa (1.3457ºN, 173.0357ºE; WGS 84). July 2009. Ross Craven. AMS R174495. Nabeina Islet: North Tarawa (1.4457ºN, 173.0779ºE; WGS 84). 2007. Ross Craven. AMS R1744496. Verified by R. Sadlier. First confirmed records for Kiribati (Bonin and Shea 2009. Herpetofauna 39:74–77). Only previous record for Kiribati is inclusion of Gilbert Islands in a statement of extralimital distribution in an account of Sumatran snakes, without details, voucher, or bibliographic reference (David and Vogel 1996. The Snakes of Sumatra. An Annotated Checklist and Key with Natural History Notes. Edition Chimaira, Frankfurt am Main. 260 pp.). Nearest records are for Marshall Islands (Knight 1984. Herpetol. Rev. 15:115), and Nauru (Buden 2008. Pacific Sci. 62:499–507).

Found while digging in top 15–30 cm of soil (well drained coral sands with organic matter) adjacent to houses. Dominant vegetation consists of coconut (*Cocos nucifera*), *Guettarda speciosa*, *Morinda citrifolia*, *Pandanus tectorius*, and *Premna serratifolia* in upper and middle stories, with grass *Dactyloctenium aegyptium* at ground level. Other plants present are Breadfruit (*Artocarpus altilis*), Frangipani (*Plumeria obtusa*), *Calophyllum inophyllum*, *Ficus tinctoria*, and *Heliotropum foertherianum*, and several grasses including *Cenchrus echinatus*, *Digitaria setigera*, *Eragrostis amabilis*, *Eleusine indica*, *Lepturus repens*, *Paspalum distichum*, *Stenotaphrum micranthum*, and *Thuarea involuta*.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). MÉXICO: HIDALGO: Municipality of Tasquillo: Tzindeje (20.56394°N, 99.31800°W; WGS84), elev. 1617 m. 12 July 2008. Luis Alberto Trejo Corona. Verified by Adrian Leyte Manrique. Colección de Anfibios y Reptiles del Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo (CIB-2346). First record for Hidalgo, extending its known range ca. 125 km airline NW from the nearest record in Distrito Federal (Mancilla-Moreno and Ramírez-Bautista 1998. Herpetol. Rev. 29:54). The snake was found during the day among fallen logs and sand in thornscrub.

We received support from Diversidad Biológica del Estado de Hidalgo and FOMIX-CONACYT- HIDALGO 43761, 95828, and funding for fieldwork by S52552-Q.

STORERIA OCCIPITOMACULATA (Red-bellied Snake). USA: GEORGIA: Bulloch Co.: 0.5 km S of East Main Street along Willie McTail Trail in Statesboro (32.26604°N, 81.46927°W; datum not available). 26 June 2010. Submitted by Daniel May and Lance McBrayer. Verified by Ray Chandler. Georgia Southern University Herpetology Collection. GSU 9731, 9732. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia 404 pp.). Originally captured on 01 February 2010 and released; then recaptured in the same location (~10 m from creek) under rotten hardwood log covered with kudzu. The gravid female, (GSU 9731; 152 mm SVL, 195 mm TL) gave birth to five offspring in captivity (GSU 9732; mean SVL 57 mm, 75 mm TL). Each animal was photographed and released.

Submitted by **DANIEL MAY** and **LANCE McBRAYER**, Department of Biology, Georgia Southern University, Statesboro, Georgia 30460, USA.

STORERIA OCCIPITOMACULATA OCCIPITOMACULATA (Northern Red-bellied Snake). USA: ARKANSAS: Grant Co.: 1.6 km N of Leola off St. Hwy 46 (34.184684°N, 92.582645°W; WGS 84). 15 June 2005. H. W. Robison. Verified by R. Tumlison. Henderson State University Herpetological Collection (HSU 1556). New county record. Helps fill a distributional hiatus in central Arkansas between Jefferson and Hot Spring counties (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

Submitted by **CHRIS T. McALLISTER**, Science and Mathematics Division, Eastern Oklahoma State College, 2805 NE Lincoln Road, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); and **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

SYMPHOLIS LIPPIENS (Mexican Short-tailed Snake). MEXICO: JALISCO: Municipality of Puerto Vallarta: 1 km W Quimixto (20.50289°N, 105.37747°W; WGS84), elev. 91 m. 29 July 2008. Marko Antonio Guzmán Vargas. Verified by Luis Canseco Márquez. Colección Herpetológica del Museo de Zoología Alfonzo L. Herrera, Facultad de Ciencias, UNAM (MZFCID 03). First record from Puerto Vallarta, which bridges a distributional gap between 16.8 miles (26.88 km) E of San Blas, Nayarit (Zweifel 1959. Am. Mus. Novit. 1949:1–9) and Guadalajara, Jalisco, the type locality for the species (Smith and Taylor 1945. U.S. Nat. Mus. Bull. 187:iv + 1–239). The snake was found in tropical deciduous forest.

Submitted by **IVÁN T. AHUMADA CARRILLO** (e-mail: lepidus320@hotmail.com.) and **MARKO ANTONIO GUZMÁN VARGAS**, Centro Universitario de Ciencias Biológicas y Agropecuarias, Universidad de Guadalajara, Carretera a Nogales Km. 15.5, Las Agujas, Nextipac, Zapopan, Jalisco, México; and **URI OMAR GÁRCIA-VÁZQUEZ**, Laboratorio de Herpetología, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, México, D.F. 04510, México.

TANTILLA OOLITICA (Rim Rock Crowned Snake). USA: FLORIDA: Monroe Co.: Big Pine Key, Ixora Drive (24.6814°N, 81.3519°W; NAD 83). 18 December 2007. Michael A. Yirka, Joseph Flowers, Michael D. Martin, Kevin R. Messenger, and Nathan A. Shepard. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF photograph 152546). Island record. Extends the range 26.7 km west of the closest known locality on Vaca Key (Krysko and Decker 1996. Herpetol. Rev. 27:215). Only known Lower Keys record outside of questionable Key West specimen (Telford 1966. Bull. Florida St. Mus. Biol. Ser. 10:261–304).

Submitted by **MICHAEL A. YIRKA**, 6016 Countryview Ln, Raleigh, North Carolina 27606, USA; **JOSEPH N. FLOWERS**, 4325 Inwood Road, Raleigh, North Carolina 27603, USA; **MICHAEL D. TROPIDOCLONION LINEATUM (Lined Snake). USA: NEW MEXICO: Otero Co.: 1.93 km E of Mayhill on US Hwy 82 and 0.32 km N on Cherry Lane (32.90860°N, 105.46993°W; NAD83/WGS84), elev. 2016 m. 07 July 2006. Ian W. Murray and Christopher Newsom. Verified by J. Tomasz Giermakowski. University

of New Mexico Museum of Southwestern Biology (MSB 72651). New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.). The specimen was found under a small board on moist soil. Other reptile species noted nearby included *Diadophis punctatus*, *Opheodrys vernalis*, *Sceloporus poinsettii*, *S. cowlesi*, and *Phrynosoma hernandesi*. During September 2005 EM found and photographed an adult female *T. lineatum* at this location, but it was not collected.

Submitted by **IAN W. MURRAY**, MSC03 2020, Department of Biology, 1 University of New Mexico, Albuquerque, New Mexico 87131-0001, USA (e-mail: imurray@unm.edu); **ERIK McCORMICK**, 1011 S Yates St., Artesia, New Mexico 88210-2747, USA (e-mail: nmherper@hotmail.com); and **CHRISTOPHER NEWSOM**, 5519 Amistad Rd. GRÜNWALD**, Casa Mexico Real Estate, Ajijic Plaza #1, Ajijic, Jalisco, México (e-mail: cgruenwald@switaki.com).

TROPIDOPHIS GREENWAYI GREENWAYI (Big Ambergris Cay Dwarf Boa). TURKS AND CAICOS ISLANDS: Big Ambergris Cay: N end of island (21.317°N, 71.630°W; WGS84), elev. 3 m. 20 March 2009. J. Burgess, G. Gerber, and G. Reynolds. Verified by J. Iverson. Color photographic voucher, Austin Peay State University (APSU 19018). First published record for Big Ambergris Cay, the type locality, since 1936 and only the third individual ever encountered on the island. Because it had not been found since 1936, despite a great deal of herpetological investigations, the species was thought to have been extirpated from the Island (Iverson 1986. Carib. J. Sci. 22:191–198). The male snake was encountered at night, during a light rain, on a dirt road at the base of a rocky hillside.

Despite of its small size, Panamá is home to 251 species of reptiles, including 89 lizards and 143 snakes (Jaramillo et al. 2010; Köhler 2010; Köhler et al. 2010). The descriptions of new reptiles continue at a steady pace (e.g., Cadle and Myers 2003; Hulebak et al. 2007; Köhler 2010; Köhler et al. 2010, 2007; Köhler and Sunyer 2008; Myers 2003; Poe and Ibañez 2007; Poe et al. 2009; Savage and Watling 2008; Savage et al. 2008), indicating that our knowledge of the Panamanian herpetofauna is still fragmentary and investigative work remains to be done. This applies to taxonomic issues as well as to biogeography. Additionally, the distributions of many species occurring within Panamá are poorly documented. Apart from information scattered among local checklists and publications on single species, only four comprehensive works exist for the country. Pérez-Santos (1999) presented distribution maps with precise collecting localities for 129 snake species. Köhler (2008) provided distribution maps for 238 reptile species occurring in Panamá. Some of the maps pinpoint actual collection sites, but most reflected areas of generalized distribution. The only work considering distribution of the herpetofauna among Panamá's political subdivisions was by Young et al. (1999), therein summarizing the distribution of 228 species at the province level. However, their distributional records were not supported by reference to voucher material, and they did not include the results of two extensive regional inventories by Martínez and Rodriguez (1992) and Martínez et al. (1994). Recently, Jaramillo et al. (2010) summarized the distribution of the Panamanian herpetofauna within physiographic regions and vegetation zones.

During field work on reptiles conducted in western Panamá between May and August 2008, we visited localities within the provinces of Bocas del Toro, Chiriquí, Veraguas, and Comarca Ngöbe-Buglé (a recently established indigenous autonomous region that comprises areas formerly belonging to the other three provinces) (Fig. 1). We collected 217 samples representing 72 species and 17 of those constitute extensions of their known distributions in Panamá. We herein report distribution extensions of

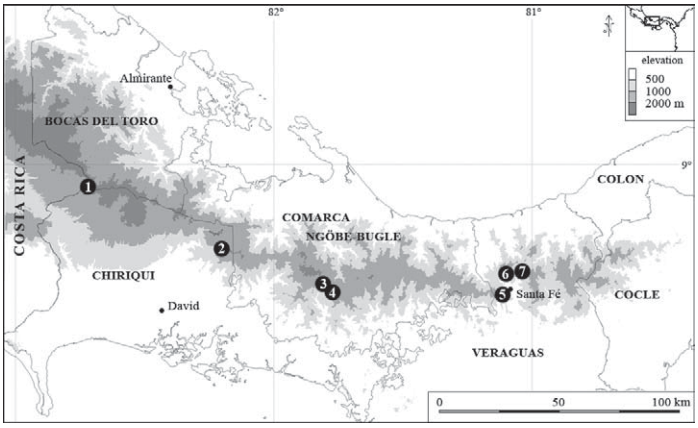

FIG. 1. Generalized localities in western Panamá visited by the authors in 2008: 1) Jurutungo, Chiriquí; 2) Reserva Forestal La Fortuna, Chiriquí; 3) road to Cerro Colorado, Comarca Ngöbe-Buglé; 4) La Nevera, Comarca Ngöbe-Buglé; 5) Cerro Mariposa (= Cerro Tute), Veraguas; 6) Cerro Negro, Veraguas; 7) Río Chilagres, Veraguas.

those 17 species, 11 of which are new provincial records; other accounts list new elevational parameters for the species.

Abbreviations for museum collections follow those of Leviton et al. (1985). Elevations were rounded to the next tenth. The map (Fig. 1) was created using DIVA-GIS and the NASA elevation datasets processed by Jarvis et al. (2006); map datum is WGS84. All vouchers were verified by Javier Sunyer. Common names came from Frank and Ramus (1995), except for *Leposoma southi* (Uetz 2008), *Urotheca guentheri* (Solórzano 2004), and by us herein for *Anolis fortunensis* and *A. pseudopachypus*, two species for which there are no published common names. We decided that for those two species, the common names should denote their type localities; Reserva Forestal La Fortuna, Panamá, and La Nevera, Panamá, respectively.

Squamata — Lizards

Sphaerodactylidae

Lepidoblepharis xanthostigma (Costa Rica Scaly-eyed Gecko). VERAGUAS: Cerro Mariposa, near Alto de Piedra, ca. 3.5 km W of Santa Fé (8.5161°N, 81.1185°W), 880 m elev. 12 May 2008. Andreas Hertz and Sebastian Lotzkat. SMF 89576. Cerro Negro, ca. 6 km NNW of Santa Fé (8.5690°N, 81.0989°W), 700 m elev. 28 July 2008. Andreas Hertz and Sebastian Lotzkat. SMF 89963. Martínez and Rodriguez (1992), in their inventory of "Cerro Tute" (= Cerro Mariposa) and Martínez et al. (1994) in their species list of the nearby mountains, Narices and La Anselma, both reported the presence of *Lepidoblepharis* sp., and considered them to resemble *L. xanthostigma*. However, because the specific identities of these geckos were not made and the respective voucher specimens were lost (V. Martínez pers. comm.), our records represent the first confirmed occurrence for the species in Veraguas. The records also fill the gap between records to the west in Chiriquí and Bocas del Toro and the east in Coclé and Colón (Young et al. 1999).

Gymnophthalmidae

Leposoma southi (Northern Spectacled Lizard). VERAGUAS: Cerro Mariposa, near Alto de Piedra, ca. 3.5 km W of Santa Fé (8.5095°N, 81.1173°W), 900 m elev. 2 August 2008. Leonhard Stadler and Nadim Hamad. SMF 89577. This record extends by 200 m, the upper confirmed elevational limit for the species previously reported by Savage (2002) and Köhler (2008). The presence of *L. southi* around Alto de Piedra was documented by Martínez and Rodriguez (1992). However, elevational distribution for their individual records was unspecified; only a general elevational range of between 800 m and 1450 m was given.

Hoplocercidae

Enyalioides heterolepis (Bocourt's Dwarf Iguana). VERAGUAS: Cerro Negro, ca. 6 km NNW of Santa Fé (8.5690°N, 81.0989°W), 700 m elev. 30 July 2008. Sebastian Lotzkat. SMF 89558. Cerro Negro, 6 km NNW of Santa Fé (8.5693°N, 81.1022°W), 713 m elev. 28 June 2008. Arcadio Carrizo. SMF 89955–56. First records for Veraguas, extending the range more than 50 km W of the formerly westernmost record from El Copé, Coclé (Lips 1999). Köhler (2008) mentioned a record of *E. heterolepis* from Bocas del Toro, which as far as we can tell is not supported by a voucher specimen. A now lost individual from Cerro Narices (between Cerro Negro and Río Chilagres, see Fig. 1) that was listed as *Sceloporus squamosus* by Martínez et al. (1994), actually represented an *E. heterolepis* (A. Rodriguez, pers. comm.).

Polychrotidae

Anolis auratus (Grass Anole). VERAGUAS: road between Santiago and Santa Fé, ca. 8 km N of Santa Fé; (8.1796°N, 80.951°W), 80 m elev. 14 May 2008. Andreas Hertz. SMF 89444. First record for Veraguas, bridging the gap between localities in Chiriquí to the west and Los Santos, Colón, and Panamá to the east (Köhler et al. 2008; Young et al. 1999).

Anolis capito (Bighead Anole). CHIRIQUÍ: Reserva Forestal La Fortuna (8.6744°N, 82.2161°W), 1460 m elev. 16 June 2008. Andreas Hertz. SMF 89449. This record increases the known elevational limit for the species by 160 m (Köhler 2008).

Anolis fortunensis (La Fortuna Anole). CHIRIQUÍ: Reserva Forestal La Fortuna (8.6776°N, 82.1981°W), 1750 m elev. 27 June 2008. Andreas Hertz and Sebastian Lotzkat. SMF 89466. This record extends the known elevational range of the species by 550 m (Köhler 2008).

Anolis humilis (Humble Anole). CHIRIQUÍ: Reserva Forestal La Fortuna (8.6761°N, 82.2006°W), 1660 m elev. 27 June 2008. Sebastian Lotzkat. SMF 89480. This record increases the known elevational range by 60 m (Köhler 2008).

Anolis pseudopachypus (La Nevera Anole). CHIRIQUÍ: Reserva Forestal La Fortuna (8.6761°N, 82.2006°W), 1660 m elev.; (8.6793°N, 82.193°W), 1800 m elev. 25 and 27 June 2008. Andreas Hertz and Sebastian Lotzkat. SMF 89523, 89526, respectively. First records for Chiriquí, and extends the range ca. 50 km WNW of the type locality (La Nevera, Comarca Ngöbe-Buglé; Köhler et al. 2007). COMARCA NGÖBE-BUGLÈ: Valley north of La Nevera, ca. 5.5 km N of Hato Chamí (8.5018°N, 81.7689°W), 1560 m elev. 9 August 2008. Andreas Hertz and Sebastian Lotzkat. SMF 89519–89521. Ridgetop NE of La Nevera, ca. 5.5 km N of Hato Chami (8.4954°N, 81.7673°W), 1810 m elev. 18 August 2008. Andreas Hertz and Sebastian Lotzkat. SMF 89522. These records, near the type locality of *Anolis pseudopachypus*, repre-

sent the lowest and highest elevational records, respectively, for the species, which was previously known only from 1600 m elevation (Köhler et al. 2007).

Anolis salvini (Salvin's Anole). CHIRIQUÍ: Jurutungo, near border with Costa Rica (8.912°N, 82.7182°W), 1980 m elev. 8 July 2008. Andreas Hertz and Sebastian Lotzkat. SMF 89527. This record extends the known elevational distribution of the species upward ca. 150 m (Köhler 2008; Savage 2002).

Anolis vittigerus (Garland Anole). VERAGUAS: Río Chilagres, ca. 9 km NE of Santa Fé (8.5872°N, 81.0363°W), 480 m elev. 3 June 2008. Andreas Hertz and Sebastian Lotzkat. SMF 89528. First record for Veraguas, extending the range ca. 50 km W of the formerly westernmost record from north of El Copé, Coclé (Poe and Ibañez 2007).

Squamata — Snakes

Colubridae

Dipsas articulata (American Snail-eater). VERAGUAS: Cerro Negro, ca. 6 km NNW of Santa Fé (8.5756°N, 81.0976°W), 1000 m elev. 29 July 2008. Arcadio Carrizo. SMF 89552. Since locality data for the holotype of *D. articulata* is imprecise (see remarks in Peters 1960), this is the first validated record for Veraguas. The record reconfirms the species' occurrence at 1000 m, reported as its upper elevational limit by Solórzano (2004).

Dipsas temporalis (Temporal Snail-eater). VERAGUAS: Cerro Mariposa, near Alto de Piedra, ca. 3.5 km W of Santa Fé (8.5107°N, 81.1207°W), 990 m elev. 10 July 2008. Leonhard Stadler and Nadim Hamad. SMF 89552. First record for Veraguas, and a range extension of ca.130 km W of the South slope of Cerro La Campana, the formerly westernmost record in Panamá (Pérez-Santos 1999). Another specimen (SMF 89553) found nearby (8.5245°N, 81.1332°W), 700 m elev., on 5 August 2008 was acquired at the lowest elevation reported for this species (Pérez-Santos 1999).

Imantodes cenchoa (Blunt-headed Tree Snake). COMARCA NGÖBE-BUGLÈ: road to Cerro Colorado west of La Nevera, ca. 10 km NNW of Hato Chamí (8.5303°N, 81.7987°W), 1660 m elev. 10 May 2008. Andreas Hertz. SMF 89573. The locality is situated at an elevation 160 m above that reported for the species by Solórzano (2004).

Oxyrhopus petola (Calico False Coral Snake). VERAGUAS: Río Chilagres, ca. 9 km NE of Santa Fé (8.5872°N, 81.0363°W), 480 m elev. 3 June 2008. Andreas Hertz and Sebastian Lotzkat. SMF 89585. First record for Veraguas, which bridges a distributional gap between localities in the provinces of Chiriquí and Bocas del Toro to the west and Colón and Panamá to the east (Young et al. 1999).

Urotheca guentheri (Striped Glasstail). VERAGUAS: Cerro Mariposa, near Alto de Piedra, ca. 3.5 km W of Santa Fé (8.5002°N, 81.1175°W), 1250 m elev. 5 June 2008. Leonhard Stadler and Nadim Hamad. SMF 89603. First record for Veraguas, filling a gap between localities in the provinces of Bocas del Toro (La Loma, ca.120 km NW) and Coclé (about 110 km E) (Myers 1974).

Viperidae

Bothriechis nigroviridis (Black-speckled Palm Viper). COMARCA NGÖBE-BUGLÈ: La Nevera, ca. 5.5 km N of Hato Chamí (8.4996°N, 81.77°W), 1650 m elev. 11 May 2008. Andreas Hertz, Leonhard Stadler, Nadim Hamad, and Sebastian Lotzkat. SMF 89534. First record for Comarca Ngöbe-Buglé, and an 80 km E range extension from the formerly easternmost record in Boquete, Chiriquí (Dunn 1947).

Bothriechis schlegelii (Eyelash Palm Viper). VERAGUAS: Cerro Mariposa, near Alto de Piedra, approx. 3.5 km W of Santa Fé (8.5157°N, 81.1197°W), 860 m elev. 13 May 2008. Gunther Köhler. SMF 89535. First record for Veraguas, which fills the gap between Isla Escudo de Veraguas, Comarca Ngöbe-Buglé (ca. 85 km NW), and El Valle de Anton, Coclé (ca. 105 km E) (Pérez-Santos 1999).

Acknowledgments.—Collecting and exportation permits SE/A-30-08 and SEX/A-108-08 were provided by A. Salazar, Y. Hidalgo, and J. García, Autoridad Nacional del Ambiente (ANAM), Panamá City, Panamá. Q. D. Fuenmayora and V. Martínez provided valuable assistance with acquisition of permits. An additional permit for the Comarca Ngöbe-Buglé was issued by A. Montezuma (ANAM), San Félix, Panamá. For field assistance and logistical support, we thank C. O'Shea and S. Abrego, A. Bennett, P. Yangüez, O. Cáceres and family, M. Piepenbring, and the Peña Solís family. A. Carrizo received financial support from the DAAD. Field work funding to A. Hertz came from FAZIT-Stiftung and from Studienstiftung des deutschen Volkes to S. Lotzkat.

Only a handful of researchers work on South Asian agamids. Synthetic works on this group are scarce, and a new book on this subject is hence very welcome. It follows a first volume in the Terralog series on South Asian agamids, that included only part of the Draconinae (Manthey 2008), and it aims to list and illustrate the remaining taxa that were not dealt with in that first volume. Taxa newly dealt with are all currently recognized Draconinae belonging to genera starting with the letters G to S (*Gonocephalus*, *Harpesaurus*, *Hypsicalotes*, *Japalura*, *Lophocalotes*, *Lyriocephalus*, *Mantheyus*, *Mictopholis*, *Oriocalotes*, *Otocryptis*, *Phoxophrys*, *Psammophilus*, *Pseudocalotes*, *Pseudocophotis*, *Ptyctolaemus*, *Salea*, and *Sitana*), the Leiolepidinae (*Leiolepis*) and the genus *Physignathus* (whose subfamilial position is still unclear), as well as several undescribed taxa. The book, well bound and with high-quality glossy paper, is bilingual (English-German). It is divided mainly into a table of contents (pp. 3–5), an introduction in which the author gives his point of view on the taxonomic status of various taxa (pp. 6–8), a section on how to use the book, which provides brief advice on captive maintenance (pp. 9–11), literature references (pp. 12–14), and the main section, the species illustrations (pp. 16–168). The front and back covers are finely illustrated and the inner covers provide geographical and political maps of the area covered.

The literature section is short (147 references) and does not provide an exhaustive list of publications on the species concerned, but rather useful references to original descriptions. The most recent references date from 2009.

Color illustrations are provided for each species and represent the strongest point of the book. We counted a total of 524 photographs (not including the nine images on the front and back covers). Twenty-nine of them are biotope photographs. Besides these color photographs, there are four drawings. Only ten species are not illustrated alive, but by drawings or through photographs of preserved type material (clearly indicated as such). All photographs are of very high quality (the whole book is a real delight for the eyes), and many of them, taken *in situ*, provide useful information on biotopes. One of the photographs, showing a *Mantheyus* hatching *in situ*, deserves a special mention. Nearly all of the photographs are accompanied by locality data, which increases their value. Each picture is also associated with a unique coded number, facilitating reference to it, and under each species' pictures, symbols (explained on a folded page) add ecological information. Maps are provided for all species, generally with several species per map. Thirty-three species' geographical distribution maps are distributed throughout the illustrations section. They are not always complete (i.e., some published localities were sometimes omitted), but are generally very good. A very good point is that they include specific dots for the type localities of the species as well as of their synonyms. When for a given species the map is not in direct proximity to the corresponding photograph(s) there is a reference to the map page, which greatly facilitates the use of the book.

One hundred described taxa are included and illustrated, plus eleven populations whose status is unresolved, among them some representing taxa new to science. The most remarkable undescribed taxon photographed is a beautiful green arboreal agamid from Sumatra, provisionally called 'Genus X sp. A'. The others belong to *Gonocephalus*, *Phoxophrys*, *Pseudocalotes*, and *Sitana*. The photographs of these possibly undescribed taxa were smartly included directly near the most similar described species in order to facilitate visual comparisons. Some readers might wonder why the book does not mention *Physignathus lesueurii*, while it has a section on *P. cocincinus*. It is due to the fact that both species were recently shown to be distant and not congeneric, *P. lesueurii* belonging to the *Amphibolorus* group (Hugall et al. 2008).

The book proposes a new generic reallocation '*Pseudocalotes kakhienensis* nov. comb.,' for a species previously included in *Salea*; the rationale for this new placement is briefly mentioned on page 8. Such a reallocation should have deserved a more detailed explanation, but more details can be found in Mahony (2010) who reached the same conclusion in a paper published shortly after the book discussed here. It is to be noted that the monotypic genus *Mictopholis*, recognized as valid by Manthey in the presently reviewed book, is synonymized with *Pseudocalotes* by Mahony (2010). This latter author moreover synonymized *Japalura kaulbacki* with *Calotes kingdonwardi* and transferred it to the genus *Pseudocalotes*. The species had been illustrated under *Calotes k. kingdonwardi* and its synonym *C. kingdonwardi bapoensis* in the first Terralog volume on Draconinae (Manthey, 2008, pages 72–73). '*Pseudocalotes* sp. A' (pp. 144–145) was described as *Pseudocalotes ziegleri* Hallermann, Nguyen, Orlov & Ananjeva, 2010 (Hallermann et al. 2010) just after the book was published. It is a pity that such important changes could not be taken into account in the book.

Several individuals of 'Genus X sp. A' were preserved and currently are under study by one of us (DTI). Unfortunately only females are so far available. The individual in photograph RA02341-4 on page 54, identified as '? *Harpesaurus brooksi*,' is not a *Harpesaurus* (or *Thaumatorhynchus*), but more likely a *Pseudocalotes tympanistriga*; compare with the female of that latter species on photograph RA03696-4 on page 143, showing the very same color pattern. We are unclear as to Manthey's basis for regarding the genus *Thaumatorhynchus* as a synonym of *Harpesaurus*, in spite of striking differences in habitus—roundish body section in *Thaumatorhynchus* versus triangular in *Harpesaurus*, and the absence of dorsal and nuchal crests in *Thaumatorhynchus* versus presence in *Harpesaurus*. The individual in photograph RA02905-4 on page 105, identified by U. Manthey as *Lophocalotes ludekingi*, more likely belongs to the very rare species *Pseudocalotes* (or *Pseudocophotis*) *sumatrana*. The assumption that this latter species has a prehensile tail (see page 7) remains unverified. The '*Leiolepis belliana ocellata*' in photograph RA04712-4 on page 161 is apparently actually a *Leiolepis peguensis* (J. L. Grismer pers. comm. to U. Manthey). This would be good news since that latter species is otherwise illustrated in the book only through a photograph of a faded, preserved paratype of the species. We take the opportunity to mention that the '*Bronchocela* sp. A' illustrated in Manthey (2008, pages 55–56) has since been described as *B. rubrigularis* Hallermann, 2009, and that '*Acanthosaura* cf. *crucigera*' (see Manthey, 2008: 27) was since described as *A. cardamomensis* Wood, Grismer, Grismer, Neang, Chav & Holden, 2010 (see Wood et al. 2010).

Such excellent book quality is no surprise given that the author is already well known for having co-authored a remarkable synthetic opus on Southeast Asian reptiles and amphibians (Manthey and Grossmann 1997), and for his taxonomic studies on agamids (see the literature cited in the volume discussed here). He has described, among other agamid taxa, the enigmatic *Ptyctolaemus phuwuanensis* Manthey & Nabhitabhata, 1991, which was so unique that it was later placed in the distinct genus *Mantheyus* Ananjeva & Stuart, 2001, a name that was coined in recognition of the author's significant herpetological contributions.

The book's price indicated on the Chimaira website, 39.80 Euros (ca. 50 USD) excluding shipping costs, is a bit high, but is largely compensated by the excellent printing and binding quality, and the numerous beautiful photographs. We highly recommend it to all herpetologists and natural history lovers.

We moreover look forward to reading the following opus on agamids in the Terralog series, whose provisionally planned title is 'Agamid Lizards of Africa – Agaminae 1 and Uromastycinae,' by Philipp Wagner and Ulrich Manthey due to appear in 2012 (U. Manthey, pers. comm.). We are very grateful to Ulrich Manthey for kindly answering our numerous questions about his latest book.

Maplewood, Minnesota 55109, USA
e-mail: frogs@umn.edu

The Last Tortoise is the reptilian version of Kathryn Phillips, *Tracking the Vanishing Frogs* (1994). It is a well written book by a non-specialist that covers various aspects of the conservation and survival issues surrounding a group of animals. Stanford travels the world to visit the tortoise hotspots the same way Phillips did at the beginning of the declining amphibian phenomenon, highlighting the work of leading tortoise conservationists at various locations.

The chapters of *The Last Tortoise* cover the decline, conservation and, in some cases, the successes of tortoises across multiple continents. The initial chapters, 'What Exactly Are Tortoises and Turtles' and 'Live Long and Prosper,' provide a good background on tortoise biology and ecology. Descriptions of shell evolution, fossil record, and species diversity are written for the layperson, but provide enough depth for a biologist.

In 'No Respect for the Ancient Lands' Stanford highlights the issues of habitat destruction, human population growth and the impact of invasive and introduced species on tortoises. The results of these activities lead to increased road kill, predation of nests and young, and loss of quality forage. The 'Eating Tortoises' chapter diverges from tortoises and covers the use of freshwater turtles in the food trade, both historic and recent. The author details how the Diamondback Terrapin fishery of the eastern United States lead to the collapse of an abundant species, which is still trying to recover, more than a half century after the end of the commercial harvest. Stanford also covers modern turtle use in China and the impact it is having around the world; although freshwater turtles are mainly at risk, many southeast Asian tortoises are also being consumed.

Many cultures have been keeping and eating tortoises for millennia. Prior to the 20th century population levels of humans were low enough to allow for sustainable use of mainland tortoises. The effect of whalers on island forms are detailed later in the book. The exponential growth of the human population starting in the 20th Century will continue to lead to the extinction of tortoises and other flora and fauna until we can control our population levels.

'Such Huge Deformed Creatures' covers the giant tortoises of the Galapagos and Aldabra. The whaling fleets of the 1800's were able to quickly decimate the populations of these unique tortoises. Several species and subspecies were harvested to extinction. Besides just taking the tortoises the whalers also left rats and goats, which decimated the nests and vegetation. Stanford covers the recovery programs on both island groups to increase and stabilize the populations.

The appendices at the end of the book provide a quick reference to the largest vs. smallest tortoises, the most endangered species and a complete listing of all tortoise species with general distributional information.

The Last Tortoise is a fun and interesting read on the disturbing subject of the potential extinction of tortoises. I would recommend this book to anyone interested in turtles and tortoises. I encourage those of us who are aware of the plight of tortoise to share this book with friends and colleagues who are not. Stanford's engaging writing style will make them advocates for tortoises by the time they are done with the last chapter.

Lizards and Crocodilians of the Southeast, by Whit Gibbons, Judy Greene, and Tony Mills. 2009. University of Georgia Press (www.ugapress.org). Softcover. US $24.95. ISBN 978-0-8203-3158-4.

WALTER E. MESHAKA, JR.

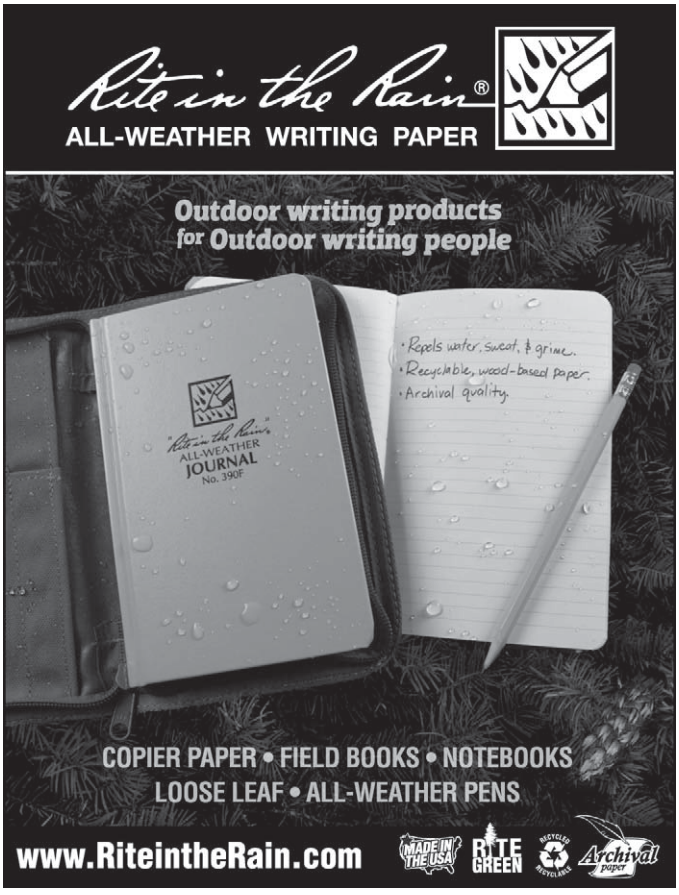
Niche partitioning is readily observable in books focused on regional treatments of amphibians and reptiles. *Lizards and Crocodilians of the Southeast* by Gibbons, Greene, and Mills occupies an underexploited niche, albeit a very important one, being a valuable learning source for beginning naturalists and budding herpetologists. This book also places the southeastern herpetofauna within the larger context of conservation.

The authors initially provide an overview of saurian and crocodilian global diversity, systematics, and taxonomy. Native and exotic species are clearly and concisely juxtaposed with respect to numbers, geographic ranges, and known and potential interspecific interactions. "Did you know?" boxes, which are scattered throughout the book, provide the reader with relevant interesting facts about lizards and crocodilians. Pictures are worth a thousand words, and the numerous photographs are high in quality and effectively illustrate such topics as predation and thermoregulation. I liked looking for the five Green Anoles near their hibernaculum, even though I could only find four of them!

Accounts are provided for each species that will allow a person unfamiliar with a species, such as the Southeastern Five-lined Skink, to identify it as well as learn about its biology. The approach and level of detail are appropriate not only for novices, but also for professionals and serious naturalists inexperienced with the southeastern herpetofauna. Each species account nicely covers various aspects of ecology and concludes with the conservation status of that species. Unfortunately, even some geographically wide-ranging species are no longer abundant and their futures cannot be considered secure.



Distribution maps of both the Southeast and the United States as a whole are useful to the reader and species identifications are facilitated by numerous color photos as well side by side drawings of adults and hatchlings giving body sizes in inches. Accompanying "How do you identify a …" side bars also clearly introduce readers to the most useful and reliable key characteristics for each species.

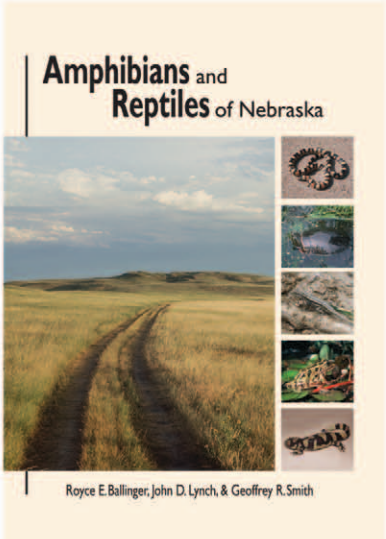
The treatment of the exotic species is slightly different than that of native species. For example, although geographic ranges are discussed, maps are not included because of the dynamic nature of the colonization process. The topics within the exotic species accounts are fewer in light of the information gaps surrounding many of them. The authors have done an excellent job summarizing ecological data and highlighting impacts of the exotic species.

After the species accounts, the authors discuss the "Why" and "How" of studying these reptiles. A section on husbandry follows with a discussion on practical and ethical considerations. With these in mind the authors discuss which species to keep, how to feed and house lizards, and the implications of taking animals from the wild. The last section, "Conservation of Lizards and Crocodilians," concisely encapsulates the theme that permeates the entire book and argues for herpetological education as a means to achieve conservation goals.

Separate tables of the state-by-state occurrence of exotic and native species, a short list of sources for further reading, a glossary, and an index to scientific and common names are all valuable components that round out this work. The "Further Reading" section could have been enhanced by the inclusion of a few quality books on the husbandry of lizards and crocodilians.

Lizards and Crocodilians of the Southeast gets my vote as a useful and inspiring regional source for naturalists from beginners onwards. Its effective integration of perspectives on both conservation and global reptile diversity sets it apart from most other regional reptile guides.

American Museum of Natural History's
Southwestern Research Station
Field Herpetology of the Southwest
24 July – 3 August, 2011



During this 10-day course, participants will gain knowledge on the outstanding biodiversity of amphibians and reptiles found in a wide diversity of habitats throughout southeastern Arizona and parts of southwestern New Mexico.

Participants will obtain hands-on experience in amphibian and reptile identification, collecting and marking techniques, and data documentation. The course also will cover specimen preparation of a full museum voucher specimen, including tissue vouchers and photographs.

For more information about the course contact Dawn Wilson

Amphibians and Reptiles of Nebraska

Royce E. Ballinger, John D. Lynch, and Geoffrey R. Smith

This is a 400 page authoritative review and reference to the 61 species of amphibians and reptiles known to occur within the boundaries of the state of Nebraska. It is the first comprehensive summary of Nebraska's herpetofauna since George Hudson's 1942 book on the same topic which covered the 56 species then known to occur in Nebraska. The book is well illustrated with 251 color photographs and 136 maps and diagrams. Documented with over 970 references, the text provides both an introduction for the amateur and a review for the professional herpetologist. With over 60 years of combined research experience on Nebraska amphibians and reptiles, the authors share many new records, observations, and insights on these fascinating animals.

Price is $45 plus shipping and handling ($5.00), check or money order.

Arizona residents add 8.3% state tax ($3.75)

Order direct from: Rusty Lizard Press, P.O. Box 68058, Oro Valley, Arizona, 85737

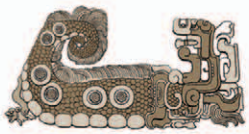
NEW BOOK FROM S.S.A.R.

THE SNAKES OF HONDURAS



by James R. McCranie

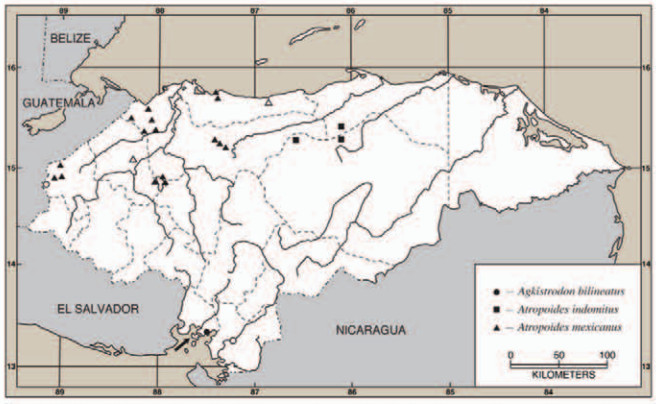
FROM REVIEWS OF THE COMPANION VOLUME, "THE AMPHIBIANS OF HONDURAS," ALSO PUBLISHED BY SSAR:

"An exceptional piece of work, with very high quality text and illustrations . . . the depth and breadth of coverage sets a very high standard." —Gabriela Parra Olea, Mexico City (*Herpetological Review*)

"A model of what should be done to tackle animal conservation problems on a sound foundation." —Jean-Christophe de Massary, Paris (*Alytes*)

"A true advance in our understanding of Mesoamerican amphibians." —Joseph Mendelson, Atlanta (*Copeia*)

HONDURAS IS THE SECOND LARGEST OF the seven Central American countries. Its snake fauna, however, has been one of the least known in the region and numerous studies have referred to the "Honduran hiatus" in distribution and in our understanding of the systematics of indigenous species. James R. McCranie, who began field work in Honduras in 1976, has made an intensive study of the herpetofauna and has now produced a book that will serve to make the snake



fauna of Honduras one of the best known in the world. He has spent a total of more than 1600 days in the field and has personal field experience with nearly every species. He has examined nearly 6200 specimens in researching this book. The result is a model faunal study that will be a welcome reference for scientists and conservationists alike. It will be a reminder of the potential loss of biodiversity in a country in which deforestation and loss of habitat have greatly accelerated over the last two decades. This book is a companion to "The Amphibians of Honduras," by McCranie and Larry David Wilson, also published by SSAR (2002).

The Honduran snake fauna consists of 136 species in nine families: Anomalepididae (1 genus: 1 species), Leptotyphlopidae (1:2), Typhlopidae (2:4), Boidae (2:2), Loxocemidae (1:1), Ungaliophiidae (1:1), Colubridae (50:108), Elapidae (2:6), and Viperidae (7:11). The book has extensively illustrated identification keys in both English and Spanish, a discussion of the Honduran environments, a brief history of reptilian study in Honduras, distribution, and essays about the conservation of the Honduran snake fauna. The bulk of the book consists of detailed accounts of the species (each one includes synonymy, range, diagnosis, description, references to published illustrations, remarks, ecological distribution, natural history, etymology, and specimens examined).

There is a gazetteer of Honduran localities, a glossary, a comprehensive literature cited section, and indexes to authors and taxa. Finally, there are **20 COLOR PLATES** including 22 photographs of habitats and 158 of snakes.

Map 101. Localities for Agkistrodon bilineatus, Atropoides indomitus, *and* Atropoides mexicanus.

Specifications: *about 725 pages, 7 × 10 inches, 112 maps (4 in color), 65 figures, 23 tables, 20 color plates, clothbound. ISBN 978–0–916984–81–6. To be issued February 2011.*

PRICES: **Pre-publication, SSAR members US$80; Institutions, non-members US$95.** ***SHIPPING:*** **USA address, add US$5; non-USA, at cost.**

Send orders to: Breck Bartholomew, SSAR Publications Secretary, P. O. Box 58517, Salt Lake City, Utah 84158–0517, USA (*telephone*: area code 801, 562–2660; *e-mail*: ssar@herplit.com). Make checks payable to "SSAR." Overseas customers may make payment in USA funds using a draft drawn on American banks or by International Money Order. All persons may charge to MasterCard, American Express, Discover Card, or VISA (please provide account number and expiration date). SSAR membership details and a complete list of all Society publications can be obtained on request to the Publications Secretary (address above). For details, check the Society's website at www.ssarherps.org.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints and Page Proofs

Reprints of notes or articles published in ***HR*** may be ordered through EZReprints (EzReprint@odysseypress.com), an online reprint ordering system. Authors will receive email notification as the issue goes to press. Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not sent for natural history notes or geographic distribution notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes. **POSTMASTER:** Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation,* and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available for purchase from the SSAR Bookstore (http://www.ssarbooks.com/). Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 840		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 840	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com. Online orders at: http://www.ssarbooks.com/.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:

http://www.ssarherps.org/pages/membership.php

Future Annual Meetings

2010 — Providence, Rhode Island, 7–12 July (with ASIH, HL)
2011 — Minneapolis, Minnesota, dates TBA (with ASIH, HL)
2012 — Vancouver, British Columbia, dates TBA (with ASIH, HL, WCH)

About Our Cover: *Cnemaspis psychedelica*

The monophyletic Southeast Asian portion of the genus *Cnemaspis* contains 40 species of rock geckos that collectively range throughout much of Southeast Asia west of Wallace's Line. Nearly 70% of the species have been described within the last six years. Rock geckos are largely microhabitat specialists showing high degrees of local endemism, while others are insular endemics. In general, *Cnemaspis* are small, cryptically colored lizards inhabiting primary and old secondary rainforests and generally restrict their movements to the shaded surfaces of rocks, trees, and caves. The combination of cryptic behavior, microhabitat specialization, and morphological conservatism has made it difficult to delimit species boundaries and has generated considerable taxonomic confusion. Until recently, this confluence of circumstances meant that many species went unnoticed as distinct lineages. Current researchers, armed with better knowledge of morphological characters useful in sorting species and a better understanding of where and how to look for rock geckos, have resolved many of these issues. Furthermore, access into previously unexplored territories and unique landscapes has accelerated the rate of new discoveries.

Discovered in 2009, *Cnemaspis psychedelica* is endemic to the small island of Hon Khoai off the southern tip of Vietnam (Grismer et al. 2010. Zootaxa 2352:46–58). This is the most spectacularly colored species in the genus and unlike most other *Cnemaspis*, is diurnal and may even spend time basking. At night, individuals cluster together and take refuge beneath overhangs and within rocky crevices. The reason for their gaudy, seemingly incongruous combination of colors is unknown, but occurs in all age classes and both sexes. Ongoing molecular studies indicate that *C. psychedelica* is the most ancient lineage within Southeast Asian *Cnemaspis* and likely differentiated in a portion of the Sunda Shelf now covered by the South China Sea. Unfortunately, its attractive coloration puts it in the cross-hairs for illegal collection. Fortunately, Hon Khoai Island is occupied exclusively by the Ca Mau Border Army of South Vietnam and non-military personnel are expressly denied access onto the island.

The cover photo by **L. Lee Grismer** was taken *in situ* on Hon Khoai Island at night using a Nikon D300 with an SB 800 Nikon Speed Light and a Nikon VR 105mm macro lens at f.22. **Grismer** is professor of biology at La Sierra University, Riverside, California. He has been working intensively in Peninsular Malaysia since 2003 and in the last six years, his team has added considerably to the region's known herpetofauna. Grismer's latest book, *The Lizards of Peninsular Malaysia, Singapore, and the Adjacent Archipelagos: Their Description, Distribution, and Natural History*, is due to be published in early 2011.

SSAR BUSINESS

SSAR Grants-in-Herpetology Program: Guidelines for Proposal Submission

Proposals are now being accepted for the 2011 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research (particularly conservation biology) on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.
2. FIELD RESEARCH. Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include in-situ behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR, the president of the sponsoring regional society (if applicable), or a student's major advisor or committee chairperson.
3. LABORATORY RESEARCH. Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.
4. HERPETOLOGICAL EDUCATION. Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on a herpetological topic. Proposals must be from individuals only and be accompanied by a letter of support from the herpetological curator, the director of the facility, or the regional society president. Applicants need not be students or a SSAR member.
5. TRAVEL. Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson, or the regional society president.
6. INTERNATIONAL. Proposals may address needs in any of the above five categories. The applicant must be a student, but not necessarily a SSAR member. Preference will be given to students

with limited access to research funds and in countries where herpetological research has historically been under-funded.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be students AND members of the SSAR with the following exceptions: 1) those applying for support of regional herpetological society projects need not be SSAR members; 2) those applying for the International category must be students but need not be SSAR members; 3) those applying for the Herpetological Education category need not be a student or a SSAR member.

Membership dues must be paid (to SSAR Treasurer) no later than 15 December 2010 for proposals to be considered. Applicants are limited to submission of one proposal in one category per year. *Past recipients of an SSAR GIH award in any category are not eligible for future awards*. Applicants must designate to which of the six categories their proposal is submitted (although the committee reserves the right to reassign proposals to categories). If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Detailed guidelines for proposal preparation are available online at:

http://www.ssarherps.org/pages/GIH.php

Successful applicants are encouraged to submit the results of their research for publication in the Journal of Herpetology or Herpetological Review, or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: Joshua M. Kapfer Chair, SSAR Grants in Herpetology, Departments of Environmental Studies & Biology, Elon University Elon, North Carolina 27244, USA. Tel. (336) 278-6229; e-mail jkapfer@elon.edu.

Grants-in-Herpetology Donor Information

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly, and can increase the number and/or size of awards. Your tax-deductible (for U.S. citizens) contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR (kirsten.nicholson@cmich.edu) for additional information about contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

Annual Report (2010)
Grants-in-Herpetology Committee

An award in the amount of US $500 was made to each of the following individuals:

Conservation.—**James C. Cureton II**, Sam Houston State University, "A future without box turtles? Investigating the impact of urbanization on genetic diversity in the threatened Ornate Box Turtle (*Terrapene ornata*)."

Field Research.—**Karla Moeller**, Arizona State University, "Does size matter? Ontogenetic differences in survival strategies of the Gila monster, *Heloderma suspectum*."

Laboratory Research.—**Tara A. Pelletier**, Louisiana State University, "Phylogeographic analysis of *Plethodon dunni* in the Pacific Northwest: postglacial range expansion and contemporary dispersal."

Travel.—**Lindsey Noele Swierk**, Penn State University, "Making the best of a bad situation: Reproductive compensation in mating aggregations of garter snakes in Manitoba, Canada."

International.—**Paulo Fernando Guedes Pereira Montenegro,** Universidade Federal da Paraíba (Brazil), "Water balance in *Pleurodema diplolister* (Peters, 1870) (Anura, Leiuperidae) from semiarid dryland and Atlantic forest in northeastern Brazil."

2010 Grants-in-Herpetology Committee.—Co-chairs: Erik R. Wild and Josh Kapfer. Reviewers: Jeffrey Parmelee, Christopher Beachy, Richard King, Michael Pauers, Steven Price, Bryan Stuart.

SSAR congratulates the 2010 GIH recipients and thanks the committee members for their efforts.

Kennedy Student Award

The Kennedy Award Committee (Bill Lutterschmidt, Mark Paulissen, Terry Schwaner, Lynnette Sievert, Chair) has completed its work for Volume 43 of the *Journal of Herpetology*. The committee has selected "Skin peptide activities against opportunistic bacterial pathogens of the African clawed frog (*Xenopus laevis*) and three *Litoria* frogs" by Ermin Schadich (Vol. 43:173–183). The Kennedy Award carries with it a cash prize of US $200 or the winner's selection of any SSAR publications valued at twice that amount.

The committee invites all student members of the Society to submit their work to the *Journal*, and encourages members who supervise the work of students to draw this award to the attention of those students.

Annual Report (2010)
The Metter Award Committee

There were 24 proposals submitted this year for the Dean E. Metter Memorial Award. The committee requested permission from President Crother and Treasurer Nicholson to make two awards this year in the amount of $750 each and that request was granted.

Matthew Niemiller is a Ph.D. student in the Department of Ecology and Evolutionary Biology at the University of Tennessee in Knoxville. His major professor is Ben Fitzpatrick and his dissertation research deals with the maintenance of distinct cave and surface forms in the plethodontid salamander genus, *Gyrinophilus*.

The second awardee is Michael Reichert, a Ph.D. student in Carl Gerhardt's laboratory at the University of Missouri—Columbia. His research deals with acoustic communication in *Hyla versicolor* and his proposal requested funds to support his investigations into the role of visual cues in the production of courtship calls.

Michael Reichert is the first student from the University of Missouri—Columbia to win a Metter Memorial Award. Dean Metter was a faculty member of the Department of Zoology and then the Division of Biological Sciences at that institution for approximately 30 years.

SSAR congratulates the 2010 Metter Award winners, and extends its appreciation to Metter Award Committee members (Joseph J. Beatty, Chair).

Joint Meeting of Ichthyologists & Herpetologists (JMIH) Official Logo Contest

Concept.—As is well known to all memberships, The Herpetologists' League, American Elasmobranch Society, American Society of Ichthyologists and Herpetologists, and Society for the Study of Amphibians and Reptiles, have embarked on a plan to meet jointly in most years for the foreseeable future. Thus, the Joint Meeting of Ichthyologists and Herpetologists (JMIH) is the official name for this annual meeting of the four societies. The JMIH needs a logo of its own, in part to facilitate a registration website that can be made active before the annual "local logo" may be prepared, and in part to identify the reality of this important ongoing partnership of our societies. Note that this JMIH logo will be a permanent symbol of the JMIH and will not replace the popular annual "local logo" that makes the t-shirts, programs, and other materials of each year's JMIH both memorable and unique. JMIH will hold publishing rights to the logo.

Contest.—The JMIH logo needs to reflect our interests in cartilaginous and bony fishes, amphibians, and reptiles. If you are artistic and would like to submit a logo for consideration, please:

>> Notify Joe Mendelson and submit your logo as a TIFF file by 1 March 2011.

>> Method of voting will be determined by the number of entries. If there are more than five entries, then an on-line voting mechanism will be used to identify the top five entries. This would take place from 15 March to 30 April. All members of all of the societies will be notified of the URL for the on-line voting platform.

>> The five finalist entries will be on display at the 2011 Minneapolis JMIH, where the attendees will have a chance to vote for their favorites, and the winning entry will be selected and announced at the JMIH banquet.

Submissions should be sent electronically (e.g., high resolution TIFF file) to Joe Mendelson: jmendelson@zooatlanta.org.

NEWSNOTES

Control of Disease in Living Amphibian Collections

Infectious diseases have become a well recognized threat to amphibians, both in the wild and in captive collections intended for any purpose including research, teaching, and conservation. With funding from Institute of Museum and Library Services (to San Diego Zoo and Zoo Atlanta) and support from the IUCN Conservation Breeding Specialist Group, a global delegation of amphibian veterinarians, pathologists, biologists, and keepers convened in 2009 to provide input and text for a basic manual on the control diseases in such collections. The manual includes outlines and references to the primary literature regarding recommended best-practices regarding protocols for disease diagnostics and treatment, necropsy, quarantine, routine husbandry, risk assessment, and biosecurity.

The manual is available for download, free of cost, at: http://www.cbsg.org/cbsg/workshopreports/26/amphibian_disease_manual.pdf

Pessier, A.P., and J. R. Mendelson III (Eds.). 2010. A Manual for Control of Infectious Diseases in Amphibian Survival Assurance Colonies and Reintroduction Programs. IUCN/SSC Conservation Breeding Specialist Group, Apple Valley, Minnesota. 229 pp.

Anolis Newsletter VI Available

Anolis afficionados will be pleased that the latest volume of the *Anolis Newsletter* has been issued, assembled by Luke Mahler, Anthony Herrel, and Jonathan Losos. With roughly 400 described species, *Anolis* is the largest amniote genus. Interest in the group has surged in recent years, and the purpose of the *Newsletter* is to provide "an informal forum for the presentation of data and discussion of theory relevant to anoles." The publication may be downloaded as a pdf file at:

http://anolis.oeb.harvard.edu/newsletter.html

David J. Morafka Research Award for 2011

In honor and memory of David J. Morafka, distinguished herpetologist and authority on North American Gopher Tortoises, the Desert Tortoise Council, with the aid of several donors, has established a monetary grant to help support research that contributes to the understanding, management and conservation of tortoises of the genus Gopherus in the southwestern United States and/or Mexico: *G. agassizii*, *G. berlandieri* and/or *G. flavomarginatus*.

Grant Amount.—US $2,000 to be awarded at the Desert Tortoise Council's Annual Symposium, depending on the availability of funding and an appropriate recipient.

Eligibility.—Applicants must be associated with a recognized institution (e.g., university, museum, government agency, non-governmental organization) and may be graduate students, post-

doctoral students or other researchers. They must agree to present a report on the results of the research in which grant funds were used at a future symposium of the Desert Tortoise Council.

Evaluation Criteria.—Applications will be evaluated on the basis of the potential of the research to contribute to the biological knowledge of one or more of the above species of Gopher Tortoises, and to their management and conservation. Important considerations are the significance and originality of the research problem, design of sampling and analysis, preliminary data supporting the feasibility of the research, and the likelihood of successful completion and publication.

The grant announcement, with information on how to apply for it, has been posted on the DTC website at:

http://www.deserttortoise.org/morafkaaward.html

MEETINGS

Call for Papers for the 5th National Symposium on the Ecology, Status, and Conservation of the Diamondback Terrapin 12–14 November 2010, Chauvin, Louisiana, USA

The Diamondback Terrapin Working Group is made up of individuals from academic, scientific, regulatory, and private institutions/organizations working to promote the conservation of the Diamondback Terrapin, the preservation of intact, wild terrapin populations and their associated ecosystems throughout their range. DTWG is committed to and supports research, management, conservation, and education efforts with the above goals in mind. This conference is a forum for the presentation of current information on terrapin research and conservation. In addition to updating colleagues on current research, the conference can serve as a forum to identify research needs, foster friendships, and rekindle interest in terrapins by bringing people with diverse backgrounds together. All interested individuals are invited.

We are accepting abstracts for oral papers and posters from now until 1 October 2010. Posters will be on display on Friday, Saturday, and Sunday morning. The poster session will be on Saturday afternoon. Presentations are planned to be 20 minutes in total length (15 min. presentation, 5 min. questions).

For more information please see www.dtwg.org or contact Dr. Russell Burke, Department of Biology, Hofstra University, 516.463.5521, e-mail: biorlb@hofstra.edu.

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (HerpReview@gmail.com) well in advance of the event.

22–26 September 2010—VIII National Congress of Societas Herpetologica Italica, Abruzzo, Italy. Information: shiabruzzo2010.iscrizioni@gmail.com.

12–14 November 2010—5th National Symposium on the Ecology, Status, and Conservation of the Diamondback Terrapin, at Louisiana University's Marine Consortium (LUMCON) in Chauvin, Louisiana, USA. Hosted by the Diamondback Terrapin Working Group. Information: www.dtwg.org. (see announcement above)

6–7 January 2011—Declining Amphibian Populations Task Force: California / Nevada Working Group annual meeting, Yosemite Valley, Yosemite National Park, California. Information: http://www.canvamphibs.com/News.htm.

18–20 February 2011—36th Annual Symposium of the Desert Tortoise Council, Las Vegas, Nevada, USA. Information: www.deserttortoise.org.

2–7 September 2012—4th International Zoological Congress (IZC), Mount Carmel Campus, University of Haifa, Haifa, Israel. To receive the first and subsequent meeting announcements, contact the organizers at: izc2012@sci.haifa.ac.il.

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Joshua Hale or Ben Lowe; postal and e-mail addresses may be found on the inside front cover.

A listing of current contents of various herpetological journals and other publications is available online. Go to: http://www.herplit.com and click on "Current Herpetological Contents."

Squamates Also Susceptible to Effects of Climate Change

The potential impacts of climate change on amphibians have been well studied and are widely appreciated; however, little attention has been paid to the possible effects on squamates. In this paper, using 35 years of data, the authors investigated distributional and population changes in 48 species of Mexican *Sceloporus* (Phrynosomatidae). Two hundred sites for which species composition had been assessed between 1975 and 1995 were recently resurveyed. Additionally, climate data from 99 Mexican weather stations was accumulated and used to generate a climate model for the country. Using these data, the authors found a strong correlation between the degree to which spring temperatures have increased and population extirpation. Furthermore, multivariate statistical methods taking into account phylogenetic relationships revealed that species inhabiting narrow elevational and/or latitudinal bands exhibited increased incidence of extirpation, as did viviparous species. Using physiological models derived from studies of *Sceloporus serrifer* on the Yucatán peninsula, they determined that a four hour reduction in time wherein temperatures are suitable for activity was sufficient to cause a local extirpation. When extrapolated across Mexico, this reduction of suitable activity period during the breeding season

proved to be an accurate predictor of population extirpation. Given the low heritability of optimal body temperature and the rate at which the climate has and will change, lizard species are generally incapable of evolving fast enough to adapt to their changing environments. Indeed, these authors contend that 56% and 46% of populations of viviparous and oviparous Mexican *Sceloporus* (respectively) will be extirpated by 2050. Species extinctions will be almost as high, as highly endemic species are disproportionately susceptible to the effects of climate change. If extrapolated to a global scale, these findings suggest that upwards of 20% of the world's lizard species may be extinct by 2080. Hopefully these findings will lead to increased awareness of squamate declines in the herpetological and conservation communities.

First Documentation of Tadpole Vocalization

Although vocalization in adult anurans is well documented, no records of tadpole vocalization exist. While conducting frog research in Argentina, the authors of this paper made the first observations of tadpole vocalization in the species *Ceratophrys ornata* (Ceratophryidae). These calls consist of metallic clicks and are produced via the expulsion of air from rudimentary lungs through the glottis. Tadpoles of this species are capable of vocalizations as early as 72 hours after hatching despite the lack of laryngeal cartilages. Vocalizations are accompanied by lateral undulations of the tail and are made both under and out of water (out of water vocalizations are more vigorous, presumably due to the availability of air). Tadpoles were only observed to make these calls when threatened with intraspecific predation or touched with an object such as a pipette. Therefore the investigators concluded that vocalizations fall under the category of "distress call"; indeed, they are remarkably similar to distress calls made by froglets and adults. Furthermore, the authors propose that these vocalizations aid in preventing cannibalism (as larvae of this species primarily predate other tadpoles). In support of this hypothesis, the authors report that, contrary to previous reports regarding this species, tadpoles maintained together in captivity in low densities (~5 larvae/L) were never observed to engage in cannibalism while feeding entirely on heterospecific tadpoles. Finally, the presence of lungs, glottis, and associated musculature in many other larval anurans suggests that this phenomenon may be more widespread than currently recognized.

Rate of New Reptile Species Descriptions at All-Time High

Using the Reptile Database supported by the Institute for Genomic Research (http://www.reptile-database.org), the author of this paper compiled and/or calculated a number of interesting findings pertaining to the description of reptile species. As of September 2009, the database recognized 9084 species of reptile. As the managers of this database take a conservative approach to species recognition (essentially a Biological Species Concept), many would view their totals as significant underestimates. Forty biologists are responsible for the description of more than half of all described reptile species (each having described 50 or more species; eight are alive today). Leading this elite group is George A. Boulenger, who single-handedly described 573 currently-recognized species. A graph plotting annual number of species descriptions over time reveals that the second half of the 1800s witnessed a surge in species descriptions; at the peak of this period, as many as 70 species were being described per year. Since a low of twenty species on average being described per year in 1950, a comparable trend has been occurring; we are currently in the midst of this spike in species descriptions, with an average of 90 species a year being described (and the trend shows no sign of leveling off). This paper provides tables listing and describing the journals containing the most reptile species descriptions and works containing descriptions of more than twenty species; it also provides resources for tracking down hard-to-find publications containing reptile species descriptions.

New Monitor Lizard Discovered in the Philippines

Even in the 21st century, unknown reptile and amphibian species remain to be discovered. Researchers conducting fieldwork in the Philippines have recently brought to light a species of monitor lizard (Varanidae) wholly new to science. Described as *Varanus bitatawa* (the specific epithet is derived from a local name for the animal), this species is a montane endemic of the eastern mountains of northern Luzon Island. Despite having gone unnoticed by science, local people have long exploited this species as a source of protein. Phylogenetic analyses reveal that this species is closely related to an ecologically similar species endemic to southern Luzon Island, *V. olivaceus*. The two species are separated by unforested, low-elevation valleys in the central portion of the island. As this geographic feature appears to have contributed to phylogeographic structuring in other taxa as well, it appears these low valleys constitute an important biogeographic feature for the region. While both species are arboreal and frugivorous, *V. bitatawa* can be distinguished from the drab *V. olivaceus* by its distinctive bands of golden spots (akin to those of the perentie, *V. giganteus*) and unique hemipenal morphology. Based on morphology, the authors showed that these species are allied with a third enigmatic, arboreal, frugivorous monitor

endemic to the Philippine island of Panay (*V. mabitang*); together these three species comprise a clade endemic to the Philippines and only distantly related to other *Varanus* species. Given the degree to which the forest habitat has been altered, this discovery heightens the need for conservation efforts focused on protecting the unique fauna and flora of Luzon Island.

Evolution of Range-Expansion Phenotype Preceded Toads Colonizing the World

Members of the family Bufonidae represent an evolutionary success story. Indeed, recent studies suggest toads colonized North America, Europe, Asia, Africa, and secondarily colonized South America over the span of a mere 10 million years (essentially the Eocene). The authors of this paper set out to discover how toads managed to colonize and subsequently diversify throughout four continents in such a short period of time. Suspecting that the dispersal success of toads may be tied to the large geographic distributions exhibited by many species (as large contemporary distributions are indicative of past range expansion events), the authors collected morphological and life history data on 228 species (~43% of described species) and performed analyses (accounting for phylogenetic relationships) aimed at detecting correlations between character states and distribution size. Five character states were found to be strongly correlated with large distributions: semiterrestrial adult niche, the presence of parotoid glands and inguinal fat bodies, broad range of suitable aquatic conditions for oviposition, and reduced maternal yolk contribution. Interestingly, this "range-expansion phenotype" bears a striking similarity to the archetypal toad phenotype. Using published sequences of two nuclear and nine mitochondrial genes and six calibration points, the authors performed phylogenetic analyses and recovered divergence dates for the family Bufonidae. Subsequently, an ancestral character state reconstruction analysis was performed resulting in the ancestral states for the characters found to be correlated with large geographic distribution being mapped onto the time-calibrated phylogeny. These analyses recovered a more recent global colonization date than previous studies (Oligocene) and revealed that the bufonid age of colonization was preceded by an abrupt shift toward the archetypal toad phenotype. Interestingly, upon colonization of new continents, several lineages independently shifted away from the toad phenotype. This study reveals that the evolution of a range-expansion phenotype facilitated rapid diversification and colonization in bufonids. This novel mechanism stands in stark contrast to the typical path to rapid diversification: limitations to dispersal that promote fragmentation and subsequent allopatric speciation. Furthermore, this idea of a range-expansion phenotype provides an evolutionary explanation as to why *Bufo marinus* (= *Rhinella marina*) has been such a successful invasive species around the world.

Competition Found to be Important Driver of Natural Selection in *Anolis*

Despite much speculation regarding the relative contributions of predation and intraspecific competition toward natural selection, few field-based experiments have been carried out with the goal of teasing these two factors apart. The authors of this paper conducted an experiment with this aim using anoles (Polychrotidae: *Anolis sagrei*) on experimentally manipulated islands off the shore of the Bahamas. Lizards were measured for traits presumed to be under strong selection (body length, relative hindlimb length, and treadmill performance), marked, released onto islands in the spring, and recaptured in the fall. These islands were populated with varying densities of lizards (0.09–0.3 lizards/m^2) and either excluded from predators (via netting), exposed to avian predators only, or exposed to avian predators and seeded with ophidian predators (Xenodontinae: *Alsophis vudii*). While exposure to predators was found in regression analyses to affect survivorship and behavior (lizards in treatments with snakes exhibited significantly lower survivorship and perched higher than lizards in either of the other predation treatments), predation exposure treatment was not found to be a significant predictor of change in the measured characters. However, these analyses found lizard density to be strongly correlated with significant changes in these characters, with survivors on high-density islands exhibiting higher average values for the characters measured than at the start of the experiment (and survivors on low density islands exhibiting lower average values than at the start of the experiment). The authors conclude that while predators likely contribute to natural selection in *Anolis*, these effects are trivial relative to the effects contributed by intraspecific competition. Furthermore, these findings suggest that competition may have had a larger role in shaping *Anolis* morphological and species diversity than currently appreciated.

First Documented Case of Non-hybrid Origin of Unisexuality in Vertebrates

Parthenogenetic squamate lineages have originated independently several times and all known instances have been hypothesized to have occurred via hybridization events between two sexually reproducing species. The authors of this paper present results that reveal the first conclusive evidence for populations of parthenogenetic squamates (indeed, vertebrates) originating through pathways other than interspecific hybridization. Nuclear (nDNA; 8 loci) and mitochondrial (mtDNA; 2 genes) sequence data and microsatellite marker (14 loci) genotypic data were assembled for two parthenogenetic populations of tropical night lizards (*Lepidophyma*; Xantusiidae) in Costa Rica and Panama as well as geographically proximate congeners. Sequence marker data were analyzed for allelic variation, interlocus congruence, and phylogenetic relationships; microsatellite marker data were analyzed for heterozygosity and linkage disequilibrium (it has been hypothesized that heterozygosity in unisexual lineages might degrade over time to resemble homozygosity [the "Asher Effect"]; however this phenomenon would leave the various loci in linkage disequilibrium, as the fixed loci would be randomly drawn from each of the parental species). Parthenogenetic populations of one species (*L. flavimaculatum*) were found to be genetically indistinguishable from conspecific sexually reproducing populations to the north for each sequence marker examined and the species was recovered as a well-supported clade (sister to *L. reticulatum*, the other parthenogenetic species) in phylogenetic analyses of both mt- and nDNA. Additionally, while sexual *L. flavimaculatum* exhibited moderate levels of heterozygosity, both unisexual populations showed little mtDNA heterozygosity and were fixed for all microsattelite loci (which were not in linkage disequilibrium) and most nDNA loci. These results strongly refute a hybrid origin for these parthenogenetic populations of *Lepidophyma*. Whether unisexuality evolved twice, was secondarily lost in sexual populations of *L. flavimaculatum*, or represents an ancestral polymorphism that has reached fixation in *L. reticulatum* remains unknown.

Dynamics of Sexual Dimorphism Revealed in Hynobiid Salamanders

Sexual size dimorphism can occur when different selection pressures are experienced by each sex. Whether or not sexual size dimorphism is evident prior to sexual maturity reveals which life stages selection is acting upon. To elucidate the patterns of development of the two sexes, the author of this paper collected data on salamanders (Hynobiidae: *Salamandrella keyserlingii*) in a marsh in Hokkaido Prefecture, Japan. Over the course of three years, animals were captured, measured for various morphological characteristics, marked via toe clipping, and released on site. Collecting events coincided with both the aquatic, reproductive phase (April–May; both pitfall traps and dip netting) and the terrestrial, non-breeding phase (late May–October; pitfall traps only). Toe clips were retained for lines of arrested growth (LAG) analyses to estimate animal ages. These data revealed that prior to sexual maturity both sexes grow at a similar rate and after maturity both experience similar declines in growth rate; however, females mature roughly a year later than males, leading to a larger size at maturity and larger size relative to age after the age of male maturity. The selective advantage of larger female size is presumably the prospect for greater clutch size (although non-adaptive explanations also exist). Interestingly, males seem to compensate for the sexual size dimorphism via secondary sexual characteristics developed prior to and lost after the aquatic breeding phase. Specifically, males develop widened heads (used in male-male combat) and elongated tails (used for detaining females) and in general achieve the size of reproductively mature females. The author posits that this temporary male sexual dimorphism may be a requirement for the development of permanent female sexual dimorphism, as the evolution of larger females requires males to have the ability to temporarily achieve similar size for successful reproduction.

Comparisons Between Squamate Lineages Reveal Insights into Locomotion and Body Plan Evolution

Is it possible for lineages with morphologically dissimilar ancestors that are evolving in divergent morphological directions to converge on similar locomotor strategies? To address this question, the authors of this paper examined members of two disparate lineages (phrynosomatid lizards in the southwestern US and *Lerista* [Scincidae] in Western Australia), some members of which have evolved highly apomorphic body plans (stocky and elongate bodies, respectively) relative to their more classically proportioned ancestors. Species were scored for a variety of morphological metrics, including body width and hind limb length (both relative to body length). Subsequently, animals were subjected to filmed locomotor trials on both sandpaper and sand substrates to characterize their kinematic strategy (e.g., stride length) and locomotor performance (e.g., speed). Comparisons with ancestors revealed that stockiness was achieved solely through trunk widening (with no shortening) and elongation was attained via trunk elongation alone (no contribution from torso narrowing). Furthermore, despite widely divergent morphologies, stocky and elongate species examined exhibited locomotor similarities with each other and not shared with their ancestors. Specifically, they demonstrated similar stride length and reduced speed. However, differences between these two groups were also observed; stocky phrynosomatids had lower stride rates (due

to wide body and robust limbs) and elongate *Lerista* achieved faster speeds (due to contribution from elongate axis). Finally, substrate type had no effect on locomotor performance for any species examined, suggesting that both clades consist of substrate generalists and the derived morphological conditions are not adaptations to a particular substrate.

Some Turtles Exhibit Reduced Metabolic Rates upon Hatching

Due to different costs and benefits, embryonic and post-embryonic animals might exhibit different metabolic rates. For example, due to the availability of yolk and the advantage of rapid development, embryonic reptiles should display an increased metabolic rate relative to hatchlings, which often lack a dependable food source. Yet, results of previous investigations of reptiles have been conflicting, with squamates displaying no change in metabolic rate and birds showing an increase (likely due to the switch to endothermy). To investigate this phenomenon in Testudines, the authors of this paper examined embryonic and post-embryonic metabolic rate (using heart rate as an indicator) in two species of emydid turtle (*Chrysemys picta* and *Graptemys pseudogeographica*) across a range of temperatures. Interestingly, at low temperatures (20–25ºC), no change in metabolic rate was observed, yet at high temperatures (30–33.5ºC) a significant decrease upon hatching was seen. The authors conclude that a change in selective pressure between embryonic and post-embryonic life stages is responsible for this change in metabolic rate. In particular, they point to the benefit of increased embryonic development via increased metabolic activity at high temperatures which they posit has been under strong selection in turtles. Alternatively, shorter-lived squamates have adopted a riskier strategy (given the uncertainty of food resources) of maintaining high metabolic rates into juvenile and adult life stages.

Insights into the Evolution and Function of Snake Thermoreception

Boas, pythons, and pit vipers possess pit organs which allow them to sense heat emitted from potential prey and predators. Though much has been learned about the capabilities and limitations of these structures, remarkably little is known about how they sense heat and the evolution of ophidian thermoreception. The authors of this study used molecular techniques to divulge the particular mechanisms involved in serpent thermoreception. By investigating translated RNA fragments ("transcriptomes") recovered from the trigeminal nerve (the nerve that receives general sensory information from the face, including the pit structures) and nerves associated with dorsal root ganglia (nerves that receive sensory information the somatic region of the body), they were able to identify a single gene (*TRPA1*) coding for a protein (TRPA1) associated with a particular receptor. This was possible because in non-thermoreception-capable animals such as mammals, the two nerve types exhibit similar transcriptome profiles and therefore differences observed in thermosensory-capable snakes should reflect genes affiliated with thermoreception. Interestingly, the homologous receptor in humans has been dubbed the "wasabi receptor," as it has been found to be sensitive to the Japanese condiment. Furthermore, this finding confirmed the suspicion that thermoreception in snakes involves detection of a change in temperature of the membrane lining the pit (akin to standard epithelial thermoreceptors) rather than a direct reception of photons (akin to optic photoreceptors). Finally, a phylogenetic analysis of the *TRPA1* gene revealed that pit vipers and other thermoreception-capable snakes derived their heightened TRPA1 gene expression independently, as pit viper *TRPA1* is more closely related to phylogenetically proximate but thermoreception-incapable colubrid *TRPA1* than to boid or pythonid *TRPA1*.

Dana Payne in the Columbia Gorge area in Washington State doing field work with the Western Pond Turtle (*Actinemys marmorata*). He is holding an adult female (note transmitter attached) that was part of a study to locate nesting areas.

Dana Payne, Curator of Reptiles at the Woodland Park Zoo in Seattle, lost his long-term battle with cancer on 20 March 2010. Dana was well respected in the herpetological zoo community where he was known for his comprehensive knowledge of the natural history of reptiles and amphibians, his dedication to the zoo field, and the conservation of herps around the world.

Dana was born in San Diego, California on 26 August 1955 and moved to the Seattle area when he was very young. He was the oldest of a family of seven children and developed a keen interest in animals—especially reptiles—early in life. His mother would often take him to the zoo and on each trip he learned new facts about the animals. This set the stage for Dana's long career in the zoo profession. He first began volunteering in 1974 at the Reptile House at Woodland Park Zoo. He received his first professional job as a reptile keeper at the Chaffee Zoo in Fresno (California), working with and being mentored by Curator Ron Tremper. In 1982 he returned to Woodland Park where he spent most of the next 15 years working in the Day House specializing in reptiles and amphibians. In 1997, he was promoted to Senior Keeper, then to Collection Manager, and finally to Reptile Curator in 2003, a position he held until his death.

Conservation was one of Dana's passions. He became involved with the El Valle Amphibian Conservation Center in Panama. Because of his fluency in Spanish, Dana worked to develop a Spanish-language record-keeping system, and also consulted on matters of husbandry and *in situ* breeding projects. At home in Seattle, Dana was the steward of Woodland Park's role in the Western Pond Turtle recovery program for many years. He worked alongside the Washington State Department of Fish and Wildlife overseeing the headstarting of turtles at the zoo. A more recent effort was Dana's leadership role in the conservation of the Oregon Spotted Frog, facilitating a consortium of Pacific Northwest institutions.

During Dana's time as a Reptile Curator, he was instrumental in forming a team that developed an online Antivenin Index Database. Dana brought forth the idea of a website where institutions could post their inventories of exotic types of antivenins. Poison control centers and zoos could consult this index to obtain antivenin in the case of an emergency snakebite. This could save lives by reducing the amount of time needed to locate the proper antivenin and have it shipped quickly to the treating hospital. Dana was very knowledgeable on venomous snakebites and was consulted by regional hospitals as well as providing informational tours of the zoo's venomous reptiles to local physicians.

Dana's accomplishments were not restricted to the field of herpetology. Dana had a keen interest in computers and programming. He designed several database programs that are being used not only at Woodland Park but other zoos around the globe. They were implemented for many types of record keeping and tracking of animals in collections. Dana's computing skills were so impressive and valuable to zoos that he received an award for outstanding application design.

Dana's life was centered on his enthusiasm for the zoo and the animals around the world. When he was asked what he liked best about working at a zoo, he said "It's really all about helping people to care about the natural world we're working to save." Dana was asked to write the end note in a book of animal prints by telling a story of relations between people and animals. This is what he wrote. "Those of us who have chosen a life with animals know we have chosen well. Having a conversation with a lion is a fine way to start one's day. For that matter, so is tossing tidbits to a toucan, or medicating a cobra. There's something there, in the lion's luminous eyes, in the gaudy splendor of the toucan, in the cobra's sibilant protests: it's *magic*. It's the stuff of fairy tales to interact with animals like these, even in a scientific setting, and in spite of repetitious, routine chores. You should envy us, for we are the most fortunate of humans—we take care of the animals at the ZOO."

Dana's personality left a lasting impression. He was a witty, kind, and generous friend and colleague who didn't deserve all the setbacks that life dealt him. After losing a foot in a motorcycle accident, along with all the pain and hassles of having one leg, sometimes on crutches, sometimes with his prosthesis, sometimes not being able to walk at all, he rarely complained. It was just the luck of the draw he said. After he was diagnosed with cancer and undergoing treatment, as he was contemplating his demise he looked at FS, laughed and said "Look… nobody gets out alive."

Dana will be remembered for his knowledge and devotion to herpetology and the zoo world. We can still clearly see his smile and hear his bold laugh. He will be missed by many, truly a hard act to follow.

Acknowledgments.—We thank Ron Tremper for sharing recollections.

As wholesale animal dealers and stores joined in the development of the modern pet business, they supported a more aggressive search for other animal novelties and "seasonal merchandise" in animals. Novelties were often creatures that never would have been indoor pets–or pets at all–in the nineteenth century. By the 1920s, the Max Geisler Company of Omaha had added to its stock American chameleons (*Anolis* lizards), which became a staple of childhood terrariums after World War II and were sold at circuses wearing little wire collars and leashes, at least through the mid-1960s. In 1928, the National Pet Shops of St. Louis, Missouri, offered to ship "TEXAS HORNED FROGS...Alive and Attractive...25¢ each/$1.50 Dozen - $4.50 for 50. Eight Dollars per hundred." As pet shops joined the quest for novelties to attract new customers, animals often faced unpleasant consequences. Seasonal and novelty pets had little prospect of long or healthy lives. Easter chicks, dyed like eggs, were too fragile to survive the rough handling of small children. The needs of reptiles also were too specialized for the casual purchaser; they, too, became throwaways. According to recent surveys, Americans now care for millions of reptiles as pets. As with most aquariums, reptiles as pets are often associated with the presence of children in the house, but a community of serious amateurs thrives; they can be described as "collectors" as much as pet owners. They sponsor special pet shows and sales and are engaged in serious breeding efforts to create genetic sports. (A trip to one of their shows is an astonishing experience, as large plastic storage containers full of very large snakes are unloaded from vehicles and stacked on folding tables for display.)
—*Pets in America* by Katherine C. Grier, 2006

If one tracks the development of herpetoculture by using reptile dealer price lists as a source, major trends are apparent. Due to loss of biodiversity and the public perceptions about animal protection, one will never again see the array of wild-caught amphibians and reptiles offered for sale 50 years ago—a statement as to how the world has changed. Changes are the result of shrinkage of wild populations due to habitat destruction, arrival of invasive species, chemical contaminants, infectious diseases, over-collecting, human consumption, reptile skin trade, and better captive husbandry and increased sophistication of the customers. We will examine the types of dealers (large-scale importers, biological supply houses, mass breeders, smaller private breeders, zoos and aquariums) from the perspective of animal availability, types of animals, quantities, and price. "Dealer" can mean collector (in the wild), exporter, trader, importer, and breeder. These persons were (or are) the sources of animals; their clientele were (and are) pet shops, pet owners, hobbyists, private breeders, schools and universities, traders, other dealers, zoos, museums, aquariums, and roadside attractions. There is a broad spectrum encompassed by suppliers and customers.

Also there have been changes in technology, starting from lists published in early books and magazines, on to mass mailings of mimeographed lists and evolving through facsimile distribution to Internet sites and e-mail. It is almost certain that the bulk of commerce now occurs through the Internet (Trooper Walsh, pers. comm.).

This is not an exhaustive compilation or examination of all price lists but rather a selection relevant to the history of captive herp keeping and reflective of changes in the natural world and in animal commerce. We do not in this paper propose to be the definitive source of information about the world of herpetology and herpetoculture. While we recognize that economic incentives have led to smuggling and other illegal activities, we have chosen not to focus on the perpetrators; this aspect of the animal trade has been extensively covered in other publications, for example *Animal Underworld* by Alan Green.

What We Have Experienced

Those who care for the study of Amphibia and Reptiles—the Herpetologists, to give them their scientific title—have never been numerous; but most of them have been serious students. One reason for the fact that this branch of Natural History is not very popular, is a prejudice against creatures some of which are clammy and cold to the touch, and some of which may be poisonous. People who delight in keeping Newts or Frogs, Tortoises, or Snakes, are, as a rule, considered eccentric.

—Hans Gadow, 1901

One of us (JBM) was curator of herpetology at the Dallas Zoo in Texas for 30 years. JBM is currently Smithsonian Research Associate and interim Curator at the National Zoological Park in Washington DC. The other (KM) worked for the US Fish & Wildlife Service for over 31 years in the Office of Law Enforcement, as "Office's national herpetology expert" specializing in herp smuggling and poaching investigations, writing herpetology books and identification papers, and provided training to state and federal conservation agencies. KM now works as a Major Crimes Investigator, Peninsula Humane Society and Society for the Prevention of Cruelty to Animals in San Mateo, California. Both of us are retired from full-time work. Having been interested in the keeping of herps from an early age, we have watched the major changes relative to the business of selling living amphibians and reptiles for approximately 50 years.

Many of the amphibians and reptiles we kept as children were acquired from variety stores (often called five and dime stores) in the US: baby turtles, some with decals and painted shells; horned lizards; Green Treefrogs; American Anoles (also known as Green Anoles); Red-spotted Newts, and occasionally baby American Alligators or Spectacled Caimans. In the variety stores, most animals were kept in deplorable conditions and carcasses often littered the enclosures. As our interests broadened, we graduated to the next level: checking the local pet shops where there were often more interesting amphibians and reptiles for sale. As our interests became our obsessions, we obtained price lists from animal dealers in far-away places, ordered some of our favorites which arrived through the mail or by railroad express, and we personally visited many of the establishments during school holidays. When KM was 15 years old, he amassed a crocodilian collection which lived in a large child's plastic wading pool in his bedroom and included False Gavials, Salt Water, American, and Nile Crocodiles, and Spectacled and Yacare Caimans.

Key pieces of legislation were enacted and this legislation impacted the trade. The United States Lacey Act, passed in 1900, controlled the trade in wild birds and game and subsequently was extended to cover most animal and many plant species. The Act prohibited the importation, exportation, transportation, sale, receipt, acquisition, or purchase of any animal or plant that was obtained or transported in violation of any other wildlife conservation law or regulation. The United States Endangered Species Act (1973) and the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) were also legislative tools to control importation of species at risk. In 2002, legal wildlife trade to the US alone included more than 2 million reptiles and 49 million amphibians, according to Sharon Guynup in 2006.

Reptile and animal dealer William Abraham King was called "Snake King" and his business was known as "Snakeville." The compound, established in 1907, was in Brownsville, Texas and many of his snakes were sent to carnivals and traveling circuses. This ad features a Neotropical Rattlesnake (*Crotalus durissus*) in a defensive pose. The "horn" appears to be a cock spur. His autobiography was published in 1964 and titled *Rattling Yours—Snake King.* Credit: Courtesy of Patrick Burchfield, Director, Gladys Porter Zoo, Brownsville, who acquired King's snake hook, protective leggings, and other memorabilia.

We will show a number of price lists, mostly from KM's collection, which graphically demonstrate changes in the animal trade—both the types of animals for sale and prices. As an example of what was available, there was a 1962 publication connected to Ross Allen by Dick Bothwell called *The Great Outdoors Book of Alligators*. It has a chapter (pp. 61–64) entitled "Crocodilian As a Pet," in which the author refers to G. L. Thompson of Lane Wilson Company in Monroe, Louisiana claiming to ship 500 caimans a week to pet shops in the US. The numbers and varieties of venomous and potentially dangerous wild-caught species offered for sale during the mid-20th Century were amazing and prices were very low. Price lists 50 years ago from Jonathan Leakey and C. J. P. Ionides offered all sorts of wild-caught African vipers, mambas, cobras, and so on. KM ordered a shipment of baby Puff Adders and Rhinoceros Vipers from Leakey when he was 15 years old and enjoyed watching the snakes crawl around his back yard, much to the horror of his mother. Since he did not own a snake hook, he fashioned a surrogate out of a wire coat hanger.

In addition to the herps available, some of the lists being circulated offered primates, baby elephants, large cats such as jaguars, tigers, and lions, capybaras, tapirs, rare parrots, etc. We visited some wholesale tropical fish outlets where massive numbers of herps were stockpiled, sometimes in horrendous conditions. Conversely, we visited specialty shops catering to the serious collector where the animals were kept singly or in small groups in excellent conditions. We have seen the appearance and rise of commercial breeders and expanded interest in conservation issues. Commercial reptile breeders do take pressures off of wild populations but it is only fair to show that there may be downsides to the acquisition of breeding stock as well. And for those of us who have kept herps since childhood and later made a living, albeit modest, working with them, we would hate to see the day where a budding enthusiast would not have a chance to keep some as we did but we also stress that it must be done with good care and conservation in mind.

The Case of the Ball Python

THE WAY THINGS ARE MOVING IN AFRICA, THE TIME WILL SOON BE PAST WHEN EVEN A GOOD FIGHT CAN SAVE ANYTHING MORE THAN SCRAPS.

—ARCHIE CARR, *ULENDO*, 1964

IN GENERAL, WE FEEL THAT IT IS DIFFICULT TO JUSTIFY THE TRADE IN WILD-CAUGHT BALL PYTHONS, PARTICULARLY IF ONE CONSIDERS THE AVAILABILITY OF CAPTIVE-BRED AND CAPTIVE-HATCHED ANIMALS. OF COURSE, WITH FEW EXCEPTIONS, IT IS WILD-CAUGHT SNAKES WITH ANOMALOUS APPEARANCES THAT HAVE FOUNDED MOST OF THE LINEAGES OF THE MORPHS THAT ARE BEING CAPTIVE-BRED TODAY.

—DAVID G. BARKER AND TRACY M. BARKER, *BALL PYTHONS,* 2006

In this section, we deal with the challenges facing future conservation initiatives: basic needs of the collectors and exporters living in range countries, the justification for exporting large numbers of living amphibians and reptiles, the fate of these imported fauna, and the importance of captive breeding. These are not new ideas because conservationists have grappled with these issues for decades. For our model, we use the African Ball or Royal Python (*Python regius*). It is one of the mainstays of the exotic reptile trade due to its smallish size, calm temperament, long life span, and multitude of spectacular color morphs.

To begin our analysis, we feature a comprehensive book by David G. Barker and Tracy M. Barker: *Ball Pythons: The History, Natural History, Care and Breeding* (2006). In their book, the authors make several important points:

- More Ball Pythons are purchased annually than all other pythons combined.
- The number of Ball Python color morphs is astonishing and many are pictured beautifully in the Barker book. More than two hundred pictures show wild and designer morphs, listed with colorful names affixed to them by the breeders like pewter, piebald, paradox-albino, super phantom, and killer-bee.
- The coastal areas of Ghana and Togo are the source of many imported Ball Pythons.
- Although exact numbers remain elusive, estimates of up to one adult snake per acre might be accurate, according to a study by Gorzula and associates in 1998.
- Native local collectors are extremely proficient at collecting Ball Pythons.
- Ball Pythons are either collected from the wild, captive-hatched from eggs retrieved from wild gravid females, or bred in captivity.

"The captive breeding of original morphs is both accidental and inevitable, and only intentional when crossing morphs; the resultant progeny are usually then referred to as 'designer' morphs, even with single species hobby enthusiasts. Consider enthusiasts of roses, hamsters, or pigeons, as single species hobby examples (Charles Darwin chose pigeons in particular to practically illustrate the enormous diversity of genetic potential). Pigeon fanciers are not generally interested in obtaining new species of bird." (Jon Coote, pers. comm.).

The Ball Python market is illustrative of a core conservation dilemma: human needs balanced against Ball Python sustainability. In *The World Factbook*, average annual income per capita [GDP-Gross Domestic Product] converted to the US dollar was ranked for 229 countries throughout the world: Ghana ranked 200 with income of $1400 and Togo ranked 215 with income of $900. In African countries beset

Ball Pythons (*Python regius*) are imported in large numbers for the exotic reptile trade. Illustration from *Iconographie générale des ophidiens / par M. le professor Jan . . .[en collaboration avec Mr. F. Sordelli.] ...*
Imprint: Milan: chez l'auteur, [etc., etc.], 1860–1881.

with political strife, declining infrastructure, and few resources, it is completely understandable that locals collect Ball Pythons, especially those snakes with unusual colors and patterns, in order to make a living. In Ghana, trappers support an average of 10 family members and have few alternatives for employment other than snake collecting; a harvest of 7000 wild adults and 3500 gravid females represents an annual income of $925 US for a trapper (Gorzula et al. 1998). Traders want to satisfy customers but may not be sure precisely what the buyers want so all of the snakes are likely shipped.

If an aberrant snake such as an albino is collected, it is a valuable find: one was able to fetch US $7500 in the US in 1998. About six years ago, the most ever paid for a mutant ball python in the United States was US $130,000 for a wild caught adult female leucistic morph. Two other snakes were purchased for $90,000 and $100,000 respectively, of the same morph (Trooper Walsh, pers. comm.). Dave Barker (pers. comm.) said that a wild-caught leucistic male sold for $175,000, bought by a consortium of breeders. All of the money went into African pockets and not a cent went to a middleman; the snake sired one clutch and died.

Technology has entered the Ball Python business. Some of the big US breeders got together and purchased a laptop computer, digital camera, and a satellite phone, and gave them to the largest West African exporter who now looks specifically for gravid females and any unusual morphs. If a promising new morph is found in the field, a photograph is taken and immediately e-mailed to these big US breeders so that within an hour or so of discovery the snake is on its way to the USA (Trooper Walsh, pers. comm.). This arrangement may curtail the importation of unwanted snakes but the specialty breeder market is separate from the general pet market which is considerably larger.

Herpetocultural historian Jon Coote (pers. comm.) identified an economic factor in the Ball Python story which is rarely considered: "Regarding the Ball Python phenomena I would suggest that it is important to understand the reasons for the very high prices paid for unusual morphs. The pyramid market that evolved for them was fueled by the rapid inflation of assets that occurred due to the unsustainable, as we now know, cheap and widely available credit. Consider the fact also that private investors got into this market in considerable numbers who had no interest in the snakes other than their ability to generate wealth. It may well be useful to contrast this recent pyramid market with the similar market for tulips in Holland in the 1630s. Today most Ball Python morphs are available for about $100 each with even the most valuable fetching not much more than $500 each. Many of those who borrowed huge sums to set up their breeding programs are now facing financial ruin. Only those who got into the market early have actually made significant sums of money. The Ball Python market would never have evolved as it did to such dizzily high values without the unsustainable credit that fueled it, as the credit crisis that has killed it so aptly now proves. As proof look at the similar market, that preceded the Ball Pythons, for Leopard Geckos. At the height of this market the most expensive Leopard Geckos rarely fetched much more than $1000 each. An interesting point is that only reptile species that make good pets, e.g., Leopard Geckos, Corn Snakes, and Ball Pythons, have ever really established pyramid markets. The current efforts to establish a similar market in Blood Python morphs, for example, is perhaps predictably not catching on!"

In 1997, a field team led by Stefan Gorzula surveyed Ball Pythons in the whole of Ghana for CITES. In Gorzula et al. (1998) they estimated density of pythons at slightly less than one snake per acre. Based on this estimate, the projected countrywide totals in "domesticated land" [pasture] would be 18,000,000 snakes and a lower figure of 6,400,000 snakes in "crop land." In their paper, the authors presented a plan for the sustainable use of Ball Pythons which addresses the economic needs of those persons living in Ghana. CITES General Export figures for 2008 (data from CITES website) were Ghana (wild—7,000; live, ranched—50,000; live, captive-bred— 200); Togo (wild—1,500; live, ranched—62,500); Benin (wild—1000; ranched—60,000); Niger (live—500) for a grand total of 182,200 snakes.

However, the question of welfare of captive individuals of a species, and weighing that against the well being of a species in the wild, is worthy of further consideration. Are there unintended consequences once a species becomes so commonly bred and sold that it may be so easily discarded as a surplus novelty? Again, we asked Jon Coote for his perspective: "This is unlikely as the costs to produce such captive bred animals generally limit how cheap they can commercially be sold. There are 'bedroom' breeders of such things as Bearded Dragons and Corn Snakes who may well sell progeny for far less than their cost of production, and we should therefore be encouraging the pet industry to buy from reputable commercial breeders rather than from these other casual sources. The cost of production is less for many wild caught specimens, Green Anoles for example, whose cost of capture can be much less than their cost of captive reproduction, can lead to them being insufficiently valued to provide them with the captive resources that they need. It was also probably true of Green Iguanas ranched in Central America, but this trade and activity is to all extents and purposes history. In my experience here in the United Kingdom, pet reptiles are better cared for than any other category of pet based on the comparison between the numbers kept and the numbers placed in pet rescue centers. The worst pet keepers, here in the United Kingdom, based on the same criteria are keepers of first dogs, then cats and then rabbits."

In order to gain another perspective, we asked Ken White, President of the Peninsula Humane Society & Society for the Prevention of Cruelty

to Animals (SPCA) in the USA, to comment on his experiences: "It is obvious, at least for the 30 years I have been in the field, that reptiles are victimized through neglect and abuse much in the same ways we see with dogs, cats and other pet animals, and that exotic pets also enter animal shelters in need of great help. But while the past brought us a large number of a few species—mostly Iguanas, Red-eared Sliders and Snapping Turtles, caimans, and the more common large constrictors—the exotic pet industry's growth has expanded the number of species showing up at humane societies and SPCA's [facilities] around the country. Today, in addition to what we have always seen, shelters are working to care for increasing numbers of Bearded Dragons, Leopard Geckos, *Phelsuma* species, Mediterranean and African tortoises, and amazing numbers of Ball Pythons. In those animal shelters near larger cities, it is not uncommon to find Australian herps (from Carpet Pythons to Blue Tongue Skinks) added to the mix as well, along with other even more exotic species.

"And while some may laud the captive breeding of exotics as a way of decreasing the demand on wild animals by substituting with a captive bred supply of the so-called designer morphs, shelters see the other side of this coin. That is, ever increasing numbers of captive bred animals being deprived of basic husbandry and veterinary requirements, sold by an innately exploitive industry to families jazzed about adding 'something different' to the family."

Is Captive Breeding a Conservation Tool?

Are captive breeding and re-introduction viable options for conservation? Members of the Species Survival Commission (SSC) within the International Union for Conservation of Nature and Natural Resources (IUCN), the largest conservation organization in the world, certainly think so as there is a Conservation Breeding Specialist Group and Re-Introduction Specialist Group within the organization. Five Specialist Groups and Task Forces represent herps: amphibians, crocodilians, iguanas, marine turtles, and turtles. The organization views its role this way on its website: "Our vision is a just world that values and conserves nature. Our mission is to influence, encourage and assist societies throughout the world to conserve the integrity and diversity of nature and to ensure that any use of natural resources is equitable and ecologically sustainable." IUCN provides a variety of training sessions and tools to accomplish this goal, from the mechanics of small animal population management to creating and evaluating genetic models for breedings. Commercial animal breeders have proven that huge numbers of animals can be produced, from parakeets to ball pythons, and we believe that these operations could be a considerable positive force in future conservation programs if they could embrace the mission of the IUCN and other conservation organizations to assist in developing protocols, techniques, and networks for captive breeding for possible re-introduction. However, the possibility of re-introduction should be mentioned only with a large caveat. There are many questions concerning genetics, community structure, introduction of disease, preparing captive-bred animals for a life in the wild, assessing competence to survive and reproduce over generations, and other factors that have not yet been resolved. There are cases of successful re-introductions and translocations of amphibians and reptiles into the wild but examples of failures as well (see Dodd and Seigel 1991; Germano and Bishop 2009). Large iguanine lizards are good candidates for headstart and release (Jamaican Iguana and Anegada Iguana release) and for captive breeding and release (Grand Cayman Iguana) and they respond well to that conservation strategy (Alberts et al. 2004; Hudson 2006; R. Hudson, pers. comm.)

As an example of using the IUCN approach toward partnerships, this is already being done through the SSC Turtle Survival Alliance (TSA), a cooperative arrangement of private breeders and zoological institutions. "The mission of the TSA is to develop and maintain an inclusive, broad-based global network of collections of living tortoises and freshwater turtles with the primary goal of maintaining chelonian species over the long term to provide maximum future options for the recovery of wild populations" (Lawson 2004).

In any program using animals removed from the wild, the captive manager would be well-served to remember the cautionary words of the late Henry Fitch written in 1980: "Thus, captivity will result in intensive selection, molding the animal in a manner quite different from that followed in its natural environment. The final product will be an animal much better adapted to live in close association with humans, in the home or laboratory, but less well adapted for life under natural conditions."

Original traits of a species will tend to be altered in captivity: generation time is shortened; captives are less exacting in their requirements for mating; fertility is increased; and intervals between clutches or litters are shortened. These are trends well known in domestic animals (Darwin 1868). There is no doubt that we are seeing these trends now in our captive herps. In fact, The Herpetologists' League (HL) views the production of designer herps as an ethical issue and takes a strong stand against it: "Because the practice does little to advance society's understanding of amphibian and reptile biology, HL hopes that its members will avoid the capture/purchase and captive breeding of herpetofauna with the express purpose of producing anomalies in body form, coloration or pattern" (<http://www.herpetologistsleague.org/en/ethics.php>).

Reptile and Amphibian Availability over Time

Interest in reptiles and amphibians is growing rapidly. Pet shops abound with scaly forms, reptile clubs are on the increase, and a small army of snake and lizard hunters roams the countryside. Along some of our desert roads collectors may outnumber the snakes, and in some of our large municipal parks hillsides may be dotted with small boys searching for lizards on a Sunday afternoon.

—Robert C. Stebbins, *A Field Guide to the Western Reptiles and Amphibians*, 1966.

—What We Saw in the United States—

From the east to west coast of the United States, amphibians and reptiles were highlighted by two of our most prominent herpetologists: Archie Carr and Robert Stebbins. Unfortunately, their concerns are now applicable throughout the world, and when we see such issues as a potential extinction event affecting amphibians that could result in the loss of an entire vertebrate class, the future is uncertain (see Wake and Vredenburg 2008; Collins and Crump 2009). We quote them here as they eloquently describe the loss of biodiversity in regions that are familiar to us.

The late Archie Carr had a love affair with Florida but worried about the state's future. In his book *Guide to the Reptiles, Amphibians, and Fresh-Water Fishes of Florida* (with Coleman Goin, 1959), he predicted disturbing trends: "We may not be able to hold on to the asset forever. Some way to do this may be worked out but so far the way has not been found. With people flocking in so fast, the day is not far off when the frog ponds will be dry and still, and the bass fishing will be all in managed water, and the only alligators will be under fence. But for the time being at least, we have a wonderful remnant of unfenced nature to color the Florida scene and we ought to enjoy it." When this book was published in 1959, Florida was indeed a different place. As a youngster, JBM traveled with his parents on annual vacations and remembers mile after mile of unbroken wilderness in the early days but depletion over time.

Part of the allure of Florida for JBM in those early days was to visit the various reptile dealers and so the pilgrimage included stops at Ross Allen's Reptile Institute, Tarpon Zoo, Ray Singleton, Charles "Bill" Chase, Thompson Wild Animal Farm, Wild Cargo, and the Miami Serpentarium. Many of these dealers employed locals to collect herps from the area and some of these collectors were very proficient and had keen eyesight. In one instance, JBM was traveling with one to learn the techniques for snake hunting. While traveling by car going 60 mph, the hunter slammed on the brakes, hopped out and grabbed a Yellow

Ratsnake crawling on a barbed-wire fence. Most dealers used outside pits to house local snakes together: numerous species, venomous and non-venomous, with well-fed Florida Kingsnakes and Eastern Indigo Snakes.

Some Florida suppliers such as Bill Chase from Miami and Tarpon Zoo in Tarpon Springs also imported large numbers of exotics, mostly from Latin America. Tarpon Zoo had large fenced areas with sizeable ponds filled with aquatic turtles, tortoises, boas, anacondas, iguanas, and crocodilians. In the middle of the lobby was a pool with enormous tame electric eels; children were petting them but apparently no shocks or electrocutions occurred.

While traveling, JBM saw that herps were rarely kept singly or in small groups at dealer compounds. Since massive shipments regularly entered the USA through Miami and local collectors worked to supply the market as well, there simply was not enough space to separate them. One could see thousands of other animals during a tour of these facilities: tarantulas, primates, psitticines, dozens of passerine birds, small mammals such as tamanduas, ocelots, and margays, and an occasional jaguar or chimp.

As Carr felt about Florida, Robert Stebbins was equally concerned about the future of herps in the western United States. In his 1966 *Field Guide* he said, "Growth of the human population brings great and rapid changes. Marshes are drained, streams are placed in concrete troughs, canyons are dammed and inundated, the ground is cleared for subdivisions and highways, agriculture spreads into marginal lands and, spurred on by water developments, reaches out even into deserts, the stronghold of reptiles. Air, water, and soil are contaminated. Although a few species may be temporarily benefited by some of these changes, most are not and the list of creatures rendered extinct in historic times

Otto Martin Locke Nursery in New Braunfels, Texas specialized in selling the fauna from the southwestern United States and Mexico. Although not well known to reptile keepers outside of Texas, the nursery was established in 1882. Credit: Courtesy of Trooper Walsh.

Revised January 1966

REPTILE PRICE LIST

CAT. NO.

Poisonous Snakes

P-1 **CASCABEL (Crotalus durissus) Tropical Rattlesnake. 2 to 4 feet.**
Small $5.00 Medium $8.00 Large $12.00 Ex. Large (4½' & over) $15.00
Handsomely marked with large brown diamonds bordered with light yellow, and a pair of vivid longitudinal bands on the neck. Feeds on birds, rabbits and rodents.

P-2 **EASTERN DIAMONDBACK RATTLESNAKE (Crotalus adamanteus) Florida. 18" to 5 feet.**
Small $5.00 Medium $10.00 Large $15.00 Ex. Large (5½' & Over) $20.00
Second largest type of rattlesnake... Heavy, dark body with yellow and black diamond markings. Feeds on birds, rabbits and rodents.

P-3 **PIGMY RATTLESNAKE (Sisturus miliarius) Florida. 1 to 2 feet.**
Small $1.00 Medium $2.00 Large $3.00 Over 2' $5.00
Small and heavy bodied. Light grey with black markings. Very hardy in captivity. Feed on frogs, rodents.

P-4 **COTTON MOUTH MOCCASIN (Ancistrodon piscivorus) Florida. 1½ to 4 feet.**
Small $1.50 Medium $3.50 Large $7.50 Ex. Large (4½' & over) $10.00
Heavy dark brown to a black body, with darker saddles. One of the hardiest snakes in captivity. Feed on frogs, toads, small snakes and fish.

P-5 **BUSHMASTER (Lachesis muta) South American. 4 to 8 feet.**
Small $50.00 Medium $100.00 Large $150.00
Largest of the poisonous snakes found in the New World. Very rare. Feed on birds and rodents.

P-6 **FER-DE-LANCE (Bothrops atrox) South American. 22 to 5 feet.**
Small $10.00 Medium $15.00 Large $25.00
Fairly heavy, brownish colored body, with pale yellow bands.

P-7 **GREEN TREE VIPER ( ) South American. Average size 18"** $15.00
Bright green, with pale yellow belly and prehensile tail. Feed on frogs, lizards, small rodents and birds.

P-8 **HOGNOSE VIPER (Bothrops hyoprora) South American. Average size 18"** $15.00
Rare coloration similar to that of the N. American Copperhead. Feed on small rodents and birds.

P-9 **BLACK & GREEN VIPER (Bothrops nigrovirides) South American. 18 to 30".**
Small $15.00 Medium $17.50 Large $22.50
Very rare. Body bright green with scales outlined in black. Feed on small rodents and birds.

P-10 **CORAL SNAKE (Micrurus fulvius) Florida. 1 to 3 feet.**
Small $5.00 Medium $7.50 Large $10.00 Ex .Large (40" & over) $15.00
Brilliantly colored with broad scarlet and black rings, separated by narrow yellow rings. Tip of nose black, with blunt head. Feed on small snakes, lizards and earth worms.

P-11 **CORAL SNAKE (Micrurus spixi) South American. 2 to 4 feet.**
Small $15.00 Medium $20.00 Large $25.00 Ex. Large (4' & over) $30.00
Has bright red rings separated by very wide black rings in triads. Each of the black rings contain two narrow yellowish-white rings Feed on small snakes, lizards and earth worms.

P-12 **CORAL SNAKE (Micrurus—various species) South American. 18" to 3 feet.**
Small $10.00 Medium $15.00 Large $20.00

Mildly Poisonous Snakes
(Rear Fanged)

M-1 **GUARDA CAMINO (Conophis lineatus) South American. 1½ to 2 feet** $2.00 to $3.50
Tan with black longitudinal stripes. Very gentle and hardy. Feed on lizards and snakes.

—1—

Tarpon Zoo was located in Tarpon Springs, Florida and was owned by Trudy Jerkins and Mike Tsalickis. Tsalickis set up an export facility in South America to supply Tarpon Zoo, resulting in the importation of many species rarely seen in the US. The animals were listed by region: 13 species of venomous snakes, 9 of rear-fanged snakes, 17 non-venomous snakes from Florida, 22 non-venomous snakes from South America, 11 of lizards from South America, 22 types of Florida and South American chelonians, and 4 of crocodilians. Cages, plants, live foods, and insects were also offered for sale. Most of the herps were kept in large outdoor enclosures. Credit: Courtesy of Trooper Walsh.

Hermosa Reptile and Wild Animal Farm was located in Hermosa Beach, California and was owned by Ray Folsom and his wife Gini. This was one of the largest operations in the US. His lists were sent monthly to customers for US $1.00 to cover mailing costs annually. This list shown here included 26 types of venomous snakes, 11 of rear-fanged snakes, 28 of non-venomous snakes, 22 of lizards, 26 of chelonians, 2 of crocodilians, and 22 of amphibians including Chinese Giant Salamanders (*Andrias davidianus*) for $100.00 each. In another list, 52 species of amphibians were for sale, mostly from the United States. Mammals and birds were also available, including douc langurs, tapirs and black bears.

Folsom possessed one of the largest personal collections of rattlesnakes ever assembled, which were kept at his home. Virtually all of the US forms were represented and a considerable number from Latin America as well. Credit: Courtesy of Trooper Walsh.

can be expected to grow. The trend is toward an ordered, domesticated world, reduced in organic variety and crowded with people and their possessions. Interest in wildlife preservation cannot be separated from concern with efforts to limit human population growth and prevent careless exploitation of remaining natural areas."

There were several large dealerships in California during this time: Hermosa Reptile and Wild Animal Farm in Hermosa Beach, Western Zoological Supply in Monrovia, and East Bay Vivarium in Oakland which still exists today, making it the oldest continuous specialist reptile store in the USA. We occasionally visited these places and were impressed with the wide range of species available for sale. In fact, one of us (KM) worked at two of these places when he was young. As a 14-year-old adolescent already obsessed with herps, he was the first (or one of the first) of owner Ronald Cauble's original employees at East Bay Vivarium when this retail reptile store first opened in Oakland. KM would travel by bus and/or train for three hours each way for the opportunity to work each Saturday cleaning cages. For reimbursement, he received a meager pittance: costs of the travel fares (buses and train) and a cheeseburger and fries at lunch time. Later, KM was employed at Western Zoological Supply where he learned to work with huge assortment of herps, including many venomous reptiles.

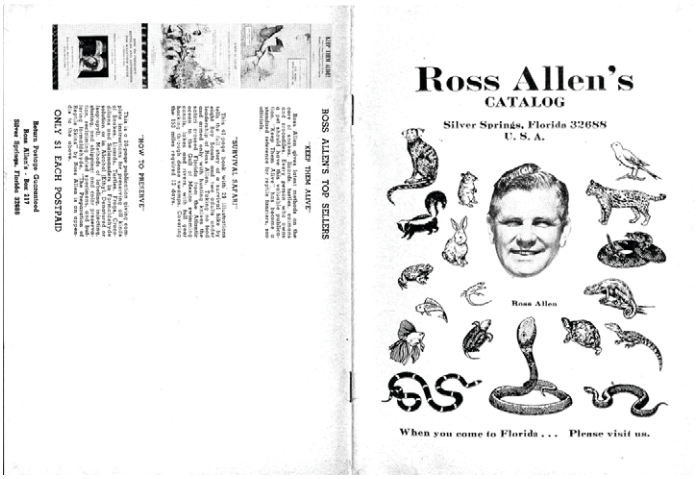
BARNEY TOMBERLIN — MEMBERS A.A.Z.P.A. — JIM BROCKETT



Western Zoological Supply in Monrovia, California, was one of the largest operations on the west coast of the US during the mid-1970s. Since the weather was generally pleasant, lizards, tortoises, and other reptiles could be kept in large outdoor enclosures throughout the year, such as a number of chameleon species.

—The Trade Between 1940 and 1970—

"Easy to keep" is a quality which must be differentiated sharply from the conceptions "hardy" or "resistant." By keeping a living thing in the scientific sense we understand the attempt to let its whole life cycle be performed before our eyes within the narrower or wider confines of captivity. Nevertheless, those animals are usually deceptively termed easy to keep which, in reality, are merely resistant and, to put it crudely, take a long time to die. The classic type of this type of animal is the Greek tortoise. Even under the inadequate treatment of the average ignorant owner, this poor beast takes three, four or even five years until it is really, thoroughly and irrevocably dead, but, strictly speaking, it starts on the downward path from the first day of its captivity. To keep tortoises so that they grow, thrive and multiply, they must be offered conditions of life which, in a town flat, cannot be achieved, In our own climate, nobody, to my knowledge, has truly succeeded in breeding these animals.

—Konrad Z. Lorenz, *King Solomon's Ring,* 1952

When in grade school in the 1940s, JBM ordered a "hatchling aquatic turtle den" from a dealer's price list. The transaction was to include a dozen individuals of at least six species. The shipment was packed in a large, very heavy, reinforced wooden crate and was shipped via railway express. The shipping fee was staggering and upon opening the box, a dozen adult box turtles peered out of the container. A steady stream of complaints from the recipient to the supplier ensued but none was answered; U. S. Postal Service mail fraud charges were initiated. Several years passed but justice prevailed and the proper animals were eventually received. JBM accosted the dealer—an unkempt person with beer in hand, unshaven, un-bathed, and sloppily dressed with shoes untied— at his compound. When asked why he never responded, he said that he had just been released from jail. Since the supplier was anxious to avoid additional legal difficulties, JBM left with far more herps given as

Ross Allen

When you come to Florida . . . Please visit us.

Ross Allen's Reptile Institute was located in Silver Springs, Florida and featured one of the largest crocodilian collections ever assembled. His Institute offered three publications for sale: "Special Publications," "Publications of the Research Division," and "Bulletins." The "Bulletins" covered topics ranging from snake biology and husbandry to disease treatment for captive specimens. Allen also created the Research Division in 1949 and hired Wilfred T. Neill (1922–2001) as director. Allen and Neill published a large number of short papers in *Herpetologica* and *Copeia*. This catalogue was published around 1960. Allen offered many supplies for the snake hunter: manuals, snakebite kits, hooks, tongs, snake-proof boots, transport boxes, and cloth bags. Credit: Courtesy of Dave Barker.

Ronald L. & Marilyn Tremper, owner/Breeder

-over-

The **Center for Reptile and Amphibian Propagation** in Fresno, California specialized in propagating rare lizards, such as many of the Madagascan chameleons and geckos, and the New Caledonian Giant Geckos. Owner Ron Tremper was formerly herpetological curator at Fresno Zoo in California. The operation is now located in Boerne, Texas.

1	Reticulated Python(Python reticulatus)11' Captive raised.	$275.00
2	Burmese Pythons(Python molurus bivittatus)12 & 13' Captive raised.	$400.00 & $450.00
2	Burmese Pythons(Python molurus bivittatus)8' Captive raised.	$200.00
1	Burmese Python(Python molurus bivittatus)6' Captive raised.	$125.00
6	Burmese Pythons(Python molurus bivittatus)2' Captive born.	$50.00
1/1	Ceylonese Pythons(Python molurus pimbura)7' Long term captives.	$800.00 pr.
1/1	Carpet Pythons(Python spilotus)3' Captive raised.	$300.00
1/0	Solomon Island Ground Boa(Candoia carinata paulsoni)1½' Captive raised.	$175.00
1/2	Jamaican Boas(Epicrates subflavus)1½-2½' Captive raised.	Inquire
1/1	Bimini Boas(Epicrates striatus fosteri) 4 & 5' Captive raised.	$275.00 pr.
1	Caicos Island Boa(Epicrates c. chrysogaster)3½' Captive raised.	$250.00

The Shed in Miami, Florida was one of the premier dealerships in the southeastern United States during the mid-1970s. One of the owners, Louis Porras, has written many herpetological papers and coauthored a book on invasive amphibians and reptiles in Florida. Porras took JBM on collecting trips around Miami to show the extent of the many foreign introductions: Knight, Jamaican, Puerto Rican Crested, and Bark Anoles, Green and Spiny-Tailed Iguanas, Brown Basilisks, Tokay and Yellow-Headed Geckos, and Cuban Treefrogs. The search for Spectacled Caimans along the canals was unsuccessful. One striking feature was the number of exotic fishes released into the Everglades which seemed to outnumber the native species in biomass: Oscars, several species of *Tilapia*, *Plecostomus*, several Latin American cichlids, and some killifish.

"gifts" than had been initially ordered. This dealer's snakes were kept in a ramshackle tin/wooden shed in long wooden boxes filled with sawdust. Two of the largest cottonmouth moccasins imaginable were held in an oil drum half-filled with water; the ophidians swam without stopping. The dealer was afraid that the snakes would crawl over the side of the container and escape if they could brace themselves on the bottom.

Virtually anyone at least a half-century in age can remember pithing and dissecting a live frog in high school biology lab. There were several suppliers in the US who specialized in providing a variety of amphibians and reptiles for the classroom: William A. Lemberger Co. in Oshkosh, Wisconsin; Quivira Specialties, operated by herpetologist Dr. Charles Burt in Topeka, Kansas; Ward's Natural Science near Rochester, New York; and herpetologist Ottys Sanders' Biological Supply Co. outside Dallas, Texas. The species usually offered were common at the time: Leopard Frogs, various Treefrogs, Bullfrogs, Garter Snakes, American Anoles, Red-spotted Newts, Spotted and Tiger Salamanders, Red-eared Sliders, and Box Turtles.

In the early 1950s, tropical fish wholesalers in the United States began to expand stock by including amphibians and reptiles. Most of these entrepreneurs had little experience with herps so most were kept in large numbers in crowded conditions, just like ornamental fishes. As an example in Chicago, piles of tortoises were stacked three or four

B5	Black Rat Snake	Elaphe schrenckii	50.00.ea.
B6	Three Black-lined Rat Snake	Elaphe radiata	10.00.ea.
B7	Yellow King Rat Snake	Elaphe carinata	15.00.ea.
B8	Rare: Red Coin Rat Snake	Elaphe bimaculata	50.00.ea.
B9	Grey Rat Snake	Ptyas mucosus	8.00.ea.
B10	Green Grass Snake	Opheodrys major	5.00.ea.
LIZARDS AND FROGS			
C1	Rare: Crocodile Lizards	Shinisaurus crocodilurus	
	Adult (captive born)		80.00.ea.
	Baby (captive born)		60.00.ea.
C2	Five Lined Skink	Eumeces fasciatus	1.00.ea.
C3	Chinese Tokay Gecko	Gekko gecko	3.00.ea.
C4	Two Tailed Tokay Gecko 8"long(rare)	Gekko gecko	100.00.ea.
C5	Giant Emerald Tree Frog		10.00.ea.

Scales & Tails Trading Company in Hong Kong offered five very rare reptiles in 1986: White Head Vipers (*Azemiops feae*), Crocodile Lizards (*Shinisaurus crocodilurus*), and three species of ratsnakes (*Elaphe* sensu lato).

deep: Greek, Hermann (*Testudo* spp.), Red-Footed, and Yellow-Footed (*Geochelone* spp.). Amphibians such as Red-Bellied Newts (*Cynops pyrrhogaster*), Red-Spotted Newts (*Notophthalmus viridescens*), Roughskin Newts (*Taricha granulosa*), aquatic Caecilians (*Typhlonectes compressicauda*), Oriental Toads (*Bombina orientalis*), African Clawed Frogs (*Xenopus laevis*), and African Dwarf Frogs (*Hymenochirus boettgeri*) were available but there was often no live invertebrate prey for food. Hundreds of poison dart frogs (*Dendrobates* spp. sensu lato) were held in an aquarium with piles of tropical fish flake food scattered throughout the enclosure. The owner expressed surprise when JBM told him that frogs did not eat flake food.

One enterprising wholesaler offered "Green Snake Dens" to several retail pet outlets in Chicago but later learned, to his horror, that the assemblage included Bamboo Vipers (*Trimeresurus* sp.) and Asian Vine Snakes (*Ahaetulla* sp.). Large shipments of Boa Constrictors (*Boa constrictor*), Brazilian and Colombian Rainbow Boas (*Epicrates cenchria* ssp.), and Green Anacondas (*Eunectes murinus*) regularly arrived in Chicago. Lizards included Anoles (*Anolis*), Ameivas (*Ameiva*), Whiptail Lizards (*Cnemidophorus*), Green Iguanas (*Iguana iguana*), and several types of Spiny-Tailed Iguanas (*Ctenosaura*). Spectacled Caimans (*Caiman crocodilus*) were available in large numbers.

When JBM began college in 1957 as a callow seventeen-year old youth and his parents were no longer nearby to control his impulses, he began amassing a collection of snakes, some venomous and others potentially dangerous like large constrictors. Soon the dorm room was filled with Rhinoceros Vipers, Gaboon Vipers, Indian Cobras, Gila Monsters, Bamboo Vipers, Timber and other Rattlesnakes, Copperheads, and a spectacular black Asian Spitting Cobra with a perfect white "human skull" pattern on its hood. Most of the specimens were obtained from animal dealers; no proof of age was ever requested although most lists had statements like "no venomous snakes intentionally sold to minors." In retrospect, what was most troubling was that JBM had no real experience at handling venomous snakes and no antivenin was available in case of a bite; fortunately, there were no catastrophic incidents.

One dealer offered Gila Monsters and Beaded Lizards (*Heloderma*) which appeared to be well-fed but died a month or so later. Upon necropsy, stomachs were found to be stuffed with sphagnum moss. Several species of Oriental ratsnakes (*Elaphe* sensu lato and *Spalerosophis*) were imported to the US in the mid-1970s and all died after a few weeks. Upon close examination by the Dallas Zoo veterinarian, it was discovered that gall bladders had been skillfully removed for human medicinal purposes. Prior to export, a small incision had been made but scales were never cut, only the interstitial skin, and the tiniest sutures used to complete the surgery.

One source of venomous snakes from Latin America and Southeast Asia was venom extraction laboratories but the snakes sometimes arrived clearly stressed and in poor condition due to rough handling during milking. Several other problems occurred with venomous snake importation: misidentification, especially with mimics such as False Coral Snakes (*Pliocercus*, *Erythrolamprus*) and models like Coral Snakes (*Micrurus* spp.); inaccurate counts, especially when snakes gave birth during shipments; cloth shipping bags unlabeled (especially unnerving if a spitting cobra happened to be inside); and snakes shipped either loose in the crate or having escaped from cloth bags.

ANOLIS ROQUET SUMMUS,from Martinique	US$	35.00
ANOLIS BIMACULATUS LEACHI,from Antigua	US$	45.00

Europe has always had a strong tradition in herpetoculture. Shown here is a detailed list from **Interrep Holland** offering a variety of seldom available lizards, especially Dumeril's Yellow Gecko (*Ailuronyx trachygaster*) from Madagascar. Note that only technical names are used which suggests an international clientele.

Snakes were sold by the foot or by weight by a few dealers during the 1950s in the United States. Like the average layman when estimating the size of a serpent, lengths were often dramatically overestimated by these dealers. Also, purchasing a 'mixed snake den' from a dealer's advertisement could be a risky business, for instead of the beautiful Cornsnake, Yellow Ratsnake, Chain (Eastern) Kingsnake, and Eastern Indigo Snake promised, the crate might be filled with nasty, striking watersnakes exuding foul-smelling musk. These "snake dens" were a marketing term used by a few dealers to sell a grab bag or assortment of snakes packaged in a single box. Shipments of snakes had to be examined carefully as the Snake Mite (*Ophionyssus natricis*) or ticks sometimes accompanied the consignment, at no extra charge. If the fancier wanted to reproduce herps, it was almost futile to ask for specific sexes; rather it was necessary to purchase a minimum of six individuals to increase chances of at least a pair.

Snakes and other reptiles could occasionally be purchased from dealers who also had traveling exhibitions; the advantage for the buyer was that specimens could be examined closely at the site and the best ones purchased. The late Arthur Jones, before inventing the Nautilus exercise equipment, owned a roadside public exhibit and import-export business for wild animals in Slidell, Louisiana. Jones was a pilot who flew the animals himself in old B-25 bombers. In the 1960s, he hosted a television show called "Wild Cargo." One program showed Jones capturing gigantic Nile Crocodiles and airlifting them out of the wild by a helicopter for eventual sale in the United States. In the early 1960s, Jones brought his "Wild Cargo" show to Cincinnati, Ohio (and other cities) where he constructed large wooden pits and filled them with reptiles of all sorts: Gopher Tortoises, boas, cobras, rattlesnakes and other venomous snakes, American Alligators, several types of caimans, and a variety of mostly South American reptiles. JBM was stunned and delighted to see a dozen Emerald Tree Boas in one of the pits and purchased some of them. After the show, Jones did not want to transport the animals back to Louisiana so herp lovers from the region walked out of the auditorium with dozens of bags filled with new acquisitions, some venomous, sold at reasonable prices.

1989 List of Anticipated Hatchlings – Price is in U.S. Dollars

San Luis Potosi Kingsnake *(Lampropeltis m. mexicana)* Found in the mountains of San Luis Potosi, Mexico $100
Gray-banded Kingsnake *(Lamprpeltis m. alterna)* Many color variations of the "alterna" and "blairs" phases 100
Thayer's Kingsnake *(Lampropeltis m. thayeri)* Many color "morphs." From Galeana, Mexico 100
Durango Mountain Kingsnake *(Lampropeltis m. greeri)* From the 5,000' plus mountains of Durango, Mexico 135
Guatamalan Milksnake *(Lampropeltis t. abnorma)* Beautiful tri-color when young, darkens to a dull red and black with age 200
Honduran Milksnake *(Lampropeltis t. hondurensis)* From select adults that make imported slugs look ugly 100
Sinaloan Milksnake *(Lampropeltis t. sinaloae)* Hand selected for two-generations for color. Originally from Mazatlan, Mexico 65
Mexican Milksnake *(Lampropeltis t. annulata)* Tri-colors with yellow or orange light band potential 65
Nelson's Milksnake *(Lampropeltis t. nelsoni)* Some of the few "true" *L. t. nelsoni* produced in captivity 100
Pueblan Milksnake *(Lampropeltis t. campbelli)* Probably the best selection this side of Puebla, Mexico. I have descendants of most of the wild caught ones brought into the U.S., and I know which are, and which are not related to each other 100
Big Bend Milksnake *(Lampropeltis t. celaenops)* This group originated from near Big Bend National Park, Texas. Very attractive 150
Albino California Kingsnake *(Lampropeltis g. californiae)* 60
Albino Speckled Kingsnake *(Lampropeltis g. holbrooki)* 75
Hetero Speckled Kingsnake *(Lampropeltis g. holbrooki)* 30
Mexican Black Kingsnake *(Lampropeltis g. negritis)* Many all black, some with faint patterns that darken with age 50
Ruthven's Kingsnake *(Lampropeltis ruthveni)* Resembles a California Mountain Kingsnake. From Queretaro, Mexico 90
Albino Prairie Kingsnake *(Lampropeltis calligaster)* See one, they sell themselves 100
Hetero Prairie Kingsnake *(Lampropeltis calligaster)* 35
Arizona Mountain Kingsnake *(Lampropeltis pyromelana)* 100
Albino Black Ratsnake *(Elaphe o. obsoleta)* Large, attractive with red spots. Not as ill-tempered as wild ones 75
Amelanistic Cornsnake *(Elaphe g. guttata)* Great pets 35
Applegate Albino San Diego Gophersnake *(Pituophis m. annectans)* The male was wild-caught and has beautiful orange and white color. Not many of these extremely attractive animals expected 225
Applegate Hetero San Diego Gophersnake *(Pituophis m. annectans)* This is a new albino. I don't want them confused with some of the other pure and crossed San Diego gophersnakes 50
Gila Monster *(Heloderma suspectum)* Who knows. Depends on Fish & Game and the monsters ..... ???

Robert (Bob) Applegate has been raising reptiles for sale for many years but he occupies an unusual historical place as he is the only person to advertise for a wife in his price lists. Although his attempt was unsuccessful, he did meet his current wife Marilee through mutual friends.

VPI PRICE LIST
AUGUST 1994

QUANTITY & SEX	DESCRIPTION	PRICE
10.10	**Children's python,** Antaresia childreni hatchlings.	$175.00 ea
2.3	**Spotted python,** Antaresia maculosa yearlings.	$200.00 ea
20.20	**Spotted python,** Antaresia maculosa hatchlings, priced by bloodline, pattern and overall appearance.	$100 - $250 ea
1.1	**Spotted python,** Antaresia maculosa adults, ready to breed.	$600.00 pair
10.10	**Freckled python,** Liasis mackloti mackloti hatchlings, two clutches, one from Roti Island (smaller with less-freckled pattern) and one from Timor (largest of the freckled pythons, lots of freckles).	$150.00 ea
2.1	**Savu python,** Liasis mackloti savuensis hatchlings, all unrelated.	$750.00 ea
1.1	**Ringed python,** Bothrochilus boa unrelated two years old.	$1500.00 ea
1.0	**Ringed python,** Bothrochilus boa yearling; very black ringed specimen.	$1000.00 ea
3.3	**Ringed python,** Bothrochilus boa hatchlings.	$600.00 ea
2.2	**Papuan python,** Apodora papuana hatchlings; two unrelated pairs.	$1500.00 pair
5.5	**Scrub python,** Morelia amethystina, hatchlings, banded and unbanded phases.	$350.00 ea
1.0	**Scrub python,** Morelia amethystina, yearling, banded phase.	$500.00 ea
10.10	**Jungle carpet python,** Morelia spilota cheynei, real beauties	$400.00 ea
1.0	**Jungle carpet python,** Morelia spilota cheynei, yearling, excellent feeder, yellow and black	$650.00 ea
1.0	**Jungle carpet python,** Morelia spilota cheynei, adult, proven breeder.	$900.00 ea
1.0	**New Guinea carpet python,** Morelia spilota variegata, hatchling, BEAUTIFUL.	$750.00 ea
1.1	**Angolan python,** Python anchietae, hatchlings.	INQUIRE
2.2	**Sumatran short-tailed python,** Python curtus curtus, hatchlings, black-headed parents.	$400.00 ea
10.10	**Borneo short-tailed python,** Python curtus breitensteini, hatchlings.	$200.00 ea
2.2	**Borneo short-tailed python,** Python curtus breitensteini, yearlings, gentle and with good growth.	$1200.00 for group or $325.00 ea
1.1	**Borneo short-tailed python,** Python curtus breitensteini, adults, ready to breed.	$1000.00 pair
5.5	**Blood python,** Python curtus brongersmai, hatchlings from red Sumatran parents.	$400.00 ea
2.1	**Blood python,** Python curtus brongersmai, yearlings, red Malaysian specimens.	$1500.00 for group
10.10	**Burmese python,** Python molurus bivittatus, normals.	$50.00 ea
10.10	**Burmese python,** Python molurus bivittatus, albinos.	$100.00 ea
10.10	**Burmese python,** Python molurus bivittatus, greens.	$150.00 ea
1.1	**Burmese python,** Python molurus bivittatus, albino-greens.	$500.00 ea
	THIS IS THE FIRST TIME THE FOLLOWING BURMESE HETEROZYGOUS CROSSES HAVE EVER BEEN OFFERED!	
5.5	**Burmese python,** Python molurus bivittatus, cinnamon-green hets.	$250.00 ea
5.5	**Burmese python,** Python molurus bivittatus, cinnamon-albino hets.	$250.00 ea
5.5	**Burmese python,** Python molurus bivittatus, cinnamon labyrinth-albino hets. NOTE: this cinnamon labyrinth is itself a new and different wild strain of the labyrinth type pattern.	$250.00 ea

Dave and Tracy Barker, owners of **Vida Preciosa International (VPI)** in Boerne, Texas, have amassed the largest captive collection of living pythons ever assembled. In addition, they have published many herpetological papers and two books on pythons. Note that the snakes on this list are sexed. The late Joe Laszlo from the nearby San Antonio Zoo published an important paper on the use of probes for sex recognition in snakes in 1975.

PYTHONS & BOAS:

1/0 BLACK HEAD PYTHON (Aspidites melanocephalus) 6' CB/CK/E/DA $7000.00
1/0 DIAMOND PYTHON (Morelia s. spilota) 4' CB/CR/DA..... $3500.00
0/1 DIAMOND PYTHON (Morelia s. spilota) 4' CB/CR/DA..... $4000.00
2/2 DIAMOND PYTHONS (Morelia s. spilota) 1' CB/DA..... $2500.00
1/0 JUNGLE CARPET PYTHON (Morelia spilota variegata) 2' CB/CS/E..... $400.00
1/0 BISMARCK RINGED PYTHON (Bothrocheilus boa) 2'+ CB/CR/ Patternless..... Inquire
4 ARU ISLAND GREEN TREE PYTHONS (Morelia viridis)1' CB$1250.00
1 BROWN WATER PYTHON (Liasis fuscus) 2' CB/T..... $175.00
1/1 TIMOR PYTHONS (Python timorensis) 5'-6' CB/E/DA..... $2000.00
5 RETICULATED PYTHONS (Python reticulatus) CB..... $ 90.00
4 BALL PYTHONS (Python regius) 1'-2'..... $ 50.00
5 BALL PYTHONS (Python regius) 2' CB/Yearlings/Chosen for Color..... $ 65.00
20 BURMESE PYTHONS (Python molurus bivittatus) 1'-2' CB $ 85.00
2/2 DUMERIL'S BOAS (Acrantophis dumerili) 1'-2' CB/CR..... $375.00
2/3 TRINIDAD BOA CONSTRICTORS (Boa c. constrictor) 2'-3' CB/CR/ 2 = A..... $300.00
1/4 PERUVIAN RED TAILED BOAS (Boa c. constrictor) 3'-4'CB$300.00
0/1 GUYANA RED TAILED BOA (Boa c. constrictor) 6'-7' CB/AC $225.00
10 ARGENTINE BOAS (Boa constrictor occidentalis) 1'-2' CB/CR $225.00
1/0 COLOMBIAN BOA (Boa constrictor imperator) 5' CB/CR..$175.00
1/0 COLOMBIAN BOA (Boa constrictor imperator) 5'-6' CR/AC$135.00
15 COLOMBIAN BOAS (Boa constrictor imperator) 1'+ CB.... $ 90.00
0/1 SOLOMON ISLAND TREE BOA (Candoia bibroni) 3'..... $150.00
3/3 BLACK SAND BOAS (Eryx miliaris magajorum) 1'-2'..... $175.00
2/2 RUSSIAN SAND BOAS (Eryx tataricus) 1'-2'..... $100.00
5 TANZANIAN SAND BOAS (Eryx colubrinus loveridgeii)'-2'$ 65.00
1/0 YELLOW ANACONDA (Eunectes notaeus) 8' CB/CR..... $250.00
0/2 YELLOW ANACONDAS (Eunectes notaeus) 4' CB/CR..... $250.00
EXPECTED SOON:
3 MADAGASCAR TREE BOAS (Sanzinia madagascariensis)1'CB Inquire
AVAILABLE:
1/1 MADAGASCAR GROUND BOAS (Acrantophis madagascariensis) 4'-5' CB/CR/E..... $10,000.00/Pair
2/0 COASTAL ROSY BOAS (Lichanura trivergata roseofusca) 2' CB/CR..... $ 90.00
0/1 ALBINO BURMESE PYTHON (Python molurus bivittatus) 9' CB/CR..... $900.00
0/1 HETEROZYGOUS (Albino) BURMESE PYTHON (Python molurus bivittatus) 11' CB/CR..... $400.00
0/1 GREEN BURMESE PYTHON (Python molurus bivittatus) 14' CB/CR..... $1375.00
0/1 HYPOMELANISTIC BURMESE PYTHON (Python molurus bivittatus) 12' CB/CR/E/Absolutely Unbelievable! A First!..... $25,000.00

RAT SNAKES, KING SNAKES, & MILK SNAKES:

0/2 ALBINO RADIATED RAT SNAKES (Elaphe radiata) 4'-5'.... $2000.00
1/0 ALBINO CHINESE BEAUTY SNAKE (Elaphe t. taeniura)5' B$2000.00
0/1 AMELANISTIC CHINESE BEAUTY SNAKE (Elaphe t. taeniura) Imperfect Eye/E..... $850.00
0/2 XANTHIC? CHINESE BEAUTY SNAKES (Elaphe t. taeniura) 4'-5' B..... $650.00
1/1 KEELED RAT SNAKES (Elaphe carinata) 3'..... $ 50.00
0/1 MELANISTIC CHINESE RAT SNAKE (Elaphe rufodorsata) 2'..$ 50.00
6 CHINESE RAT SNAKES (Elaphe rufodorsata) 2'..... $ 25.00
1 SPECKLED MANDARIN RAT SNAKE (Elaphe mandarina) 3' U..$135.00
2 MANDARIN RAT SNAKES (Elaphe mandarina) 2'-3' FI..... $ 90.00
1/1 TWIN SPOTTED RAT SNAKES (Elaphe bimaculata) 1'-2'.... $ 35.00
1 KURIL ISLAND RAT SNAKE (Elaphe quadrivirgata) 3'Unusual Population/Red Eyes..... $150.00
1/1 TRANSCAUCASIAN RAT SNAKES (Elaphe hohenackeri) 2'-3' R..... $350.00
2 PERSIAN RAT SNAKES (Elaphe persica) 1'-2' E/Different Phases..... Inquire
1 RUSSIAN LEOPARD RAT SNAKE (Elaphe situla leopardina) 1'-2'..... $200.00
1/1 LADDER RAT SNAKES (Elaphe scalaris) 2' CB/CR..... $115.00
1 PARTIAL STRIPED MOTLEY RED RAT SNAKE (Elaphe g. guttata) 2' CB/CR..... $ 50.00
2 EMORY'S RAT SNAKES (Elaphe guttata emoryi) 2'-3'..... $ 25.00
1 RED X YELLOW RAT SNAKE (Elaphe g. guttata x Elaphe obsoleta quadrivittata) 4' CB/CR..... $ 35.00
1 YELLOW RAT SNAKE (Elaphe obsoleta quadrivittata) 5' CB/CR..... $ 25.00
0/1 GRAY X YELLOW RAT SNAKE (Elaphe obsoleta spiloides x E. q. quadrivittata) 3'-4' CB/CR/E..... $ 35.00
3 EVERGLADES RAT SNAKES (Elaphe obsoleta rossalleni)'CB ..... $ 25.00
1 BRINDLE BLACK RAT SNAKE (Elaphe o. obsoleta) 1' CB..$ 35.00
1 BLACK RAT SNAKE (Elaphe o. obsoleta) 2' CB/CR..... $ 15.00
1 BLACK RAT SNAKE (Elaphe o. obsoleta) 4'-5' CR..... $ 25.00
0/2 TEXAS RAT SNAKES (Elaphe obsoleta lindheimeri) 4'-5' CB/CR..... $ 17.50
1/0 TRAYER'S KING SNAKE (Lampropeltis mexicana thayeri) 2'-3' CB/CR/Milk Snake Phase..... $150.00
1/0 NELSON'S MILK SNAKE (Lampropeltis triangulum nelsoni) 1'-2' CB/CR..... $100.00
1/1 NEW MEXICO MILK SNAKES (Lampropeltis triangulum caelenopa) 2' North Texas Population..... $100.00
0/1 ARIZONA MOUNTAIN KING SNAKE (Lampropeltis p. pyromelana) 1'-2' CB/CR..... $125.00
1 CALIFORNIA KING SNAKE (Lampropeltis getula californiae) CB/Banded..... $ 40.00
0/1 STRIPED CALIFORNIA KING SNAKE (Lampropeltis getula californiae) 3' CB/CR..... $ 50.00
6 DESERT KING SNAKE (Lampropeltis getula splendida) 2'-3' ..... $30.00-$ 40.00

Zooherp in Sandy, Utah, occupied a specialized niche by mostly providing amphibians and reptiles for zoos and aquariums. Note the codes describing the specimens.

East Bay Vivarium

Specializing in Reptiles and Amphibians since 1970

1511 MacArthur Blvd., Oakland, California 94604, U.S.A.

JUNE 1973 PRICE LIST

SNAKES

2	CARPET PYTHON	Morelia argus variegata	3 & 4'	150.
0.1	RETICULATED PYTHON	Python reticulatus	15'	550.
	-this captive raised python is 5 years old and totally tame.			
2	RETICULATED PYTHON	Python reticulatus	5 & 6'	40.
*	RETICULATED PYTHON	Python reticulatus	babies	30.
1.0	INDIAN PYTHON	Python m. molurus	11'	350.
	-captive raised; very heavy bodied.			
5	INDIAN X BURMESE PYTHON	Python m. molurus X bivittatus	babies	65.
	-these products of the captive breeding of an Indian and a Burmese Python we hatched in late May.			
3.0	BURMESE PYTHON	Python molurus bivittatus	9 - 10'	175.
1.0	BURMESE PYTHON	Python molurus bivittatus	6'	75.
	-the above three Burmese are flawless and completely tame.			
3	BURMESE PYTHON	Python molurus bivittatus	babies	50.
1	BALL PYTHON	Python regius	3'	50.
1	BLOOD PYTHON	Python curtus	43"	125.
	-this captive raised snake is the most beautiful specimen I've seen.			
1	BLOOD PYTHON	Python curtus	3'	100.
	-eating rats.			
0.1	AFRICAN ROCK PYTHON	Python sebae	16'	1,000.
	-this 5 year old captive raised snake weighs about 150 pounds.			
**	AFRICAN ROCK PYTHON	Python sebae	babies	35.
1	ANACONDA	Eunectes muninus	6'	75.
1	ANACONDA	Eunectes muninus	2'	50.
1	COASTAL ROSY BOA	Lichanura trivirgata roseofusca	2'	30.
3	PACIFIC RUBBER BOA	Charina b. bottae	1 - 2'	15.-20.
1.1	PERUVIAN BOA CONSTRICTOR	Boa c. constrictor	7½'	125.
1	PERUVIAN BOA CONSTRICTOR	Boa c. constrictor		90.
1.0	PERUVIAN BOA CONSTRICTOR	Boa c. constrictor	3½'	60.
0.2	COLUMBIAN BOA CONSTRICTOR	Boa c. imperator	8'	100.
1.2	COLUMBIAN BOA CONSTRICTOR	Boa c. imperator	7'	85.
0.2	COLUMBIAN BOA CONSTRICTOR	Boa c. imperator	6'	70.
1.2	COLUMBIAN BOA CONSTRICTOR	Boa c. imperator	5'	55
0.1	COLUMBIAN BOA CONSTRICTOR	Boa c. imperator	4'	40.
2	COLUMBIAN BOA CONSTRICTOR	Boa c. imperator	3'	30.
15	COLUMBIAN BOA CONSTRICTOR	Boa c. imperator	babies	15.
1.0	PUERTO RICAN BOA	Epicrates inornatus	2'	150.
	-eating mice.			

The **East Bay Vivarium** originally located in Oakland and now in Emeryville, California is the oldest continuous specialist reptile store in the USA, opening in 1970 by the original owner, Ronald L. Cauble.

—The Rise of Herpetoculture—

There is a difference between herpetoculture and herpetology. Some facets may be similar but the objective is different. The word "herpetoculture" was first coined by the late Thomas A. Huff, Director of the now defunct Reptile Breeding Foundation in Picton, Ontario, Canada, to reflect the activities of those persons, now commonly called "herpetoculturists," working with captive reptiles and amphibians. Herpetoculturists are skilled at maintaining and breeding a large variety of amphibians and reptiles for the market but these animals have essentially no niche outside of captivity. Conversely, herpetology is a division of biological sciences, and deals with systematics, measurements of selective pressures and responses of organisms to them, physiology, ethology, and natural history.

As the availability of amphibians and reptiles increased, the knowledge of how to care for them in captivity also increased; but the latter lagged rather behind the former for many years. The accretion of herpetocultural knowledge was dramatic. As an example in the history of zoos and herpetoculture, the role of temperature was properly appreciated beginning in the early 1980s. Also of importance were diets, light cycles, humidity, and treatment of diseases (see Murphy 2007 and Petzold 2007 for examples). In the late 1970s, breeding of various species became reliable but others are still reproducing unreliably, and this demonstrates how much we still have to learn.

In German-speaking areas, a number of periodicals were available to the herpetoculturist over many years: *Blätter für Aquarien- und Terrarienkunde* 1890–1901; *Wochenschrift für Aquarien- und Terrarienkunde* 1904–1950; *Lacerta* 1908–1929; *Aquarien, Terrarien* 1954–1990; *Aqua-Terra* 1964–1973; *Das Aquarium mit Aqua-Terra* 1967–1978; *Aquarien-Magazin* 1967–1978; *Die Aquarien- und Terrarienzeitschrift (DATZ)* since 1948; *Salamandra* since 1965 and *herpetofauna* since 1979.

The **First National Reptile Breeders' Expo** was held in Orlando, Florida in 1990. Wayne Hill was the organizer and continues in this capacity to this day. When Hill visited JBM in Dallas in the late 1980s and explained his vision for an annual reptile show, the latter insisted that the idea was too far-fetched and would never work; he was wrong.

As interest in the proper keeping of live herps broadened, the First Annual Symposium on Captive Propagation and Husbandry of Reptiles and Amphibians was convened by Richard Hahn in July 1976, at Hood College in Frederick, Maryland. The International Herpetological Symposium (IHS) evolved from this meeting and is still in existence. IHS provides a forum for amateurs and professionals interested in natural history, conservation biology, and the captive management and propagation of amphibians and reptiles by holding an annual meeting and publishing the papers given at the symposium.

The Northern California Herpetological Society produced a series of special publications on the captive propagation and husbandry of reptiles and amphibians in the late 1980s.

Philippe de Vosjoli founded the first nationally distributed reptile and amphibian magazine, *The Vivarium*, and an excellent line of reptile and amphibian care books published through Advanced Vivarium Systems. There are over 30 titles in this series. He popularized the terms herpetoculture and vivarium.

Mere pet owners may evolve into enthusiasts. It is certainly true that a large number of persons appreciate herps today and want to keep and study them. Many of the amphibians and reptiles available to them are bred in captivity. To prove this point, one only has to go to the Internet (http://www.kingsnake.com/) or to some of the many pet shops and reptile shows (expos) in the US and Europe and explore the number and varieties of captive-bred herps available for sale and look at the large number of books and pamphlets published on their care; it is staggering! Reptile show organizers have contributed to this change by mostly allowing only animals bred in captivity at reptile shows during the past few decades. Now price lists are filled with a myriad of captive kingsnakes, ratsnakes, and other colubrids named for breeders' lineages. Years ago, a kingsnake breeder told JBM that given enough time, he could produce a snake having a dorsal pattern with the name "James Murphy;"

he was only partially joking! At an expo, one can see hundreds of deli cups filled with baby herps with weird colors and patterns, designated with descriptive unusual names. What is striking is that the overall condition of the amphibians and reptiles for sale appears to be excellent. JBM went to the annual Mid-Atlantic Herpetological Society Expo and International Amphibian Days Expo in Maryland for several years and did not see a single unhealthy animal, at least not visibly ill to the naked eye. In fact, some organizers have arranged for outside experts to check on the well-being of the herps. It might be noted here that proceeds from some of these shows are donated to acquire protected land and support other conservation initiatives. At these reptile shows, the percentage of amphibians and reptiles bred in captivity is increasing and the number of wild-caught imported specimens is shrinking. So many are bred, in fact, that the number of new species never kept in captivity and available to the fancier is becoming limited and commercial breeders have had to create "designer morphs" to remain financially viable.

A variation of the cooperative approach by the members of the Laboratoire d'Erpetologie in Montpellier, France in the nineteenth century is currently being tried on a smaller scale in the US. In 1976, Trooper Walsh was the first private person to breed Green Tree Pythons (*Chondropython*, now *Morelia viridis*) and he has produced 10 generations of these snakes. Walsh keeps elaborate records on shedding cycles, feeding intervals, medical management, and pedigrees. Customers receive copies of these data whenever a snake is purchased. To disseminate information about these pythons, Walsh and other breeders started "Chondro Coalition" to accumulate and share knowledge regarding reptilian biology, captive husbandry, and conservation. The mission statement reads as follows: "We are a group of dedicated Chondro breeders who, while maintaining our unique identities and individual businesses, have joined together with our collective experience, resources, and energy to promote the captive breeding and long-term value of Green Tree Pythons." Unlike many other captive-bred reptiles offered for sale during the past several decades, Green Tree Pythons have not diminished in value, likely due in part to the fact that customers know precisely what the complete history is of the snake they are buying.

Concluding Remarks

THE STUDY OF REPTILES "AT HOME"—OF THEIR NATURE, HABITS, PECULIARITIES, MODE OF LIFE, OF EVERYTHING, IN FACT, BEYOND THEIR MERE ANATOMICAL CHARACTERISTICS—SEEMS TO HAVE BEEN DEFERRED UNTIL THE ENTIRE ANIMAL CREATION, EXCLUSIVE OF THE UNPOPULAR CLASS, SHOULD HAVE RECEIVED THE ATTENTION OF PRACTICAL NATURALISTS.

—"ON THE TREATMENT OF SNAKES IN CAPTIVITY" IN THE JOURNAL *ZOOLOGIST* BY ARTHUR STRADDLING, 1882

Are we in the midst of another "Fad" similar to those fern and aquaria crazes seen during the mid-Victorian era? "Out of the thousands of small mammal species that exist only a few have proven to make suitable pets. It is likely that the same thing is true of reptiles and we probably will not find that many more than we currently have. There are two parts to the reptile industry—the one for pets and the one for enthusiasts." (J. Coote, pers. comm.). There will always be that responsible group who keep living herps for personal enjoyment, contentment, and increase of knowledge, but perhaps the total number of casual pet keepers will begin to wane.

We stress here that without access to living amphibians and reptiles when we were youngsters learning about the natural world, our lives would have likely taken very different and perhaps less fulfilling trajectories. The excitement and wonder of working with these animals guided our entire professional careers and we feel fortunate to have had this wonderful opportunity. It would be tragic if this chance were to be lost to future generations. We are concerned about the increasing number of laws and local ordinances restricting the keeping of herps, based on emotion, lack of biological awareness, and ophiophobia rather than careful scientific appraisals. Our final thought—we think that careful captive breeding produces quality stock and is a reasonable approach to ensure that living herps are available to all conscientious persons.

Acknowledgments.—This contribution is dedicated to our wives Judith Block and Rose McCloud who lived betwixt and between legions of living lower vertebrates, ranging from Komodo Dragons to African Naked Catfish. They should be pelted with trophies for holding their complaints about our obsessive behavior to a minimum for years.

We thank David Barker, Judith Block, David Chiszar, Jon Coote, Gary Ferguson, Rick Hudson, John Moriarty, Louis Porras, John Simmons, and Trooper Walsh for reviewing early drafts and suggesting improvements. Smithsonian Librarians Polly Lasker, Leslie Overstreet, and Daria Wingreen allowed us to examine publications under their care and arranged loans of obscure books and papers. Mary Markey provided the opportunity for us to search through the Smithsonian Institution Archives for pertinent materials. Smithsonian National Zoological Park Registrars Laura Morse and Mandy Murphy helped by locating additional price lists. Ken White detailed information on herpetofauna released to humane societies and animal shelters. For various courtesies, we thank David Blody, Patrick Burchfield, Falk Dathe, Philippe de Vosjoli, and Bill Love.

The opinions expressed in this article are those of the authors and do not necessarily represent the opinions of any organization.

A copy of the front page of each list has been deposited in the library of the Division of Amphibians and Reptiles, United States Museum of Natural History, Smithsonian Institution, in Washington, D.C.

TABLE. 1. Here we list dealer pricelists examined during preparation of this manuscript. We collected lists from a variety of sources. It is notable that the same lists generally served the whole range of the market from the young hobbyist to the serious breeder, as well as the zoo and aquarium community. Companies are listed alphabetically, followed by owner name, location, comments, and date. In many cases, we reviewed multiple lists from a dealer but have listed only one date here.

Company Name	Owner(s)	Location	Comments	Year
AGAMA INTERNATIONAL	Bert Langerwerf	Montevallo, Alabama	Produced thousands of captive-bred lizards in outdoor enclosures	undated
AMERICAN REPTILE	Edward J. Lukacevic	Catlettsburg, Kentucky	Variety of herps	1990
ANIMAL WORLD OF MIAMI		Hialeah Lakes, Florida	Variety of mammals, birds, herps	1970
BILL JOHNSTON		Ruskin, Florida	Venomous snakes	1974
BLACK CANYON REPTILES		Tucson, Arizona	Captive-bred herps	1995
BLUE RIBBON PET FARM		Miami, Florida	Variety of herps	1975
BOTHROPS	Ron Jenkins & Jack Dambach	Ocala, Florida	Variety of herps	1983
BRIAN SHARP		Catharpin, Virginia	Captive-bred herps	1995
BREEDING COOPERATION	Klaus-Dieter Schulz & Mario Frohn	Würselen, Germany	Captive-bred ratsnakes	1990
BRONX REPTILES		Mt. Vernon, New York	Variety of herps	1988
BURGUNDY REPTILE & BREEDING INSTITUTE	Mike Ellard	Estero, Florida	Variety of herps	1990
BUSHMASTER REPTILES, INC.	Kamuran Tepedelen	Boulder, Colorado	Worldwide herps	1998
BYRON BARNES		San Antonio, Texas	Variety of herps	1994
CAL-HERP	Stephen Harkins	Upland, California	California herps	1986
CALIFORNIA ZOOLOGICAL SUPPLY	Gary Bagnall	Costa Mesa, California	Worldwide herps	1977
CAPTIVE BRED REPTILES	Ernie Wagner & Darcie Richardson	Seattle, Washington	Variety of herps	undated
CAPTIVE BRED WILDLIFE FOUNDATION	Jeff Gee & Kim Costales	Portal, Arizona	Captive-bred herps	undated
CAROLINA REPTILE	Randy McKnight	Columbia, South Carolina	Worldwide herps	1987
CASA DE PETS	Laszlo de Borondy	Studio City, California	Variety of herps	1973
CENTRAL COAST REPTILE RESEARCH CENTER	Terry Lilley & Lloyd Lemke	Morro Bay, California	Worldwide herps	1986
CENTER FOR REPTILE AND AMPHIBIAN PROPAGATION	Ron Tremper	Boerne, Texas	Worldwide herps, specializing in Madagascar lizards	1988
CHASE WILD ANIMALS	"Bill" Chase	Miami, Florida	Worldwide herps, especially Latin America	???
CHINA WILDLIFE CO.	Fred Chen	Hong Kong	Chinese herps	1970
COLD BLOOD UNLIMITED	Max Peterson & Laurel Ligon	Dallas, Texas	Variety of herps	1990
D & D ENTERPRISES	C. M. Disley &W. D. Dyson	Boroko, Papua New Guinea	PNG herps	1973
DESERT SPECIALTIES	Kerry & Gary Young	Riverside, California	California herps	1988
DIABLO VALLEY REPTILES	Chris Reimann	Pleasant Hill, California	Variety of captive-bred herps	1996
DICK GOERGEN	Dick Goergen	Alden, New York	Variety of captive-bred herps	1988
DON HAMPER		Columbus, Ohio	Variety of herps	1990
EAST BAY VIVARIUM	Ron Cauble	Berkeley, California	Oldest reptile dealer in US	1976
EAST COAST REPTILES	Michael & Carmen Powell	Miami, Florida	Variety of herps	1990
EUROTERRARIUM		Cologne, Germany	Variety of herps	1980
EXCEPTIONAL EXOTICS	Steve Hammond	Louisville, Kentucky	Variety of herps	1988
FINTIQUE		San Antonio, Texas	Variety of herps	undated
FLORIDA REPTILE AND ANIMAL EXCHANGE	Bob Udell	Miami, Florida	Variety of herps	1973
FLORIDA REPTILE IMPORTERS	Ed Chapman	Miami, Florida	Worldwide herps	1986
FLORIDA REPTILE RANCH	Vernon & Vicki Roberts	Middleburg, Florida	Worldwide herps	1986
GEORGE WATTERSON'S REPTILES	George Watterson	Medina, Ohio	Specialized in South Asian herps	1961
GLADES HERP	Rob MacInnes & Bill Love	Ft. Myers, Florida	Variety of herps	1992
GLADES HERP FARM	RobRoy MacInnes & Robbie Keszey	Bushnell, Florida	Worldwide herps	1985
GOANNA RANCH	Frank Retes	Tucson, Arizona	Varanid lizards	1996
GREAT LAKES ZOOLOGICAL SUPPLY	Tom Nelson	Warren, Michigan	Worldwide herps	undated
GULF COAST REPTILES	Chris McQuade & Eric Thiss	Fort Myers, Florida	Worldwide herps	1990
GULF HAMMOCK HERPETOCULTURE	Kevin Enright	Dade City, Florida	Captive-bred kingsnakes	1990
HENRY COHEN		Elma, New York	Variety of herps	1987
HANGZHOU LIVE ANIMAL & PLANT CO., LTD	zhiun Zhan	Hangzhou, China	Variety of Chinese herps	1996
HERMOSA REPTILE AND WILD ANIMAL FARM	Ray Folsom	Hermosa Beach, California	Wide variety of mammals, birds, herps	1967

Using Museum Frog Collections to Assign Sex and Age Categories to Frogs in Field Studies: A Case Study with the Striped Marsh Frog, *Limnodynastes peronii*

GRAHAM H. PYKE

JULIA SHOULDER
and
PAUL CHING
The Australian Museum, 6 College St., Sydney, NSW 2010, Australia
e-mail: Graham.Pyke@austmus.gov.au

In field studies of frogs, assignment of individuals to sex and reproductive age (i.e., immature vs. mature adult) categories is often desirable. For example, differences may exist between these categories in terms of habitat use (Griffin and Case 2001; Proehl 2002), movement patterns (Daugherty and Sheldon 1982; Pilliod et al. 2002; Vasconcelos and Calhoun 2004), survival (Funk and Mills 2003; Lauck 2005), or growth and development (Gramapurohit et al. 2005; Smith and Roberts 2003).

In some studies of frogs, the methods by which individuals are assigned to sex and age categories have been described (Gillespie and Hollis 1996; Lemckert 2005a, b; Palis 1998), but the accuracy of these methods has received little attention and is therefore unclear. In a rare example, Bosch and Marquez (1996) found that the sex of individual *Alytes obstetricans* and *A. cisternasii* could be determined with accuracies of about 95% and 98%, respectively, by using a number of morphological measurements.

In the case of the Striped Marsh Frog (*Limnodynastes peronii*), physical differences have been reported between reproductively mature males and females (Barker and Grigg 1977; Barker et al. 1995; Moore 1961), but it is unclear whether assignment of sex and maturity is accurate. Mature females have flanges on the inner sides of the first three fingers that are more developed on the second finger (Barker and Grigg 1977; Barker et al. 1995; Cogger 2000; Moore 1961). In mature males, the metacarpal bone of the first finger is elongated, rigid and sharply pointed at its tip and may perforate the skin to form a sharp 'nuptial spine,' the arms are often greatly hypertrophied relative to those of females (Barker and Grigg 1977; Barker et al. 1995; Moore 1961), and throats are sometimes colored with a 'yellowish wash' (Moore 1961). The 'spine' presumably helps a male grasp a female during amplexus (Moore 1961) and, as reported for other species within the same genus (Bulbert et al. 2005; Bush 1984; Clyne 1967), enlarged forearms could help a male obtain a mate through defense of a calling position or oviposition site or retain a mate during amplexus (GHP, pers. obs.). The smallest mature individuals reported were 42.5 mm SVL for females and 48.0 mm SVL for males (Barker et al. 1995; Moore 1961).

The primary focus of this study was to use museum specimens of *Limnodynastes peronii* to evaluate the accuracy of the methods described above for sexing individuals and to develop a method

for distinguishing adults from immatures, but we secondarily considered patterns in gonad size, as seasonal patterns in gonad size and development have been reported for other frog species that show seasonal patterns of breeding (Itoh et al. 1990; Kanamadi and Jirankali 1992; Ko et al. 1998; Kusano et al. 1991; Yoneyama and Iwasawa 1985). As *L. peronii* is known to breed at any time of year, we expected that there would be no seasonal pattern in gonad size for this species. We evaluated the relationships between gonad size and body size to help determine how maturity changes with body size and because gonad size has often been found to vary with anuran body size (Horseman et al. 1978; Huang et al. 2001; Jorgensen 1985; Kulkarni and Pancharatna 1996; Pancharatna et al. 2000; Prado and Haddad 2005).

Methods.—We examined 418 specimens of *L. peronii* collected near Sydney, Australia and housed at the Australian Museum. These specimens consisted mostly (N = 408) of frogs collected during 1996 on the Kurnell Peninsula (34.028°S, 151.184°E) and measured, dissected, and sexed on the basis of internal morphology at that time (A. Greer, pers. comm.). To increase the number of large frogs examined, we included an additional 10 specimens, also collected near Sydney, chosen from the same storage jars and hence collected on similar dates (i.e., day and year). All of these specimens had been collected throughout the year and we assigned collection dates to season (i.e., Sep–Nov = spring; Dec–Feb = summer; etc.).

We recorded additional data for sub-samples of the specimens. During the previous dissections, ovaries from a randomly-chosen sub-sample of female specimens (N = 106) had been examined, and removed and weighed if eggs were found. Subsequently, using Vernier calipers, two of us (i.e., AWW and GHP) measured testes lengths and widths of forearms (laterally at midpoints) for all males > 25 mm SVL (N = 94) and a randomly chosen subset of 13 in the range 20–25 mm (N = 64).

The specimens were also examined externally (by either JS or PC) and sexed on the basis of flanges on the fingers for females and nuptial 'spines' for males. An individual was categorized as a female if flanges were apparent on any of the first three fingers and a male if the metacarpal bone of the first finger felt rigid and sharply pointed to the touch. Individuals not assignable to either category were assigned the category "unknown." Throat color was not used as a characteristic for distinguishing sexes because it is known to be unreliable in this context (Moore 1961; GHP, pers. obs.) and may fade in preserved specimens. Although we measured forearm width, we did not use it for distinguishing sexes because no quantitative basis for doing this was known. External examination of specimens was carried out blind to the results of internal examinations.

Snout–vent length was recorded by at least one observer for each specimen in the sample. In those cases (N = 302) where SVL was measured during both dissection and external examination, we found a high correlation between the two measurements (i.e., Pearson correlation = 0.996), but a significant decrease in SVL of 2.2 mm on average between dissection and external examination ($P < 0.01$, paired t-test). This decrease was not significantly related to SVL ($P = 0.72$, General Linear Model). We therefore adopted the measurement taken during dissection when both measurements were taken (N = 300), but used the measurement taken during external examination and increased it by 2.2 mm, when it was the only one available (N = 2).

We used Logistic Regression to examine relationships between SVL and whether a frog was sexed and sexed correctly. We explored departures from linearity by considering the significance of SVL^2 and SVL^3, and considered sigmoidal relationships using Non-linear Regression. We examined the effects of season of collection and SVL on gonad size using Analysis of Covariance (ANCOVA) with season as the independent variable and SVL as the covariate. We then analyzed relationships between SVL and both gonad and forearm size using the General Linear Model (GLM), with departures from linearity determined on the basis of the significance of SVL^2 and SVL^3. For ovary mass, testis length, and forearm width, we used the means of left and right measurements for each individual. All analyses were carried out with the computer software SYSTAT (Wilkinson 1990).

Results.—Sexing was reliable and accurate on frogs with SVLs ≥ 40 mm, but not for smaller frogs (Figs. 1 and 2). All individuals > 40 mm SVL were sexed without error (Figs. 1 and 2). For individuals < 40 mm SVL, the proportions of individuals that could be sexed and that could be correctly sexed decreased sharply with decreasing SVL (Figs. 1 and 2). For the smallest frogs, the proportion of sexed individuals that were correctly sexed was close to 0.5 (Fig. 2), as would be expected if sexes were assigned at random. These relationships departed significantly from linearity (Figs. 1 and 2; all $P < 0.05$ for linear, quadratic, and cubic powers of SVL, Logistic Regression), and could be fitted with sigmoidal equations (i.e., $P_S = 1/ (1+506489 \times \exp [-0.414 \times SVL])$ where P_S is proportion sexed, $R^2 = 0.69$; $P_{SC} = 0.5 + 1/ (2 + 459319 \times \exp [-0.332 \times SVL])$ where P_{SC} is proportion sexed correctly, $R^2 = 0.18$; GLM). Neither mean ovary mass nor mean testes length varied significantly by season in which collection occurred ($P = 0.43$ and 0.52 respectively, ANCOVA). Season was therefore omitted from subsequent analysis.

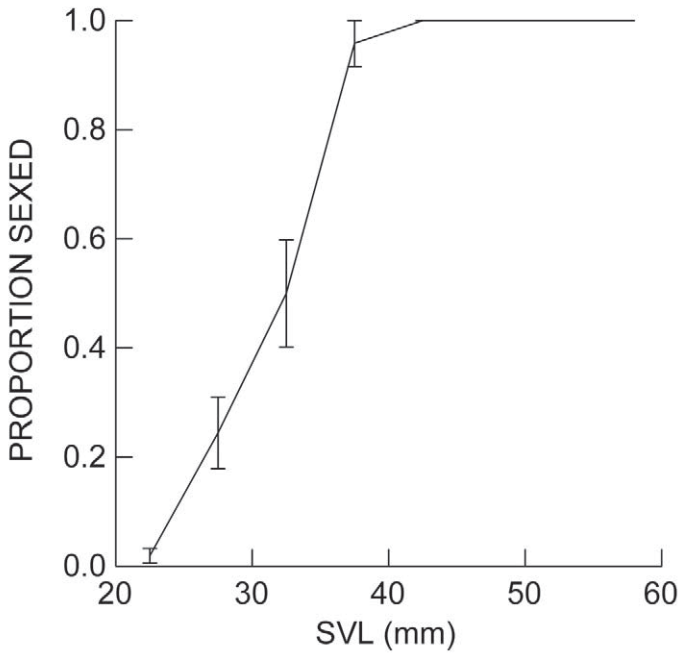

FIG. 1. Proportion of *Limnodynastes peronii* specimens that were sexed versus SVL (mm).

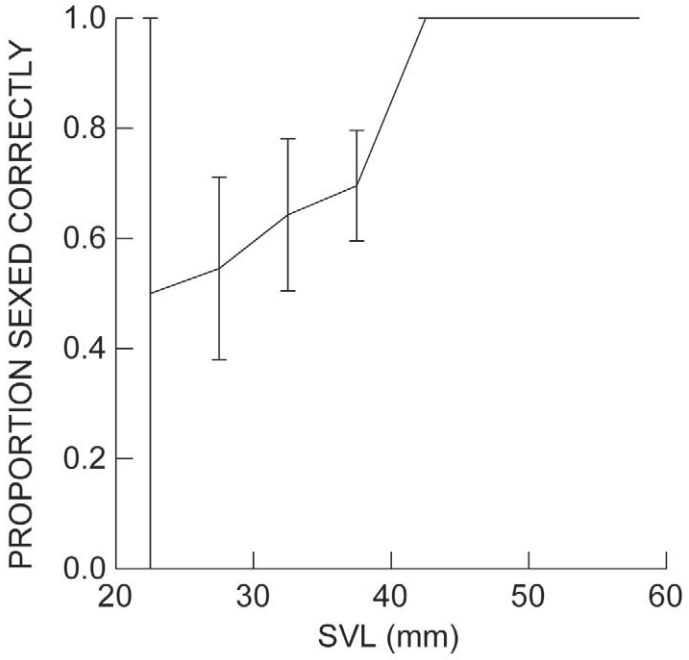

FIG. 2. Proportion of *Limnodynastes peronii* specimens that were correctly sexed versus SVL (mm).

For female frogs the proportion with eggs increased rapidly from 0 to 1 as SVL approached approximately 40 mm. We found eggs in none of the female frogs (N = 83) with a SVL of ≤ 38 mm and in two of seven 39–40 mm SVL female frogs, whereas all female frogs (N = 16) with SVL ≥ 40 mm had eggs. In addition, mean ovary mass increased as SVL increased above 38 mm (P = 0.01, GLM; Fig. 3). This relationship departed significantly from linearity (all P's < 0.05 for linear, quadratic, and cubic powers of SVL, GLM).

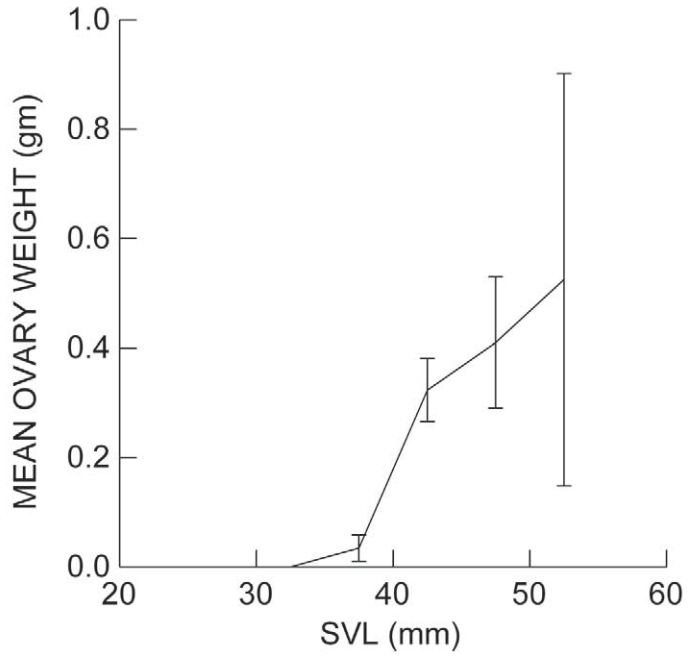

FIG. 3. Mean ovary mass (g) for female *Limnodynastes peronii* versus SVL (mm).

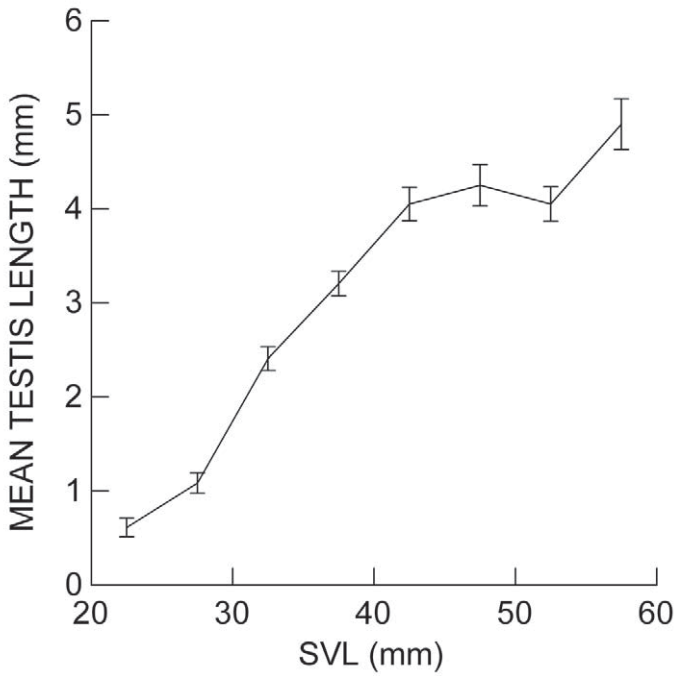

FIG. 4. Mean testis length (mm) for male *Limnodynastes peronii* versus SVL (mm).

Mean testis length increased with increasing SVL among males, leveling off after a SVL of approximately 45–50 mm (Fig. 4; all P < 0.05 for linear, quadratic, and cubic powers of SVL, GLM). Mean forearm width increased with increasing SVL among males, in a sigmoidal manner with an asymptote after about 50 mm SVL (Fig. 5; all P < 0.05 for linear, quadratic, and cubic powers of SVL, GLM).

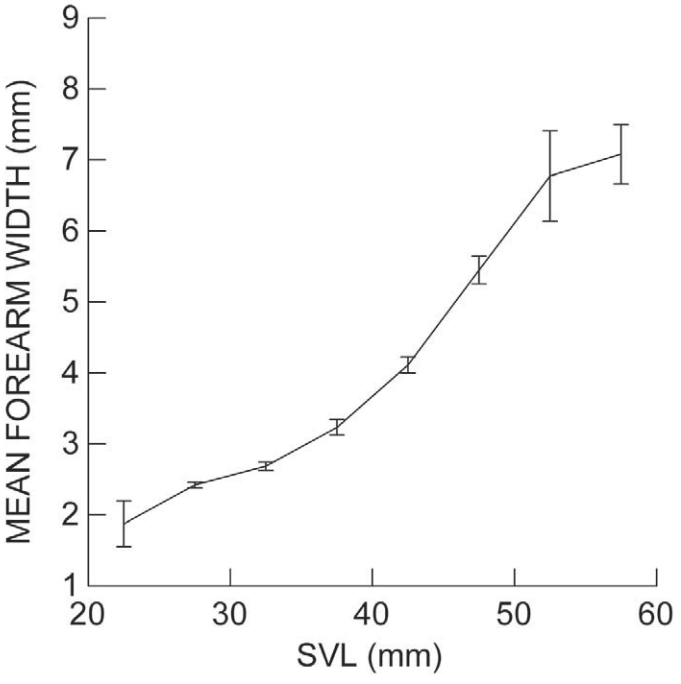

FIG. 5. Mean forearm width (mm) for male *Limnodynastes peronii* versus SVL (mm).

Discussion.—Male and female *Limnodynastes peronii* from the Kurnell Peninsula mature at different sizes. Females mature at about SVL 38–40 mm and can be considered mature at SVL ≥ 40 mm, as no females < 38 mm SVL had eggs and all > 40 mm SVL did. Males ≥ 50 mm SVL can be considered mature, as the testes attain maximum length and the forearms reach maximum width as SVL approaches 50 mm (Figs. 4 and 5). Based on data from other anurans (Pancharatna et al. 2000; Sretarugsa et al. 1997), the densities of sperm bundles and spermatozoa within the testes probably reach their maxima at maximum testis length.

Hence, individual *L. peronii* can be accurately sexed and aged (i.e., immature vs. adult) on the basis of SVL, presence/absence of flanges on fingers and presence/absence of a 'nuptial spine' with a total of four sex/age categories. All individuals < 40 mm SVL can be considered immature of unknown sex. Females ≥ 40mm SVL and males ≥ 50 mm SVL can be considered mature. Males 40-50 mm SVL can be considered immature. Similar patterns, although usually with males maturing at a smaller size than females, have been reported for other frog species (Gilbert et al. 1994).

Field observations of the sizes of mating frogs might allow further evaluation of this methodology. For example, if minimum sizes at maturity are relatively constant in this species, the smallest males and females found in amplexus would be about 50 and 40 mm SVL respectively.

The accuracies with which frogs have been assigned to age categories (e.g., immature, adult) and sexed in other studies are unclear (i.e., Bosch and Marquez 1996; present study). A general lack of discussion of this issue in the literature may reflect a similarly high accuracy in the methods for sexing and aging adopted by others. However, further tests of sexing and aging accuracy are needed to determine whether significant errors have gone unnoticed or unreported.

For both males and females, gonad size increased with increasing body size. This has been commonly observed for females of other frog species (Horseman et al. 1978; Huang et al. 2001; Jorgensen 1985; Kulkarni and Pancharatna 1996; Prado and Haddad 2005) but less frequently for males (Pancharatna et al. 2000).

Frog species with a seasonally-interrupted breeding season tend to show maximal size or development of the gonads during the periods when breeding occurs, whereas those species that breed more continuously throughout the year do not (Lofts 1974). As expected, we found no significant seasonal patterns for either mean ovary mass or mean testis length for *L. peronii*, a species reported to breed throughout the year (Anstis 2002; Cogger 2000). On the other hand, species that occur in areas where breeding is restricted to the warmer months show maximum gonad size or development during this period (Kanamadi and Jirankali 1992; Yoneyama and Iwasawa 1985).

This study illustrates one way in which a museum specimen collection can provide data that are useful and important to field ecological studies of frogs. Accurate assessments of an animal's reproductive condition or the size of its reproductive organs are generally only possible through internal examination of dead animals. Wet collections provide large sample sizes of animals, the sex of which may be verified by dissection. However, care is needed when determining relationships with body size using museum frog specimens as preservation may result in changes to morphological measurements (Lee 1982). We found, for example, a significant shrinkage in SVL over a period of about nine years after frogs were initially collected. However, we were able to rely almost exclusively on measurements taken at the time of collection and the systematic pattern of shrinkage allowed us to adjust the measurements for the few animals not measured.

Acknowledgments.—The Australian Museum supported this project. Allen Greer carried out the initial dissections and measurements, and made the resulting data available to us. No licenses or approvals were required because the study involved did not use live animals. Helpful comments and suggestions on earlier versions of this paper were provided by Hal Cogger, Paul Ehrlich, Mike Tyler, and three anonymous referees. For all of this assistance, we are most grateful.

**Corresponding author*

The genus *Emydocephalus* Krefft, 1869 includes two geographically separated species feeding exclusively on fish eggs (Voris 1966), *E. annulatus* and *E. ijimae*. Its type species by subsequent designation of Stejneger (1907) is *E. annulatus* Krefft, 1869. Boulenger (1908) recognized the validity of that genus but considered *E. annulatus* and *E. tuberculatus* Krefft, 1869 as conspecifics and added *E. chelonicephalus* Bavay, 1869 and *E. ijimae* Stejneger, 1898 as synonyms of *E. annulatus*. He considered the characters used to distinguish among all those species as inconsistent and considered the genus as monotypic, a position generally not followed later (e.g., Smith 1926).

The Turtle-headed Sea Snake, *Emydocephalus annulatus*, was originally described from an unspecified location, "*Probably the Australian seas.*" Its distribution encompasses the Timor Sea in Indonesia to northern Australia and New Caledonia, including the Loyalty Islands and the Chesterfield Reefs, as far east as Fiji (David and Ineich 1999; Ineich and Laboute 2002; Krefft 1869). The second species, the Japanese Turtle-headed Sea Snake, *E. ijimae*, was later described from the Ryukyu Sea in southern Japan. Its distribution comprises the Ryukyus in southern Japan (Stejneger 1898), People's Republic of China and Taiwan (Kharin 2008; Mao and Chen 1980), and with some doubt the Philippines (see David and Ineich 1999). Kharin (2008) suspected the possible penetration of *E. ijimae* north into Russian waters (to Peter the Great Bay) but considered the species not extending further south than Taiwan. Dotsenko (1999) also mentioned a specimen of *Emydocephalus* from Vietnam that he identified as *E. annulatus*. This record has been overlooked by most authors in the following years (Kharin 2006; Nguyên et al. 2005, 2009). Despite all those records of *Emydocephalus* from various locations between Japan and Australia, distinction of both recognized species is still weak and mainly based on inconsistent differences in scalation (see Table 1 below). Specific attribution of geographically intermediate populations of Philippines, Vietnam, and Taiwan is still uncertain, as seems to be the validity of *E. ijimae* based solely on available external characters.

Taylor (1922) reported 10 species of elapid sea snakes from the Philippines. That number was later increased to 12 by Dunson

and Minton (1978) after intensive collecting of more than 1000 specimens in the central Philippines, however these authors did not report *Emydocephalus* from the country (see also Minton 1978). Later however, Alcala (1986) reported the genus from the Philippines for the first time and referred populations to *E. annulatus*, a species that he considered as being widespread "probably all over Philippine seas." David and Ineich (1999) tentatively considered those populations as *E. ijimae*. More recently Alcala et al. (2000) mentioned Philippine populations as belonging to an undescribed species having a restricted distribution (they provide a picture of a specimen from Bohol's "Snake Reef"). That new species is not yet described but its description is underway by H. Ota (pers. comm. April 2009). Philippine populations appear to have a patchy distribution, possibly limited to the central Philippines. To date they are known from two coral reefs southeast of Bohol Island and southeast of Negros Island. This apparent restricted distribution may result from a combination of ecological, oceanographic, and climatic factors; variation in salinity may limit sea snake distributions (Heatwole et al. 2005). A similar patchy distribution was also noticed in the Philippines for the sea krait *Laticauda semifasciata* by Herre and Rabor (1949); the species can be common but is very localized and known from only a few stations.

During a diving trip, one professional diver, Vincent Maran, observed and photographed several specimens of *Emydocephalus* off the coast of Panglao Island (Bohol Sea, central Philippines). No specimens were collected but his observations and pictures were made available to us, enabling a preliminary species level identification via high quality pictures of the specimen's head. These underwater observations of Philippine Turtle-headed Sea Snakes together with the above-mentioned specimen from Vietnam generate some doubts concerning the current taxonomy in which northern populations (*E. ijimae*) are considered specifically distinct from southern populations (*E. annulatus*).

Materials and methods.—We compared 45 specimens of *Emydocephalus ijimae* from Japan with 56 specimens *of E. annulatus* from Australian waters and 18 specimens of *E. annulatus* from New Caledonia (material examined, see Appendix). The measurements and counts follow Smith (1926) with some alterations as described in Rasmussen and Ineich (2000). The following abbreviations are used: the position of the posterior tip of the heart and the anterior tip of the liver were determined in relation to the number of the adjacent ventral scales counted from throat to vent (VS–heart and VS–liver, respectively); the relative position of the posterior tip of heart and the anterior part of liver are expressed as a percentage of the total number of ventral scales (%VS–heart and %VS–liver, respectively); scale rows around neck (about one head length behind jaw's posterior end), body (about midbody) and vent (about one head length anterior of vent) are counted directly around body (SR–neck, SR–body, and SR–vent, respectively). Mean and standard deviation (sd) are given for each character counted.

Results.—Scalation characters classically used to separate *E. annulatus* from *E. ijimae* are mentioned in Table 1. Specimens from two distinct areas in the Australian region (*E. annulatus*: Australia and New Caledonia) are compared with specimens from southern Japan (*E. ijimae*: Ryukyus) for these and additional characters. Data are summarized in Tables 2–7. Data presented in

TABLE 1. Traditional scalation characters used to separate *Emydocephalus annulatus* from *E. ijimae* (after Smith 1926:26).

Characters	*E. ijimae*	*E. annulatus*
Prefrontal plates	4	2
Posterior vertebral row	enlarged	weakly or not enlarged
Cloacal shield	divided	single/sometimes divided

Tables 2 and 3 demonstrate that the traditional suite of characters used by taxonomists (Table 1) are subject to great variation with substantial overlap among the three geographic areas, species boundaries, and between sexes. However, some of the external and anatomical characters reported in Tables 4–7 indicate relevant differences between the two recognized species. The number of ventrals were significantly different ($P<0.05$) in males (Table 4) of *E. annulatus* and *E. ijimae*, but not in females (Table 5). Also number of SR–body and subcaudals in males (Table 6) and females (Table 7) show significant interspecific differences, together with the number of bands on body in males ($P<0.05$), but not in females. The same pattern was observed in VS–heart and VS–liver, where only the males show significant difference (Tables 4–5). Specimens from all three geographic areas show significant sexual dimorphism in number of subcaudals ($P<0.01$) (Tables 4–5).

Vietnamese and Taiwanese specimens of *Emydocephalus*

The only known Vietnamese specimen is an adult male collected at Dong-Naï, near the town of Voung-Taï, on 4 September 1989 (Coll. N. N. Szczerbak, n° 1912/4696 [in Kiev, Ukraine]) and reported by Dotsenko (1999). Dotsenko (1999) referred the specimen to *Emydocephalus annulatus*, but mentioned that most characters overlap between *E. annulatus* and *E. ijimae*. If we compare the data he provided on that specimen [subcaudals (30), bands on body (21), SR–body (15), weakly enlarged posterior vertebral row] with the same characters in Australian and Japanese populations, we agree that this specimen should be referred to *E. annulatus*. Other characters mentioned by Dotsenko (1999) cannot be considered as being significant differences between Australian and Japanese populations (two prefrontals and presence of a divided cloacal plate; see Tables 2-3). Moreover, when considering the data provided by Mao and Chen (1980) for Taiwanese populations, the picture of morphological variation in the genus *Emydocephalus* is even more confused: 136–145 ventrals in males (N = 8, mean = 141), 26–30 subcaudals in males (N = 7, mean = 28), 21–24 subcaudals in females (N = 4, mean = 23). All of these data are intermediate between the values for Japanese and Australian specimens. Note however that the number of Taiwanese specimens observed by Mao and Chen (1980) was limited.

Philippine specimens of *Emydocephalus*

The most closely taken head picture of a Philippine specimen from Panglao Island clearly shows two prefrontal plates (Fig. 1), and therefore using traditional characters is referrable to *E. annulatus*. However, size of posterior vertebral row and cloacal

TABLE 2. Traditional scalation characters examined on specimens (males) of *Emydocephalus ijimae* from Japan and *E. annulatus* from Australia and New Caledonia. Brackets indicate number of specimens examined with that character state. The character state "1.5" indicates that the cloacal shield is not completely divided into two distinct shields, but still has a small connection between shields.

MALES/Characters	Number	Japan	Australia	New Caledonia
Prefrontal plates	2	(12) 44%	(34) 94%	(9) 100%
	3	(8) 30%	(1) 3%	(0)
	4	(7) 26%	(1) 3%	(0)
Posterior vertebral row		enlarged	weakly enlarged or enlarged	weakly enlarged or enlarged
Cloacal shield	1	(0)	(22) 69%	(3) 20%
	1.5	(0)	(4) 12.5%	(9) 60%
	2	(27) 100%	(6) 18.5%	(3) 20%

shield shape cannot be observed in pictures available to us of the Philippine specimen. That specimen also shows the classical black and white irregular alternating body rings of *E. annulatus*.

Emydocephalus is relatively common around Panglao Island where one popular diving site is even called 'Snake Island' (e.g., Cervera Shoal, 9.483°N, 123.85°E); that area is not an island but a submerged reef located about 10 m under water. As many as ten *Emydocephalus* were seen at one site during a single dive (V. Maran, pers. comm.).

Discussion.—As can be seen from the morphological characters we have examined, there are some clear and significant differences between *Emydocephalus ijimae* from Japan and *E. annulatus* from the Australian region. Validity of both species is confirmed by our morphological examination but there are no clear external or internal characters allowing for unequivocal species attribution. Traditional characters used to separate both species exhibited considerable interspecific overlap and intraspecific variation thus preventing unequivocal separation of *E. annulatus* from *E. ijimae*. Moreover, when including published data from Taiwanese specimens, a possible latitudinal cline is evident. Future studies should include more specimens from Philippines, Vietnam, and China. This would allow workers to confirm or not whether there are two or more species in the genus *Emydocephalus*.

Our study confirms the occurrence of *Emydocephalus* in the Philippines, and adds Panglao Island to the list of known localities for these important populations. However, without any voucher specimen available from that new location, the identification of the particular species of *Emydocephalus* in the Philippines remains uncertain. According to available data, we regard those Philippine populations as phenotypically similar to southern *E. annulatus* rather than to northern *E. ijimae*. Our conclusion is based on the few characters that can be seen on the available photographs and their comparison with our data (Tables 2–7).

One additional point in favor of the existence of at least two species in the genus *Emydocephalus* is the occurrence of melanistic specimens only in Australian and New Caledonian populations of our large samples, but not in Japan. However, Kharin (1984, 2008) reported occurrence of black melanistic specimens of *E. ijimae*. Uniform black specimens in central populations (Philippine, Taiwan, and Vietnam) have not been reported but available sample sizes are insufficient to make strong conclusions. It is interesting to note, however, that New Caledonian sea kraits are represented by three species and melanism is present in only one (Lorioux et al. 2008), thus suggesting its potential value as diagnostic character.

One topic for future studies is the questionable absence or low occurrence of statistically significant differences in scale counts between females of both species whereas such differences exist in males. This pattern might reflect selection for a conservative body plan that meets requirements of both viviparity and life in a

TABLE 3. Traditional scalation characters examined on specimens (females) of *Emydocephalus ijimae* from Japan and *E. annulatus* from Australia and New Caledonia. Brackets indicate number of specimens examined with that character state. The character state "1.5" indicates that the cloacal shield is not completely divided into two distinct shields, but still has a small connection between shields.

marine environment.

Morphological and anatomical characters provide evidence that *Emydocephalus* comprises a species complex. However, the scarcity of available specimens considerably limits the scope of our work and prevents us from making strong conclusions. Future studies would benefit from the collection of DNA sequence data and estimates of molecular divergence between known populations of *Emydocephalus*. This approach (if used together with the morphological studies) could provide insight into the origin, evolution, and diversification in the genus *Emydocephalus*.

Acknowledgments.—We thank Vincent Maran for providing access to his diving observations and photographs, Charles P. Blanc (Montpellier) for translation of Dotsenko's (1999) Russian paper into French, Hidetoshi Ota (University of the Ryukyus, Japan) for the loan of Japanese specimens and Ross Sadlier and Allen E. Greer (Australian Museum, Sydney) for their help during ARR's stay at the Museum. Thanks also to Knud Højgaards Fond, Swedish Orphan International AB, and the Danish Research Council (Kulturministeriets Forskningspulje) for support during the Danish "Galathea3" expedition. The Danish Navy and scientific members on board "Vædderen" are gratefully acknowledged for their help in collecting sea snakes. The help of Rafe Brown and Van Wallach for translation is appreciated.

Rediscovery of *Abronia campbelli* (Sauria: Anguidae) from a Pine-Oak Forest in Southeastern Guatemala: Habitat Characterization, Natural History, and Conservation Status

DANIEL ARIANO-SÁNCHEZ

MONICA TORRES-ALMAZÁN
Conservation Projects Department, Zootropic, 12 Calle 1-25 Zona 10 Edificio Geminis 10 Torre Sur, Nivel 18 oficina 1801A
Ciudad de Guatemala, Guatemala
e-mail: dariano@zootropic.com

Guatemala is one of the world's biodiversity hotspots, in part the result of its complex topography and its privileged space between the Neartic and Neotropical (Campbell and Vannini 1989). Within this biota exists the arboreal lizards of the genus *Abronia*. These secretive lizards live within the pine-oak and cloud forests of northern Mesoamerica and belong to the family Anguidae (Campbell and Brodie 1999). Species of *Abronia* are known to occur from southern Tamaulipas and Guerrero, Mexico, to southern Honduras (Campbell and Frost 1993). Guatemala has been a region of diversification of this group, with 10 species, eight of them endemic. These national endemics are *A. anzuetoi*, *A. aurita*, *A. campbelli*, *A. fimbriata*, *A. frosti*, *A. gaiophantasma*, *A. meledona*, and *A. vasconselosii*. Two other species are shared with southern Mexico, *A. matudai* and *A. ochoterenai* (Acevedo 2006). With few exceptions, *Abronia* are known from few specimens, often from only the type or a few specimens from the immediate vicinity of the type locality (Campbell and Frost 1993). They spend most of their lives among epiphytes of the cloud forests and are strictly diurnal (Campbell and Frost 1993). Behavior patterns of *Abronia* have been poorly studied and field research on these species is almost nonexistent. Most of the information gathered has been for *A. vasconcelosii* in captivity (Formanowicz et al. 1990).

Conservation status of most species is uncertain, but restricted distributions and habitats disturbed or destroyed by human development have made most species of the genus among the most endangered lizards in the world (Campbell and Frost 1993). Moreover, many species of *Abronia* are threatened with immediate extinction. *Abronia campbelli* (Brodie and Savage 1993) and *A. frosti* (Campbell et al. 1998) were thought to have become extinct soon after their discovery (Campbell and Brodie 1999; Campbell and Mendelson 1998).

Abronia campbelli is a member of the subgenus *Auriculabronia* (Campbell and Frost 1993) and is characterized by having distinctive spinelike supra-auricular scales in subadults and adults, 14–16 ventral scale rows, a bright ring around the eye, 32–35 transverse ventral scale rows, variable adult dorsal coloration, usually gray, brown or yellow with black mottling forming indistinct dorsal crossbands; juvenile dorsal coloration gray-brown with 9–10 black crossbands on body and pale brown to yellow circumorbital region (Brodie and Savage 1993).

Material and methods.—Two trips were made to the vicinity of the type locality at Potrero Carrillo-La Pastoría, Jalapa, Guatemala, during 4–6 September 2009 and 21–23 October 2009. Structured interviews with local villagers were conducted to determine the possible presence of *A. campbelli* within the area. Manual searches for the species on oak trees within the area were also made to locate and capture any individuals of the species if present. For any specimen found, we took standard body measures including snout–vent length (SVL), total length (TL), and head width (H). Climatic data for the site were obtained from a meteorological station that has been recording data from La Pastoría since 1990. We analyzed the data from 1990 to 2008 to characterize the climate to which this species is exposed. We also made a geographic information system (GIS) analysis of the actual forest cover in the area using a forest coverage map of Guatemala from 2003 and SPOT satellite photos from 2008 with a resolution of 5 m^2.

Results.—The forest inhabited by *Abronia campbelli* is composed of two species of oak: *Quercus peduncularis* and *Q. brachystachys*, which are heavily covered by the bromeliad, *Tillandsia usneoides*, and other epiphytes. This forest is within a wetland surrounded by *Pinus oocarpa* pine trees that according to local villagers was heavily covered by an old growth oak forest until around 1970. Analysis of environmental data of the site provided by a weather station present at the site since the early 1990s showed that the average annual temperature is 16.91 ± 0.53ºC, maximum annual temperature is 21.76 ± 2.36ºC, minimum annual temperature is 8.41 ± 2.21ºC, annual average rainfall is 1328 ± 282 mm, and annual relative humidity is 83 ± 2.22%.

We captured 34 individuals of *A. campbelli* within the area (Fig. 1), including four juveniles. All were released after taking measurements. Average SVL was 112.3 ± 4.2 mm for males and 114.0 ± 7.5 mm for females. Head width was 26.0 ± 1.9 mm for males and 16.1 ± 2.1 mm for females. We found an average of 2.5 adult individuals per tree. From a total of 25 adult oak trees examined, 12 trees were inhabited by *A. campbelli* (48% occupancy). The specimens collected were found only in older trees of *Q. peduncularis* that had an average height of 10.68 ± 1.68 m and an average diameter at breast height (DBH) of 58.72 ± 9.43 cm, and that were covered by thick masses of epiphytic growth.

Although *Abronia campbelli* is not extinct, it is in critical danger of extinction if strong conservation measures are not taken. There are only 406 standing *Quercus* trees remaining at the type locality according to the GIS analysis. The area is severely fragmented consisting mainly of isolated old oak trees with an average distance between them of 55 ± 18 m (Fig. 2).

Discussion.—Environmental data gathered at the site are similar to the weather conditions we have seen for other species such as *A. vasconselosii*. The wetland where the oak forest was reported in the past still persists and makes this area very humid, contrasting with the suggestions of Brodie and Savage (1993)

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

that this species inhabits the driest forest for any *Abronia* species.

Taking into account that we found an average of 2.5 individuals per tree and that the occupancy average of the trees was of 48%, we estimate that in the area there are still around 487 adult individuals remaining in a highly fragmented habitat. The main action that has been identified in the past as causing this high rate of deforestation at the type locality is logging for firewood (Brodie and Savage 1993), but our interviews with local villagers suggest that presently, the main action that is causing this dramatic deforestation is logging for raising cattle

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 2. Isolated oak tree where three specimens of *Abronia campbelli* were found at Potrero Carrillo-La Pastoría, Jalapa, Guatemala.

in the area. This shows the urgent need for habitat restoration at Potrero Carrillo-La Pastoria, Jalapa, Guatemala, as a way to increase connectivity among the last standing oak trees that remain at the site. A strong reforestation program to increase connectivity using oaks and some kind of fast growing tree from native species such as *Liquidambar styraciflua*, *Alnus* spp. or *Leucaena diversifolia* may be used. *Quercus* species need some kind of shadow to regenerate well (Dey et al. 2009). We suggest that the fast growing trees planted as part of the reforestation program can be covered with *Tillandsia usneoides* which is the main microhabitat of *A. campbelli* at the site. This will help increase the connectivity within the remaining oak trees and also promote natural regeneration and growth of the planted oak trees. Another conservation measure we suggest is joining the top of the remaining oak trees in the area with ropes that can be covered with thick masses of *Tillandsia usneoides* so they may function as artificial corridors among trees to increase genetic flow within the population. Also, random manual translocation of female individuals between the remaining trees may be useful in increasing the genetic flow within the population.

Another important threat is that the remaining individuals of *A. campbelli* in the wild now are under pressure from smugglers who trade them in foreign countries for the pet trade and collectors. At the time of our first visit in September 2009 we noticed the presence of foreigners at the type locality that were looking for the lizards. Unfortunately, at that time we did not have enough information to realize what these people were doing at the site. Additional information has led us to believe that these people were smugglers that were looking for *A. campbelli* for commercial trade in Europe. We learned from interviews with local villagers that smugglers have taken at least five individuals of *A. campbelli* with them. The destination country to which the lizards were taken is unknown. We suggest that an inclusion of the genus *Abronia* under CITES could be a management tool that can help in controlling and reducing the trade in these species. We have also secured six pairs of this species for a conservation captive breeding program held at Zootropic Herpetarium located in Guatemala City.

The inhabitants refer to *A. campbelli* as "*escorpión*," and believe it is a highly venomous animal. In the past, if they encountered these lizards, they would kill them. Taking into account such threats, we have taken steps to increase public awareness about the relevance of conservation of this species and to correct the misconceptions that exist about this species among farmers and local villagers. More recently, we have also begun actions with landowners to protect and restore the forest remnants at the type locality

Acknowledgments.—For financial support we thank Rick Hudson and the Fort Worth Zoo's *Abronia* Conservation Fund with the following contributors: Nashville Zoo, Sedgwick County Zoo, Oklahoma City Zoo, San Diego Zoo, Phoenix Zoo, and the Detroit Zoological Institute. Conservation actions to preserve this species and its habitat are financially supported by Zoo Atlanta, International Reptile Conservation Foundation, The Humane Society International, and the U.S. Department of State. We thank our field assistants L. Nájera and O. Nájera, and our colleagues at Zootropic, C. Beza, A. Urbina, and L. Meléndez, who helped with many aspects of data collection. Special thanks to E. D. Brodie, Jr. and an anonymous reviewer whose comments have improved the present paper. CONAP provided permits for conducting this research

(permit no. 050/2009).

Cover Images for *Herpetological Review*

We are looking for photographic images to appear on future covers of *HR*. To be considered, preferred images should have the following qualities:

- Should be technically superior photographs (e.g., composition, lighting, etc., should be excellent; subject must be in focus).
- Should be taken in vertical format, or, if in landscape (horizontal) format, permit cropping to achieve a vertical orientation.
- Should be based on film or digital media; if the latter, the native resolution must be sufficiently high to permit cropping and/or enlargement to print publication quality.
- Preference will be given to images that depict poorly known species. These could include recently described taxa or species for which a color illustration has never been published.
- Preference will be given to images that communicate some aspect of the biology of the organism (e.g., predation, feeding, courtship, crypsis).

Images for consideration should be submitted as low-resolution jpg or pdf files. Do not send full resolution images via email unless requested to do so. All submissions or questions should be directed to the Editor (HerpReview@gmail.com).

That museum collections are biased in various ways comes as no surprise to anyone familiar with collections-based research. But the specific nature of biases and their implications for various research questions often are things that investigators learn by practice or experience. In 2004, we offered a new undergraduate non-science majors course on Natural History Museum Science at The University of Texas at Austin. The course was open to all first- and second-year students, and attracted many students from majors outside of the natural sciences. The course curriculum included touring the many natural history collections archived at The University of Texas at Austin, as well as direct field and laboratory experience in surveying, collecting, and curating specimens. During the first semester the course was offered, it became clear that students needed additional instruction on the nature of museum collections, the relevance of voucher-based collections, and the need for and importance of maintenance and growth of collections. These additional areas of instruction were required to address student concerns that emerged during collections tours when, for example, they confronted for the first time thousands of preserved specimens. The understandable and almost ubiquitous question of "why would you need more?" focused our attention on the need to specifically address temporal bias present in all historical collections. As long-term collectors we suspected, but did not ourselves fully appreciate, the severe temporal biases present in our own collections.

In order to address these concerns, we sought to develop a discovery-based project for the laboratory portion of the course. We developed a data set that would allow students to explore and understand the nature of geographic and temporal biases in collections, and to begin to assess the implications of those biases for interpreting data derived from historical collections. In reviewing the museum and collections literature, we were unable to find a similar study using a comparable data set in the classroom; the results of our discovery-based project are of sufficient interest to the herpetological community that we share them here.

Methods

Collections Records and Taxon Selection.—We exemplified the

nature of geographic and temporal bias using a data set derived from collections records of the small colubrid Common Ground Snake, *Sonora semiannulata*. As a logistical convenience, our initial compilation of collections records was derived from seven representative collections within the state of Texas. We compared initial results derived from that limited data set with distribution maps presented by Werler and Dixon (2000) and found that overall distribution data were comparable. Consequently, our survey was taken as sufficient for the goals we had in mind for students.

Distribution records were derived from Angelo State Natural History Collections (ASNHC), Sul Ross State University (SRSU), The Texas Cooperative Wildlife Collection (Texas A&M, TCWC), Texas Natural History Collections (The University of Texas at Austin, THNC; also includes the former Texas Tech University collections), The University of Texas at Arlington Amphibian and Reptile Diversity Research Center (UTA), The University of Texas at El Paso Laboratory for Environmental Biology (UTEP), and the American Museum of Natural History (AMNH; now housing the collections of Texas A&M at Kingsville). We requested locality information and date of collection for all specimens catalogued in their collections under the names *S. semiannulata* and its former designation *S. episcopa*.

We chose *S. semiannulata* as an exemplar because it is mapped as being widely distributed within Texas, is readily identifiable, is not threatened or endangered within the state, and is small enough that it is not inconvenient to collect or store. For these reasons, there is no obvious disincentive to serendipitous field collections (i.e., it is easy to identify, preserve in the field, and transport back to the museum). We retrieved records for 1737 specimens with collecting dates ranging from 1923 through 2004. For plotting purposes, multiple specimens collected from a single geographic location on the same date were treated as a single collection record. If additional specimens were collected from the same place in a subsequent year, that constituted an additional collection record. When defined in this way, a total of 843 collection records were recorded.

Data Depiction.—Most students are introduced to thinking about geographic distribution of taxa through the use of field guides. Traditional field guides depict geographic distribution through the use of shaded distribution maps (e.g., Conant and Collins 1998; Dixon and Werler 2005), in part as a result of space limitations associated with publication of such geographically expansive works. Shaded distribution maps tend to overestimate the area inhabited by a species because this method broadly fills in the gaps between single point localities of specimens. Some more recent distribution maps available to the public utilize dot-distribution format, based on data ultimately derived from museum collections records. The resolution presented is often coarse (e.g., presented at the county level by Dixon 2000), but the excellent maps in Ralph Axtell's Interpretive Atlas of Texas Lizards (e.g., Axtell 1987, 2005) were also adopted by Werler and Dixon (2000) in their major reference on Texas snakes. The conservative presentation of dot distribution maps more accurately defines the known distribution of a species, rather than its inferred presence at suitable habitats within a shaded distribution.

We plotted collection records of *Sonora semiannulata* as dot-distribution data on a base-map of Texas, with county boundaries visible. Few records were georeferenced, so all localities were plotted by eye using a gazetteer. We provided visual representation of date-of-collection data by color-coding collection records by decade of collection. For the most recent 15 years of our records (1990–2004), we color-coded records in five-year increments to provide a more refined assessment of modern collecting practices (Fig. 1). As part of a class exercise, students are asked to identify biases in collection records by manipulating the data set to view records from particular institutions, or all records from a given temporal interval, or a combination of the two.

Results

Spatial Distribution.—Not surprisingly, spatial distribution of collection records differed for each museum collection, and each collection reflected geographic biases in their holdings. As expected, much of this bias was centered on proximity of the institution to concentrations of collection records (e.g., the UTEP collection contains the vast majority of records from El Paso Co; Fig. 1A). We were surprised to note that even the smallest collections included unique county records for the species (AMNH N = 28 specimens, provided unique record for Maverick Co.; Fig 1B; SRSU N = 54 specimens, provided unique record for Oldham Co.; Fig. 1C). These observations emphasize the importance of maximal collection sampling to refine geographic distribution data, even for taxa that seemingly are well-represented in collections. Within our data set, we identified several counties for which no records of *Sonora* were recorded, but which are surrounded by counties for which there are records. This obviously calls attention to areas where future surveys might profitably be conducted, but in some cases also reveals the limitations of our logistically convenient self-restriction to survey only seven Texas collections; some of our 'empty' counties (e.g., Callahan, Fisher, Schleicher counties) do have records depicted by Werler and Dixon (2000), but others do not (e.g., Haskell Co., shaded on Fig. 1).

Our data set also displays outlying collection records, especially in eastern counties within the state. These records form a discontinuous distribution with central and western counties (a discontinuity also reflected on the map presented by Werler and Dixon, 2000), and suggest either lack of collection activities in intervening counties, or relict or isolated populations of the snake in eastern counties.

One notable spatial bias is the collection of specimens from roadways in Texas. Collection localities clearly situated along roadways include those from Texas State Highway 118 in Brewster County (Fig. 1D), Farm to Market Road 170 in Brewster and Presidio counties (Fig. 1E), and Ranch to Market Road 473 east of Comfort in Kendall County (Fig. 1F). Following the description of techniques and potentialities of road driving as a source of specimens (Klauber 1939), the practice became more prevalent, was established in Texas as early as the 1940s (e.g., Ranch to Market Road 473), and resulted in significant collection records housed in the institutions we surveyed.

Temporal Patterns in Collection Data.—The vast majority of collection records represent specimens that were collected after

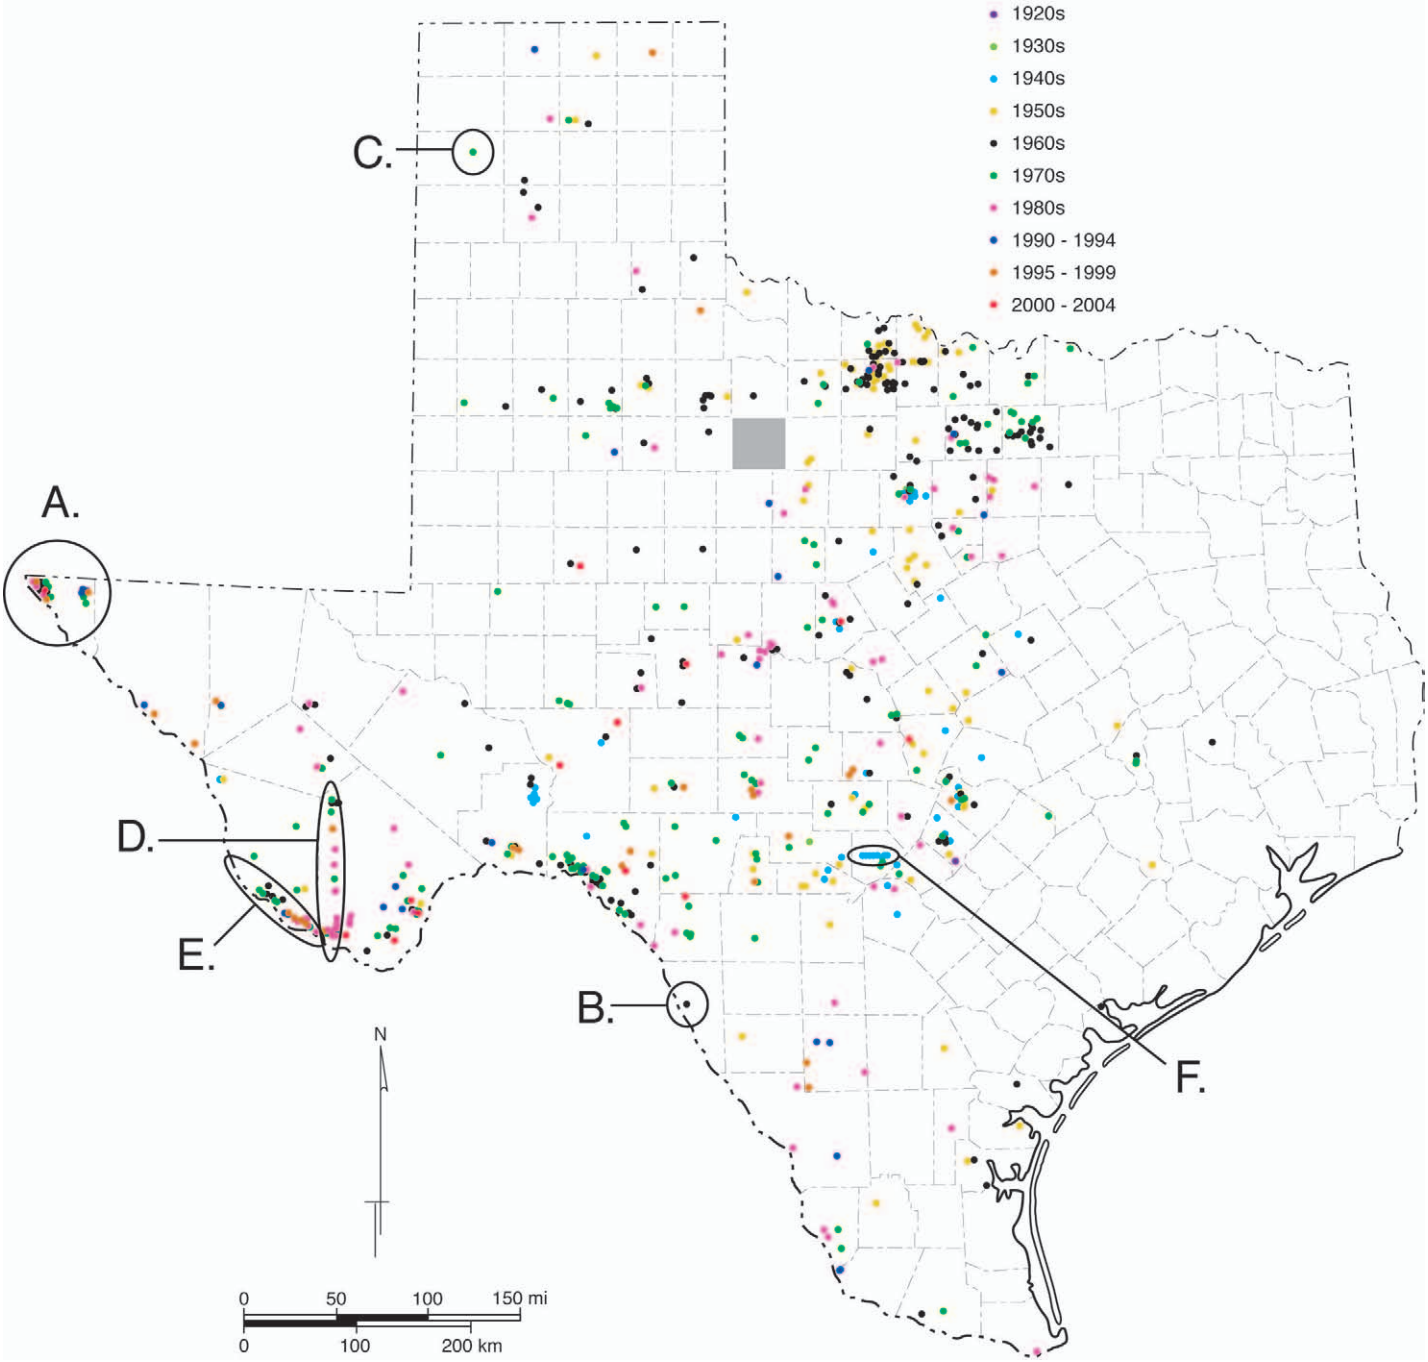

FIG. 1. Spatial and temporal distribution of *Sonora semiannulata* in Texas from all collections we surveyed. Dot distribution data are color-coded by decade of collection, with 1990–2004 broken into five-year intervals. Haskell County (shaded, in the north-central part of the state), represents a county from which no records are known, although surrounding counties all have vouchered records. A. El Paso County records; all but two of these are housed in the UTEP collection. B. Unique county record for Maverick County from AMNH collection. C. Unique county record for Oldham County from SRSU collection. D. Collection records along Texas State Highway 118 in Brewster County. E. Collection records along Farm to Market Road 170 in Brewster and Presidio counties. F. Collection records along Ranch to Market Road 473 in Kendall County.

1939 and prior to 1980. A total of only seven specimens are recorded for the 1920s and 1930s combined. Significant collecting began in the 1940s (71 collection records), but was concentrated in the central portion of the state and confined to the only three collections in existence at the time (AMNH, TCWC, and TNHC). In the 1950s, 140 collection records document expanded geographic coverage, the first records from the Panhandle region, significant collections in the vicinity of Wichita Falls and from south Texas counties, and the first collections from eastern 'outlier' counties. In the 1960s, new collections-building efforts at ASNHC, SRSU, and UTEP (coinciding with their establishment in that decade) and continued collections from TNHC and TCWC yielded 254 collections records. Those provide for the first time collections from within a single decade that yield a perspective on distribution that essentially circumscribes what we see as the 'modern' distribution of the species (e.g., easternmost record

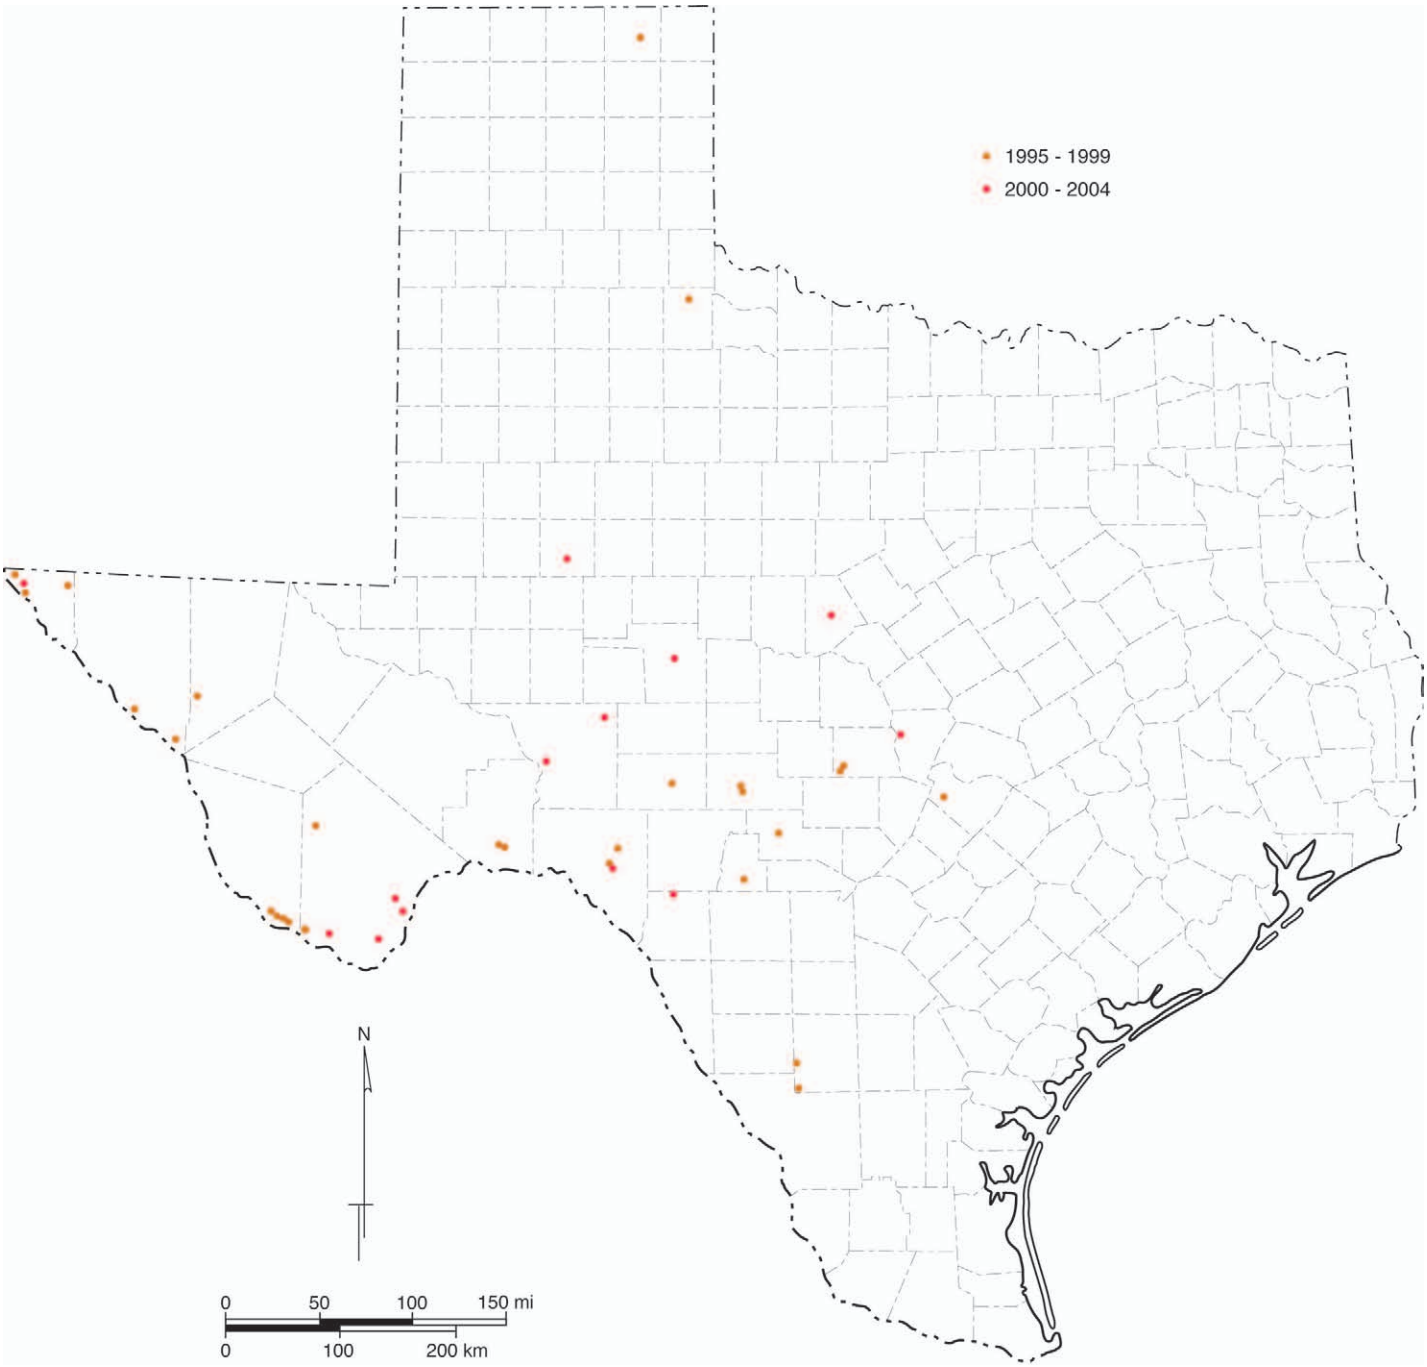

FIG. 2. The actual modern spatial distribution of *Sonora semiannulata* in Texas, based on vouchered collection records taken between 1995 and 2004, inclusive.

documented, West Texas expansion). Records from the 1970s (N = 181) also reflect collections from across the perceived range; SRSU records come predominantly from within this decade, but are concentrated in the Trans-Pecos region. Beginning in the 1980s, collection records decline (N = 111), and do not regain the prominence of earlier decades; the 1990s yield only 63 collection records and there are only 16 records from 2000 through 2004. The paucity of truly modern collections (those from 1995 to 2004) relative to the total data set is dramatically demonstrated when depicted on the base map (Fig. 2). Collections data summarized by decade, housing institution, and collection founding date are provided in Table 1.

DISCUSSION

Our data set affords us the opportunity to discuss with our students many of the challenges scientists face as they decided how (or whether) to continue building voucher-based systematic collections. At face value the seven major Texas natural history collections yield, in the aggregate, a reasonable perspective on the distribution of *Sonora semiannulata*, as it is reflected in shaded or dot-distribution maps in standard field guides (e.g., Conant and Collins 1998; Werler and Dixon 2000). When temporal data are considered, it is clear that we have a reasonable understanding of the historical distribution of the species as it existed in the 1960s and 1970s, but existing collections fail to document a 'modern'

TABLE 1. Number of *Sonora semiannulata* localities from seven institutional collections organized by year of collection.

Institution (year collection founded)	1920–29	1930–39	1940–49	1950–59	1960–69	1970–79	1980–89	1990–94	1995–99	2000–04	Total
ASNHC (~1967)	0	0	0	0	78	20	0	2	3	4	107
AMNH (1869)	3	2	5	2	4	0	1	0	0	0	17
SRSU (~1963)	0	0	0	1	6	29	1	2	0	1	39
TCWC (1936)	0	2	14	101	86	52	46	6	2	7	316
TNHC (1946)	0	0	52	34	44	36	0	1	10	1	178
UTA (1959)	0	0	0	2	27	27	43	11	7	0	117

Total	3	4	71	140	254	181	111	29	34	16	843

distribution, if we take 'modern' to be the last two decades or less. Indeed, many historical records provide insights into the existence of past populations that are no longer viable because land-use change has modified native habitats to suit the needs of geographically expanding human populations (e.g., Krysko and Smith 2005). The specific reasons for declines in collections of *Sonora* are not known, but probably are multifaceted and can be conceptualized as reflecting both operational restrictions on voucher-based collecting as well as shifting attitudes towards collecting among scientists, regulators, and the public. These are fertile grounds for discussion with students.

Attitudes of scientists are shaped by their training, experience, and the exigencies of the day. Over the last decade, we have noticed that student training (undergraduate and graduate) appears to be increasingly centered on taxonomic specialization (see also Alberch 1993). The current decline in the teaching and training of students in natural history (Schmidly 2005) will likely influence whether current and future students choose to collect and contribute to natural history collections. Many herpetology classes no longer require student collections of reptiles and amphibians, further reducing the continued sampling of regional herpetofauna. The ascendancy of molecular biology has yielded vast new insights into biology, but in many cases comes with a concomitant decrease in voucher-based field work, or at least in collecting broadly beyond a focal taxon. To this end, we know of collectors who focus on increasing museum holdings of blood and tissue samples but fail to voucher a majority of those animals sampled. While such collecting endeavors may not reflect the written policy at any one institution, similar efforts may become more commonplace.

Many institutions also face increasing limitations in available funding and space to house existing collections, much less to expand them (Dalton 2003, 2007; Raven 2003). In some cases, this may lead to a cessation or decline in collections activities, or to more focused, less general collecting practices (e.g., Antunes and Vicente 2004). Reduced funding for travel may focus remaining collecting efforts towards "unique" areas of high diversity (e.g., the Big Bend of Texas) rather than allow for general, repeated collections near the home institution. More importantly, the increasingly complicated laws regulating the study, collection, and transport of specimens have resulted in long and frustrating experiences for many scientists in obtaining permits to conduct voucher-based collections (reviewed by Duellman 1999). Ironically, conservation biologists now also must confront the reality that results of their work can be used to restrict access by scientists to their research organisms, while leaving unchanged (or unregulated) access of other individuals, corporations, or special interest groups (e.g., Campbell and Frost 1993).

In Texas this general problem with permits was exacerbated recently when additional collecting restrictions were erected by the Texas Legislature based on the perceived threat of commercial over-collection and public safety issues. Texas House Bill 12 became law on 15 June 2007 along with its Section 44 (formerly Senate Bill 2414). That law prohibits the collection of any live wildlife specimens from public roads or rights-of-way (dead animals can be salvaged under state-issued salvage permits). The law does not curtail collecting activities by museum or scientific personnel collecting with an amended scientific collecting permit, but it will significantly curtail deposition of specimens serendipitously collected by non-specialists (e.g., birders, or members of the public who previously could collect legally under a Texas hunting license; see also Silvertown 2009). This has special relevance in Texas, a state in which approximately 96% of the land is held in private hands (Schmidly 2002), and often is inaccessible for scientific collection.

Although they are an improvement over shaded or county-level distribution maps, standard dot-distribution maps continue to mask the inadequacy of our actual understanding of the current geographic distribution of *Sonora semiannulata* in Texas. Although we did not test specifically the general applicability of this conclusion, we suspect and fear that it applies broadly to virtually all systematic collections, and is generalizable across the globe, and not just a deficiency of Texas collections. This is a particularly important consideration in light of extensive land-use changes in Texas and elsewhere in the last 50 years and the impacts they have on the distribution of native fauna (Schmidly 2002; Shaffer et al. 1998; Skelly et al. 2003).

An emerging reliance on museum collections for reconstruction of historical distributions of species (Elith et al. 2006; Frey 2009; O'Connell et al. 2005; Raxworthy et al. 2003) must be tempered by an understanding of the limitations and biases associated with such collections. An increased appreciation of temporal bias in collections is essential if policy and management decisions are to be based on current knowledge. Collection practices through time and across space were not and are not uniform, a point most of our students fail to grasp until they work with our data set. It is inappropriate to make assumptions of uniformity when

assessing historical records for data on past distributions of fauna or the environmental conditions under which they lived (Fagan et al. 2005), or for making predictive assessments of the likely future impacts of current policies (Pyron et al. 2008; Rodda et al. 2009). Further complications arise when species distributions are estimated from web-based biodiversity databases derived from incidental, anecdotal, or unvouchered observational data, rather than vouchered museum material. Results from extrapolations of these data can be misleading, if not spurious (Lozier et al. 2009; McKelvey et al. 2008). The recent HerpNET database (HerpNET.org) represents a collaborative effort of more than fifty institutions to provide a single portal for herpetological collection holdings, most of which are georeferenced. The existence of pooled data sources such as this now make it easier to compile and rapidly visualize temporal distribution data for many taxa (e.g., MaNIS for mammals, ORNIS for birds, FishNet for fish, OdonataCentral for odonate insects).

The value of historical collections as data sources for answering questions about past distributions and environmental or ecological conditions is well-established (e.g., Graham et al. 2004; Grinnell, 1910; Moritz et al. 2008; Myers et al. 2009; Raxworthy et al. 2008). In surveying our colleagues and students about opinions regarding the potential uses and value of voucher-based collections, we regularly encounter expectations that collections should provide baseline data to help us understand trends in taxon distributions through time, as well as alterations in population densities, demographics, and community structure, and the response of organisms to global change issues on local and wide geographic scales. We often expect collections to provide information that permits administrators to make adequate and informed management decisions, and to assess historic patterns of the emergence and significance of chemical pollutants, parasites, and other environmental factors. We also expect collections to serve as a data archive for future generations to assess similar issues about changes to fauna and flora that we are now experiencing, and to help answer questions we have not yet thought to ask. It is clear that many such popular expectations of data-yield from collections may not be attainable from existing collections, and current collecting practices are almost certainly failing the needs of our future colleagues.

With global change issues so prominently represented in the minds and daily lives of our students and ourselves, it is ironic that we are living through times in which voucher-based collections have declined. We echo the cry of the great museologist Joseph Grinnell (1915) to 'conserve the collector.' It has fallen on our generation to assume the responsibility to provide a detailed record of biotic responses to global change. But the serendipitous nature of both temporal and spatial data associated with many recent museum accessions confound modern students' understanding of museum collections and will frustrate efforts of future generations to extract meaningful patterns from those data. The general dearth of focused, systematic collection efforts (Boundy and Burbrink 1998; Hoberg et al. 2009; Shaffer et al. 1998; Winkler 1996) must be adequately addressed if we are not to be judged as having failed to meet our responsibility.

Long-term monitoring and responsible collection of voucher specimens, combined with a renewed emphasis on adequate field notes and online (and archived) databases, will help to establish a reliable data set on changing distributions of Texas fauna for future generations. Although not specifically addressed in our study, the issues we discuss for *Sonora* are likely to be exacerbated for endangered or threatened species whose conservation status may serve as an increasingly potent disincentive for voucher-based collections (Roberts and Solow 2008). Unfortunately, these are also among the species for which future generations will be most eager to find reliable data.

Acknowledgments.—We are grateful for the assistance of our colleagues at various institutions who helped us with data queries and provided collections records for specimens under their care. These include Kelly McCoy (ASNHC), Linda Ford, Darrel Frost, David Kizirian (AMNH), Jim Mueller, Steven Platt, James Scudday (SRSU), James Dixon, Lee Fitzgerald, Toby Hibbitts, Kathryn Vaughan (TCWC), Jonathan Campbell, Carl Franklin (UTA), Carl Lieb, and Robert Webb (UTEP). Additionally, we benefited greatly from conversations on the topic of voucher-based collections with Dean Hendrickson, Ric How, Brad Maryan, Jim Mead, Jim Parham, and Greg Pauly. Jeffrey Horowitz provided the base map of Texas, and Kyoko Kishi and Egan Jones assisted with data depiction and logistical support. Geraldine E. Swartz reviewed previous versions of the manuscript. Financial support for this project was provided by the Jackson School of Geosciences at the University of Texas at Austin.

On the Alleged Rediscovery of the Type Specimen of *Phrynosoma ornatum* Girard 1858

RICHARD R. MONTANUCCI
Department of Biological Sciences, Clemson University
Clemson, South Carolina 29634-0314 USA
e-mail: RRMNT@clemson.edu

During the preparation of a taxonomic revision of the *Phrynosoma douglasii* (Iguania: Phrynosomatidae) species complex, I had the opportunity to examine University of Michigan Museum of Zoology (UMMZ) 3849, which according to Banta (1970), is the previously missing holotype of *Phrynosoma ornatum* Girard (1858a, b). My initial review of Banta's account and conclusions led me to suspect that he was in error. A summary of the historical facts and my conclusions after further investigation of this case are presented below. Details concerning Banta's search for the missing type specimen are taken directly from Banta (1970). Museum acronyms follow Leviton et al. (1985).

Girard (1858a, b) described several species allied to *Phrynosoma douglasii*, under his subgenus *Tapaya*, including *Tapaya brevirostris*, *T. hernandesi*, and *T. ornatissima*. No descriptive account is given for *Phrynosoma ornatum*; however, in Girard's atlas (Girard 1858b: Plate 21, Figs. 1–5) this taxon is illustrated and named in the caption from material collected near Salt Lake, Utah. As explained by Stejneger (1919), Girard was uncertain about the validity of *Phrynosoma ornatum* and while his text (Girard 1858a) was in press, he decided to place the name in the synonymy of *T. douglasii*. However, Girard's decision came too late to alter the caption for the illustrations in Plate 21. Stejneger (1919) regarded the name in the caption and associated illustrations as a valid description. He expressed the opinion that *P. ornatum* was not related to *P. hernandesi*, but was sufficiently distinct from *P. douglasii* to be treated as a subspecies. He therefore revived the name and applied it to the

short-horned lizard populations in the Salt Lake Valley of Utah. Stejneger's taxonomic treatment of this form was followed by Smith (1946) and Reeve (1952).

The type specimen of *Phrynosoma ornatum* was listed by Reeve (1952:847) as unknown. Nearly a decade later, Benjamin H. Banta initiated a search to determine whether the type material was still extant. Early in his investigation, Banta reviewed the list of United States National Museum (USNM) specimens compiled by Cope (1900:414) and noticed a specimen (USNM 233) collected by Captain Stansbury near Salt Lake, Utah. Girard (1852:363) mentioned that the specimen figured in his monographic essay on *Phrynosoma* was from the Valley of the Great Salt Lake, where it had been collected by Captain Stansbury. In his later taxonomic work, Girard (1858a:398) stated under the heading *Tapaya douglassi* [sic] that "… two species may yet be confounded under this heading, one peculiar to the Northwest Coast, the other to the Great Salt Lake Basin. *The specimen figured* [emphasis added] belongs to the latter region." With this information, Banta (1970) assumed that only one specimen, namely USNM 233, had been available to Girard at the time his illustrations were prepared, and therefore USNM 233 must be the type specimen.

In an attempt to locate USNM 233, Banta wrote to Doris M. Cochran, then curator of the Division of Reptiles and Amphibians at the USNM (= National Museum of Natural History). He learned from her that USNM 233 had been sent to a museum in Chicago "in the early days." Banta reasoned that this explained why the specimen had not been listed by Cochran (1961) in the USNM type collection. Banta was already dubious that the type was in the Field Museum of Natural History (FMNH) because he had visited that institution in 1961 and had compiled substantial information on their holdings of Great Basin material. After receiving Cochran's letter, Banta wrote to W. J. Beecher, Director of the Chicago Academy of Sciences (CA), to inquire about USNM 233. Beecher had no record of the specimen and forwarded Banta's letter to Robert C. Inger at the FMNH, who only confirmed Banta's belief that the specimen was not located there. In a further effort to find the missing specimen, Banta enlarged his concept of the Chicago area to encompass the Great Lakes region, thereby including the University of Michigan as a possible repository.

In the spring of 1962, Banta received a series of specimens of *Phrynosoma douglasii* on loan from the UMMZ. Included in this shipment was UMMZ 3849 listed from Salt Lake, Utah. Upon further inquiry, Banta learned that this specimen had been received from the USNM in 1859. Banta compared UMMZ 3849 with the illustrations in Girard's atlas (Girard 1858b) and found them to be "close in many details" (Banta 1970:203). He concluded that UMMZ 3849 must be the missing type. However, there was a discrepancy concerning the collector of the specimen. According to Tappan (1861), the catalogue of the "Trowbridge collection" lists Lt. Beckwith, not Captain Stansbury as the collector of "*Tapaya brevirostris*" from Salt Lake, Utah. But, Banta dismissed this discrepancy as a typographical error.

I examined UMMZ 3849 and noted inconsistencies between it and Girard's illustrations, including the dorsal and gular pattern and arrangement of head scales. Furthermore, in my subsequent review of Girard's (1858a, b) text and figure captions, I discovered that the allusion to the use of a single specimen for the illustrations in Plate 21 was a misstatement. In fact, two specimens had been used, which constitute syntypes for the name *Phrynosoma ornatum*. An adult female is illustrated in Figs. 1–4, depicting the lateral, dorsal, and ventral views of the entire animal and a frontal view of the head, respectively. Figure 5 illustrates the thighs and postcloacal region of the male sex (Girard 1858a:399). UMMZ 3849 is an adult male and therefore could not have been used for Figs. 1–4, although it might have been used for Fig. 5. Banta, apparently failing to carefully read the figure captions in Girard's text, had been misled into thinking that only a male specimen had been available to Girard for the preparation of his illustrations. Furthermore, UMMZ 3849 could not have been used to prepare the illustration of the postcloacal region in Girard's (1858b) atlas (Plate 21, Fig. 5). Figure 5 shows a unique arrangement of enlarged scales, and a comparison of the specimen with the illustration reveals notable differences (Fig. 1). Hence it was not the specimen used for Girard's illustration.

In an effort to identify the male syntype, I next examined other USNM specimens collected from the Salt Lake Valley of Utah. Cope (1900:414) also lists USNM 234 (three specimens) secured by J. Bowman in the Salt Lake Valley. Two of these specimens have been renumbered as USNM 293246–47. Because of the fragile condition of all three specimens, they could not be shipped, but I was able to examine photographs. The two renumbered specimens are small subadults, and do not resemble the female specimen illustrated in Figs. 1–4. However, the specimen retaining the original number (USNM 234) is an adult female that is remarkably similar to the specimen in Figs. 1–4 of Girard's (1858b) Plate 21. The dorsal integument of the specimen, however, is displaced posteriorly and to the anatomical left, with abrasion resulting in some loss of pattern. Nevertheless, the dorsal pattern is similar to Girard's illustration in terms of the number, relative positions, and shapes of the dorsal spots (Fig. 2A). The specimen also has remnants of dark suffusion in the gular region as seen in Girard's (1858b) figure of the ventral aspect (Fig. 2B). There is also a unique arrangement of scales in the frontal area of USNM 234, similar to that seen in Girard's (1858b) illustration of the dorsal view. There are two enlarged frontals diverging slightly from one another. Posteriorly, there are two smaller scales in contact with the paired frontals, followed by three contacting scales (Fig. 2C). The scales in other areas of the head of USNM 234 differ from the illustration. This could be attributed to artistic license because the figure is that of the entire animal, not of the head alone. In support of this notion, other areas of this illustration appear to be stylized. Taking these considerations into account, USNM 234 could be the female specimen used in the preparation of Figs. 1–4 in Plate 21 of Girard's (1858b) atlas.

If USNM 234 is not the specimen figured in Girard's atlas, then it is possible that a specimen from a series collected by Lt. Beckwith (USNM 229–32) was used for the illustrations. This series of six specimens, two pairs each sharing the same number (see Cope 1900:414), was collected from the "Utah Basin" (an alternative early name for the Great Salt Lake Valley; see Stejneger 1919). According to Kenneth Tighe, the specimens are now lost and the lack of species cards indicates that they were not in the USNM collections when the card files were created in the early 20th century. The specimens may have been on loan to E. D.

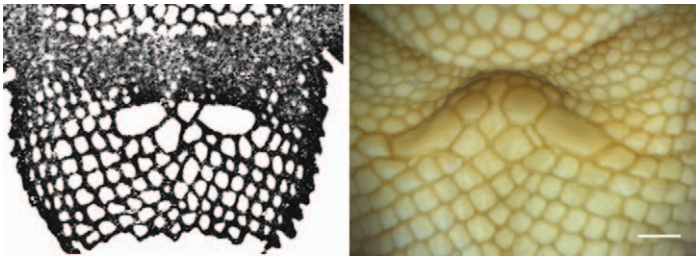

FIG. 1. Differences between the arrangement of postcloacal scales of UMMZ 3849 (right) and Girard's (1858b, Fig. 5, Plate 21) illustration of the male syntype of *Phrynosoma ornatum* (left). Bar = 1 mm.

Cope and part of the material presumed to have been lost after his death in 1897.

Banta (1970) argued that UMMZ 3849 had not only been used for the illustrations in Girard's (1858) work, but also for the figures in his earlier monographic essay (Girard 1852). As mentioned previously, the specimen depicted in Girard (1852; Figs. 6–10) with the caption "*Phrynosoma douglassii*" [sic], was obtained by Captain Stansbury in the Great Salt Lake region (Girard 1852:363). There is no doubt that the illustrated specimen is USNM 233 (presumably a male, as Girard mentioned the conspicuous femoral pores); no other USNM specimen of this taxon from the Salt Lake region was associated with Stansbury's name (see Cope 1900:414; Smithsonian collection database). But all evidence indicates that UMMZ 3849 is not USNM 233, and hence is not the specimen figured in Girard (1852). UMMZ 3849 differs notably from the illustrated specimen in general hue, dorsal pattern, degree of spinosity, and in total length: UMMZ 3849 is ~99 mm; Girard (1852) stated 3.5 inches (~87.5 mm) for the figured specimen. Moreover, the Michigan catalog entry for UMMZ 3849 indicates that its original number was USNM 207, not USNM 233. A check of the ledger records at USNM also confirmed that UMMZ 3849 was originally USNM 207 (one of three specimens, two apparently lost), collected by Lt. E. G. Beckwith. It is unclear whether Banta attempted to retrieve this information from these institutions.

The postcloacal area of USNM 233 is depicted in Fig. 10 of Girard (1852), but as rendered, the enlarged postcloacal scales are obscured. Hence, a comparison with Fig. 5 in Plate 21 of Girard's (1858b) atlas is inconclusive. There are differences in other details, which suggest that the two illustrations were based on different specimens (see Banta 1970, Fig. 4), but the differences can also be attributed to artistic style. Therefore, the question as to whether USNM 233 was the male syntype of *P. ornatum* remains unanswered.

I examined a copy of the original ledger with the entry for USNM 233, which shows the notation "1 Chicago," and hence confirms the information Cochran had sent to Banta. However, in response to my inquiry about this specimen, the personnel at the FMNH and at CA (which also includes the collections from Northwestern University) were again unable to locate or find any record of USNM 233. There is reason to believe this specimen was sent to CA. Robert Kennicott, a protégé of USNM's Spencer Baird, helped establish the CA and build its natural history collections from 1857 to 1864 (Vasile 1994). A number of specimen exchanges between the USNM and CA occurred before the 1870s (S. Gotte, pers. comm.). Hence, it is likely that USNM

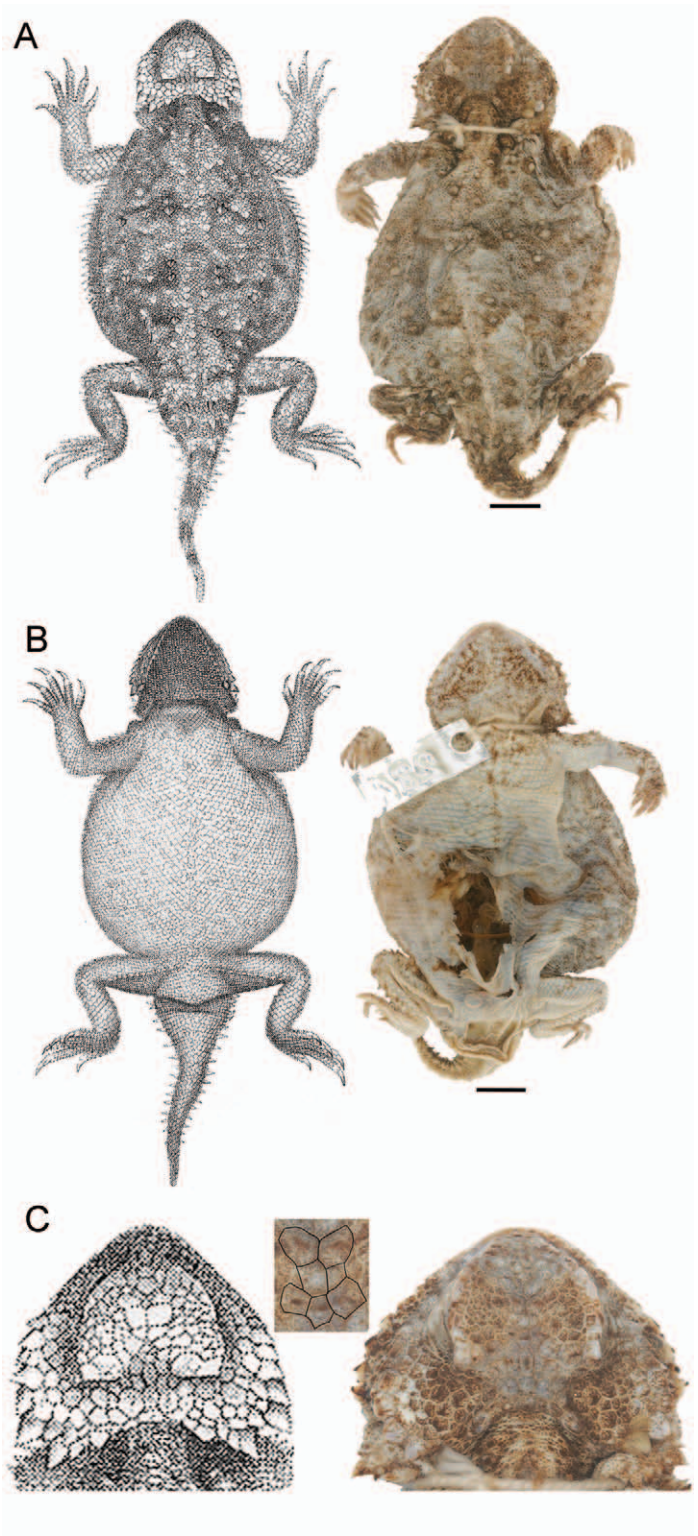

FIG. 2. Comparisons between USNM 234 and Girard's (1858b, Plate 21) illustrations from his atlas. A, dorsal view; B, ventral view; and C, detailed comparison of the head with enlarged scales outlined (see text). Bar = 1 cm.

233 was lost in the Great Chicago Fire of 1871. Although Cope (1900:414) listed the specimen as in the USNM collection for the year ending 30 June 1898, this could be an error as many other errors have been detected in that publication (S. Gotte, pers. comm.).

I also searched in the Academy of Natural Sciences of Philadelphia (ANSP) for the missing type material of *Phrynosoma ornatum*. I examined a series of nine adult specimens (ANSP 8724, 8727–28, 8731–32, 8736–38, 8740), all lacking collector or locality data, and compared them with Girard's (1858b) illustrations (Figs. 1–5 of Plate 21). However, none of the specimens shows any resemblance to the illustrated syntypes or to USNM 233 depicted in Figs. 6–10 of Girard (1852).

In summary, the illustrations of *Phrynosoma ornatum* in Plate 21 of Girard's (1858b) atlas are based on two syntypes, female and male, not on a single male holotype as Banta (1970) believed. USNM 234, which is extant but in poor condition, bears resemblance to the specimen in Figs. 1–4 in Girard's atlas, and may be the female syntype. UMMZ 3849 was originally USNM 207, not USNM 233 as Banta (1970) had argued. A comparison of UMMZ 3849 with Fig. 5 in Plate 21 of Girard's (1858b) atlas reveals that the former was not used to illustrate the male postcloacal region, and hence it is not the male syntype. Also, USNM 233, which is missing and presumed lost or destroyed, was not likely the male syntype. However, information from the original ledger indicates that USNM 233 was the only short-horned lizard specimen from the Salt Lake area associated with Captain Stansbury, and hence it undoubtedly was the specimen used for Figs. 6–10, captioned as "*Phrynosoma douglassii*" [sic] in Girard (1852).

Acknowledgments.—I thank T. Hartsell, J. Poindexter II, K. Tighe, and R. Wilson (USNM), R. Nussbaum and G. Schneider (UMMZ), A. Resetar (FMNH), T. Anton (CA), and N. Gilmore (ANSP) for providing digital scans of records, database files, photographs, or loaned specimens. J. Collins (Center for North American Herpetology) and the Interlibrary Loan Services of Clemson University kindly and expeditiously sent me literature. I. Stocks prepared the final version of the figures. I also wish to thank R. Espinoza, S. Gotte, J. McGuire, and an anonymous reviewer for helpful comments on the manuscript.

Morphometrics is defined as the numerical description of form (Lestrel 2000) and is a field that intersects a number of other biological disciplines ranging from the medical sciences (e.g., Gil et al. 2002) to genetics (e.g., Iriarte et al. 2003) to conservation biology (e.g., Clarke 1995). Because of the wide-ranging applications of morphometrics, the representation and assessment of measurement error (ME) is crucial (Yezerinac et al. 1992). Generally, ME is of greatest concern when trying to measure very small features or trying to detect very small differences among traits or individuals, such as fluctuating asymmetry.

Fluctuating asymmetry (FA) is a measure of developmental stability, the ability of organisms to buffer stresses during development. FA examines the frequencies within a population of normally distributed minor deviations from perfect bilateral symmetry (Hoffman and Woods 2001; Møller and Swaddle 1997; Palmer 1994). ME is of particular concern in FA analyses, because high ME causes an increase in variance without altering the mean (Palmer and Strobeck 1986). Thus, high ME inflates FA and masks differences in FA among populations by increasing variance (Björklund and Merilä 1997; Palmer 1994; Van Dongen 1999). Additionally, the subtle nature of FA can cause ME to be on the same magnitude or greater than that of FA (Palmer and Strobeck 1986), making it very important to accurately account for all possible types of ME.

One method to minimize ME in FA and other morphometric studies has been to use image analysis, where photographs are taken of each individual and software is used to make the actual measurements (Iriarte et al. 2003; Kokko et al. 1996; LeClerc et al. 2005). While some researchers find this to be an undesirable method (Hayek et al. 2001), image analysis is an important tool for measuring animals that are small or difficult to handle, situations where ME may frequently be larger than FA. While Palmer (1994) warns of pixellation error, the increased availability of digital cameras taking high-resolution pictures has reduced this problem. Nonetheless, few attempts have been made to establish a protocol for image analysis of FA.

One strategy for assessing ME in image analysis is to take one photograph per individual and measure each photograph three times (e.g., Gallant and Teather 2001; Trotta et al. 2005). This assumes that the ME only consists of error from the image analysis. In capturing a digital image, a three-dimensional animal is transformed into two dimensions. Slightly different three-dimensional positions may alter the two dimensional representation, causing the length of a trait on the photograph to inaccurately represent the three-dimensional trait. Thus, it is possible that error is obtained during positioning (McCoy and Harris 2003), as well as during image analysis. In this study, we compared ME from measuring one photograph three times (image analysis ME) to ME from measuring three pictures, and thus three positions, once each (overall ME or the combination of positioning error and image analysis ME).

Materials and methods.—Thirty-one Spring Peeper (*Pseudacris crucifer*) tadpoles and 31 metamorph Fowler's Toads (*Bufo fowleri*) were collected from Hancock Biological Station in Calloway County, Kentucky, USA in Spring 2005. Individuals were photographed using a Pixera model PVC 100C digital camera through a Wild microscope at 40x magnification. All individuals were photographed while alive and were returned unharmed to the site of their collection. Tadpoles were conscious during image capture but tended to remain still after positioning. Metamorph toads lacked this tendency and were anesthetized using a dab of a 2.5% lidocaine solution on the head. Photographs were taken in replicates of three and each individual was repositioned for each photograph. Positioning was limited to a few minutes for each photograph to minimize stress on the animals. Each replicate consisted of one photograph for the tadpoles and two photographs per replicate for the toads: one of the body and one of the legs. All photographs were taken with 1280 x 1024 pixels.

Photographs were measured in pixels using the software ImageJ (NIH 2006). The right and left sides were measured for all traits. Two traits were measured on tadpoles: eye width and the distance from the eye to the nare. Eight traits were measured on toad metamorphs: eye width, the distance from eye to nare, humeral length, radio-ulnal length, the distance from the humerus to the femur, femoral length, tibio-fibulal length, and calcaneum length. For each individual, the first photograph taken was measured three times, and the second and third photographs were measured once each. One data set was created from the first photograph measured three times for determining image analysis ME. The second data set was created from the first measurement of the first photograph and the measurements from the second and third photograph determining overall ME. A two-way mixed model ANOVA was performed on each data set for each trait using individual as a random effect and side (left or right) as a fixed effect, a standard method for determining whether ME is lower than FA (Palmer 1994). The significance of this interaction indicated that the between sides variation among individuals was greater than the ME and, thus, could be reliably analyzed for FA assuming it met all other assumptions (Merilä and Björklund 1995; Palmer and Strobeck 1986). This analysis was used as qualitative assessment of ME, mimicking the procedures used in routine FA analyses. In order to maintain appropriate alpha values, Bonferroni corrections were used (Hochberg 1988).

To directly compare image analysis ME and overall ME, the coefficient of variation was used as an estimate of ME. Because the true value of the trait length is not known, accuracy cannot be assessed. The coefficient of variation thus provides a measure of precision. The coefficient of variation was calculated for each side (right or left) of every trait for each individual for the image analysis ME data set and the overall ME data set. MANOVAs with all traits were used to determine whether image analysis ME and overall ME were significantly different for each of the tadpole and metamorph toad data (Bernal and Clavijo 2009) using Pillai's trace statistic (Zar 1999). Univariate ANOVAs with Bonferonni corrections were performed to determine which traits showed significant differences (Tabachnick and Fidell 2007). Statistics were performed using PC SAS (SAS 2004).

Results.—For the qualitative assessment of ME, all tests for image analysis ME were highly significant, indicating that ME was lower than FA (all $F30,_{124} \geq 2.426$, all $P < 0.001$; Table 1). Eye width in tadpoles and eye width, the distance from eye to nare, humeral length, tibio–fibulal length, and calcaneum length in metamorph toads had low overall ME compared to FA (all $F30,_{124} \geq 1.869$, all $P < 0.01$; Table 1), while the distance from eye to nare in tadpoles and radio-ulnal length, distance from humerus to femur, and femoral length in metamorph toad had overall ME greater or of the same magnitude as FA (all $F30,_{124} \leq 1.52$, all $P \geq 0.06$; Table 1).

For the direct comparison of image analysis ME and overall ME, the average coefficient of variation for overall ME was always greater than the image analysis ME (Fig. 1 and 2), although this difference was very small for some traits. In tadpoles, there was no significant difference between image analysis ME and overall ME ($F4,_{57} = 1.30$, $P = 0.28$; Fig. 1). In metamorph toads, image analysis ME and overall ME were significantly different overall ($F16,_{45} = 8.18$, $P < 0.0001$), and these differences varied by trait (Fig. 2).

Discussion—Image analysis ME was consistently lower than overall measurement error, although the magnitude of this difference varied by trait. This shows high accuracy in the use of software to measure traits. The F-statistics were higher for overall ME than for image analysis in all traits, indicating some positioning error in all traits. The difference was large in some traits, resulting in high overall ME, which indicates that positioning error is a problem in those traits.

Some traits may be more prone to high positioning error than others. Most of the traits that consistently had elevated positioning error occurred on the limbs or were associated with them: humeral length, distance from humerus to femur, femoral length, tibio–fibulal length, and calcaneum. In animals with

TABLE 1. Results of the interactions from the two-way, mixed-model ANOVAs to assess measurement error. All F-tests had 30 and 124 degrees of freedom. P-values are Bonferroni corrected.

	Image Analysis ME			Overall ME		
	MS	F	p-value	MS	F	p-value
Tadpoles						
Eye Width	10.57	2.43	< 0.001	9.95	1.87	0.02
Eye to Nare	167.21	2.91	< 0.001	78.49	1.12	0.56
Toads						
Eye Width	257.25	4.11	< 0.001	220.64	3.47	<0.001
Eye to Nare	100.13	5.66	< 0.001	125.39	3.27	<0.001
Humerus	849.58	10.65	< 0.001	619.38	4.69	<0.001
Radio-ulna	441.30	4.52	< 0.001	254.78	1.52	0.12
Humerus to Femur	906.34	18.45	< 0.001	984.11	1.36	0.23
Femur	1774.44	22.89	< 0.001	1356.81	1.25	0.39
Tibio-fibula	412.40	17.88	< 0.001	378.11	2.63	<0.001
Calcaneum	169.63	14.20	< 0.001	182.27	3.23	<0.001

appendages, it is generally the limbs that are adjusted the most during positioning, and thus traits associated with the limbs would have a high potential for positioning error. Similarly, any other traits that are adjusted to a great extent during positioning, such as gills, cerci, or flexible mouth appendages, are likely to have higher positioning error than traits fixed on the body.

The occurrence of high positioning error in this study may also be related to the amount of time spent positioning each individual. Only a few minutes were spent during each positioning event. It may be possible to spend extended periods of time positioning each individual in order lower positioning error. However, this may only be possible in dead or preserved specimens (McCoy and Harris 2003; Vershinin et al. 2007), and, if FA is to be useful for studies of declining and endangered species or for monitoring programs, it would be inappropriate to sacrifice large samples of individuals (McCoy and Harris 2003). In these cases, it is important to minimize positioning time and overall ME simultaneously.

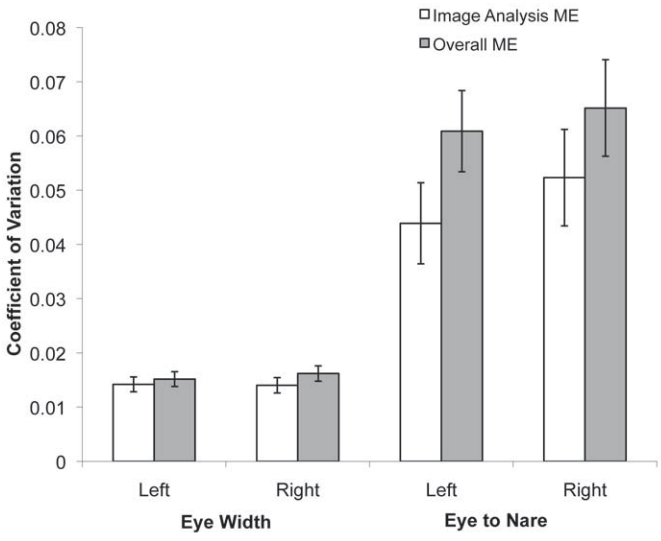

FIG. 1. Coefficient of variation for tadpole traits estimated from one photograph measured three times (image analysis ME) and three photographs measured once each (overall ME). Error bars represent standard error.

The occurrence of traits with low image analysis ME but high overall ME supports the hypothesis that determining ME using only one photograph, and thus only one positioning event, can lower the detected ME without lowering the actual ME. This could potentially lead to the assumption that ME is low enough to perform FA analyses, when it is not. High levels of ME may bias FA through inflation of the differences between sides (Palmer 1994; Van Dongen 1999), and thus, it is important to accurately detect the presence of ME in all forms, whether from image analysis or positioning error.

We recommend that, in all FA analyses utilizing photographs, two or more pictures be taken in which the individual is repositioned each time, reducing the chance that ME is artificially reduced and increasing the efficacy of FA analyses. Taking additional photographs has time costs and could cause additional stress on animals photographed while conscious. However, due to the possibility of failing to accurately detect ME, using only one photograph could jeopardize the integrity of FA analyses. In analyses with large sample sizes, it may be suitable to test a sub-sample of at least 30 individuals for overall ME with multiple photographs, just as Palmer (1994) recommends for the assessment of ME when samples are large or when replicate measurements are difficult to obtain. This sub-sample may be useful to assess both overall ME and image analysis ME to determine where improvements could be made in minimizing ME and which traits have consistently low positioning error.

Additionally, some studies have shown ME to vary among treatments (McCoy and Harris 2003), observers (Yezerinac et al. 1992), and measurement sessions (David et al. 1999). These factors should be investigated for image analysis ME and positioning error to better understand overall ME and to increase accuracy in FA analyses. Similar factors are also important in other types of morphometric studies. Further research on positioning error is also recommended for other areas of morphometrics that

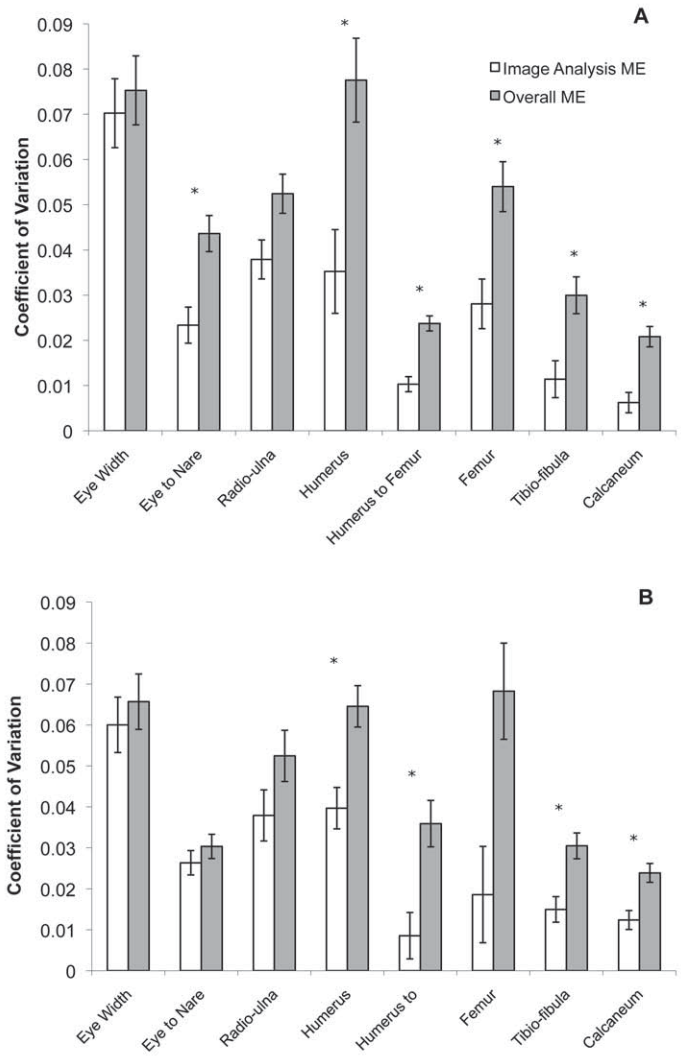

FIG. 2. Coefficient of variation for metamorph toad traits estimated from one photograph measured three times (image analysis ME) and three photographs measured once each (overall ME) for the left (A) and right (B) sides. Asterisks indicate significant differences at a Bonferroni corrected alpha. Error bars represent standard error.

currently utilize image analysis.

Acknowledgments.—We thank the Watershed Studies Institute, the Department of the Interior, U.S. Geological Survey and the University of Kentucky Research Foundation (06HQGR0087) via the Kentucky Water Resources Research Institute, the Dr. Morgan Emory Sisk, Jr. Memorial Scholarship from MSU, a Kentucky EPA EPSCoR grant, the Murray State University Center for Institutional Studies and Research (CISR), and the National Science Foundation (DEB-0109436 to HW and DMS-0531865 to R. Fister) for funding. We also thank E. Zimmerer, C. Fuller, C. Mecklin, and G. Kipphut for advice and manuscript revision. The handling of animals was in accordance with the policies of Murray State University's Animal Welfare Committee.

Electronic tracking devices (VHF, satellite, GPS, etc.) are the most direct and accurate method of quantifying individual movement patterns in crocodilians (Franklin et al. 2009). The manner of attachment includes: neck collars (Joanen and McNease 1970; Taylor 1984), back harnesses (Kushlan and Mazzotti 1989), surgical implantation (Franklin et al. 2009; Hocutt et al. 1992; Magnusson and Lima 1991), ingestion (Magnusson and Lima 1991), and direct attachment to either the head, neck or tail using pins, wires or nylon line, usually inserted through holes drilled in the keeled scutes or osteoderms (Brien et al. 2008; Franklin et al. 2009; Kay 2004; Martin and da Silva 1998; Muñoz and Thorbjarnarson 2000; Read et al. 2007; Seebacher et al. 2005; Strauss et al. 2008; Webb and Messel 1978a). However, protocols for attachment often lack important details (Strauss et al. 2008), and due to difficulties with recapture, it is usually assumed rather than demonstrated that animal and tissue health at the attachment site has not been unduly compromised.

In crocodilian species and/or size classes where the nuchal rosette comprises robust, strongly keeled osteoderms (e.g., *Crocodylus porosus* > 2.5 m total length [TL]), the rosette provides a convenient point of attachment on the mid-dorsal surface of the neck, which appears to give good signal attenuation (Franklin et al. 2009; Kay 2004). Transmitters can be bedded between the keels and attached with wires laced through holes drilled through the bony keels, but this method is dependent upon the presence of well-developed keels (Franklin et al. 2009; Kay 2004). The method described here was used with large *C. porosus*, and allows transmitters to be mounted on the mid-dorsal neck and secured with wire running under the length of the nuchal rosette, without collars and without needing strong keels for attachment. It should thus be suitable for all species and size classes of crocodilians with or without strong keels. The method involves four stages: (a) positioning subcutaneous stainless steel wires under the rosette; (b) making a transmitter mounting platform that is a mold of the central length of the rosette; (c) locking the transmitter to the platform with the wires; and (d) using additional molding material to extend and shape the platform so that it forms a complete mold of the rosette on the ventral side, and a dome on the dorsal side that encases and protects the transmitter. Based on recaptures, the attachment method is considered benign with regard to animal health.

Materials and methods.—Thirty satellite transmitters were attached to 29 Saltwater Crocodiles, *Crocodylus porosus* (total lengths [TL] 250–452 cm) captured in the Northern Territory of Australia (Kakadu National Park [N = 20], Mary River [N = 6], Blyth River [N = 2], Adelaide River [N = 1]) between September 2005 and September 2008 (Table 1), and their movements monitored weekly for the duration of transmission life. Four individuals were recaptured between 383 and 1049 days after the transmitter was first attached.

Adult male *C. porosus* (> 3.1 m TL, Webb et al. 1978) were the target group (N = 26, mean = 381 ± 7.1 cm TL), but one smaller male (250 cm TL) and two females (301 cm and 313 cm TL) with reduced keel size were included. Crocodiles were mostly caught by harpoon at night (N = 15) or with baited cage traps (N = 14) (Walsh 1987; Webb and Messel 1977), and one individual (61687, 312 cm TL) was caught in a drying pond. Crocodiles were caught in or adjacent to tidal saline (N = 20, saline) and non-tidal freshwater wetlands (N = 10), and were released at the site of capture (N = 19, 63.3%) or relocated (N = 11, 36.7%) as part of a relocation experiment (Table 1). All were individually numbered by scute clipping (Richardson et al. 2002).

Three types of satellite transmitter were trialed in this study (Sirtrack: Lower Hut, New Zealand), with general specifications from Read et al. (2007). The following transmitters were used: the KiwiSat 101 platform terminal transmitter (PTT; both satellite and VHF capability, 12 cm x 3.2 cm x 2.4 cm high, 300 g, N = 10); KiwiSat 101 PTT (satellite only, 9.3 cm x 4.3 cm x 3.4 cm high, 170 g, N = 16); and the smaller KiwiSat 202 PTT (satellite only, 8.5 cm x 3.2 cm x 2.0 cm high, 100 g, N = 4). All transmitters had 1 or 2 flexible aerials (approx. 20 cm long), stainless steel attachment loops (5 mm diameter, 2–3 on each side) on the transmitter base, and a salt switch which disabled transmissions when the transmitter was under water in saline areas (Fig 1). Five transmitters had an additional haul-out switch designed to turn the transmitter off if a crocodile was either in fresh water or on land for more than a few hours (Table 1).

After capture, each crocodile was immobilized with an intramuscular injection of pancuronium bromide (Astra Zeneca: North Ryde, New South Wales, dosage rates described in Bates 2001). The nuchal rosette area was disinfected with Betadine and injected with a local anaesthetic, Xylocaine (Astra Zeneca: North Ryde, New South Wales). Two stainless steel needles (230 mm by 3 mm diameter) were forced through the skin on the posterior side of the rosette, and with the aid of pliers, run subcutaneously under the osteoderms of the rosette to the anterior side. The two needles were then drawn through carrying two strands of stainless steel wire (breaking strain 41–68 kg) that had been soaked in 100% ethanol. There were thus two sets of two stainless steel wires (each approx. 50 cm in length) protruding through the skin at the

TABLE 1. Attachment details and performance of 30 satellite transmitters attached to 29 *Crocodylus porosus* (27 male, 2 females*) captured in the Northern Territory of Australia, between September 2005 and September 2008. One crocodile (61688^) was recaptured after 1049 days and attached with a new transmitter (34011^). First five transmitters contained haul-out switches. Transmitters 34008, 34010 and 34011 were still active at the time of writing (13 May 2009).

FIG. 1. Four strands of stainless steel wire threaded subcutaneously under the nuchal rosette of a 4.21 m TL Estuarine Crocodile (*Crocodylus porosus*) used to anchor the transmitter in place. KiwiSat 202 Platform Terminal Transmitter (PTT) placed in the middle of the four nuchal scutes with attachment loops angled outward and antennae pointed towards tail. Photo by G. Lindner.

anterior and posterior ends of the rosette (Fig 1).

The mold was constructed in two parts. First, a bed of marine epoxy ("Selleys Knead-it Aqua" with limited exothermic reaction) the width of the transmitter was made along the top of the rosette. The transmitter was positioned on this bed with the aerial/s posterior. Each of the subcutaneous wires was then threaded back through the attachment loops on both sides of the transmitter, tightened and crimped with aluminum or lead sleeves that locked the anterior and posterior wires together. Additional epoxy was then used to complete the mold of the rosette, maximizing the surface area of contact between the rosette and the mold, with the upper surface shaped into a dome encasing the transmitter (Fig. 2). Two openings were left in the mold to ensure the two terminals of the salt switch were exposed. In most cases the mold was sprayed with black paint after the epoxy had hardened and prior to release of the crocodile.

The mass (in air) of the transmitter plus mold was: KiwiSat 101 PTT unit (satellite and VHF) 500–520 g; KiwiSat 101 PTT (satellite only) 350–370 g; and KiwiSat 202 PTT (satellite only) 220–250 g. Given the smallest crocodile in this study was 250 cm TL (approximately 52 kg, Webb and Messel 1978b) and the largest was 451 cm TL (approximately 355 kg, Webb and Messel 1978b), transmitter units were 0.1 to 0.7% of body mass, and thus well within recommended limits of 3–5% of body mass (Kenward 2001). The time required to fit a transmitter declined from 45 to 30 minutes with experience.

Results.—The overall mean transmission life was estimated at 463 ± 69 days (N = 30, range 0–1209 days, Table 1), with 67.8% (N = 18) lasting more than 308 days and 14.3% (N = 4) exceeding 1162 days. As the actual time a transmitter remains attached to a crocodile is difficult to determine due to difficulties in recapturing individuals, transmission life was used as a minimum index of attachment life, as a transmitter with an expired battery can remain attached. Transmission life did not differ significantly ($t = 1.09$, df = 28, $P > 0.284$) between relocated crocodiles (376.82 ± 247.02 days) and those released at the site of capture (512.26 ± 432.38 days). Three transmitters ceased transmitting within 16 days, one of which failed because it had a salt and haul-out switch that interacted technically to switch the transmitter off permanently in fresh water. The failure of the other two transmitters could have been due to the haul-out switch turning off the transmitter if the crocodiles entered fresh water and did not return to salt water, which would be required to re-activate the transmitter.

Of the remaining 27, a further three stopped transmitting between 49 and 76 days, one of which also had the salt switch and haul-out switch anomaly. It indicates a maximum failure rate of 20%, two of which were due to electronic failure. As a detached transmitter will not transmit under water, attachment failure could be responsible for the other four transmitters (13.3%), although it could equally be due to interference with transmissions when crocodiles moved into heavily vegetated swamps under a closed tree canopy.

One crocodile was recaptured after 1049 days with the transmitter missing (368 days of transmission). There was no sign of necrosis, subcutaneous wires, or any damage to the nuchal rosette. It appeared that the subcutaneous wires had pulled through when the transmitter and mold detached, which likely resulted due to failure of the crimped sleeves. The crocodile appeared healthy (large fat deposits in neck and base of tail), and fresh injuries noted when it was originally caught had healed. It was refitted with a new transmitter (34011) that was still transmitting after 224 days (13 April 2009).

Three *C. porosus* were recaptured with transmitters still attached after 383 days (60687, re-caught 11 November 2006), 424 days (60689, re-caught 12 November 2006), and 951 days (61683, re-caught 30 June 2008). When the transmitters were removed, there was no sign of infection, tissue necrosis or damage to the skin or tissues of the rosette. One of these individuals (61683, 951 days) had grown 60.5 cm TL between captures, with the nuchal plate growing out and around the site where the wires entered the skin. This crocodile was the smallest (250 cm TL) in the study and was released *in situ* with transmitter still attached. Of the remaining

FIG. 2. Satellite transmitter attached to the nuchal rosette of a 4.23-m TL Estuarine Crocodile (*Crocodylus porosus*). Stainless steel wires threaded beneath the nuchal rosette were used to anchor the transmitter in place and marine epoxy was moulded to the crocodile to secure the entire unit in place. Photo by G. Lindner.

two, the mold was undamaged in one (383 days), but broken away on the edges in the other (424 days). In the latter case salt had been mixed with the epoxy on the untested assumption that it would counter the haul out switch at the time of mounting; it may well have weakened the epoxy material. In none of the recovered transmitters were there any teeth marks or damage consistent with attacks on the neck region by conspecifics.

Discussion.—Our study reaffirms that the nuchal rosette is a good site for attaching transmitters to crocodilians, and that use of a mold held in place with subcutaneous wires is an effective method of attachment, with apparently limited adverse effects on the animals, that is well suited to long-term movement studies. In cases where young animals may be growing rapidly, and transmissions are only required for a short period of time, it would be possible to use some form of temporary erodible pin to release one end of the transmitter after a known time (Goodyear 1993) so that it can pull the wires through the skin. In terms of physical dimensions, the height of the mold on the neck is set by the height of the transmitter being attached, and thus it would appear that the lower the profile of the transmitters, the shorter the mold dome on the top of the neck. In our study, the height and robustness of the keels of individual crocodiles was largely irrelevant to the attachment process, making us confident that it can be used with crocodilian species that are not strongly keeled. Indeed, the whole concept of mounting an object on the rosette, using a mold with subcutaneous wires, was pioneered by the authors (GW, CM, DO) in conjunction with Cooper-Preston (1991), when she successfully mounted visual numbered tags on *C. johnstoni* (1.3–1.8 m long; N = 18), which have limited keeling. Recaptures < 2 years later had indicated no ill effects and several individuals were observed with numbered ID tags after 4 years (Cooper-Preston, pers. comm.). We are confident the method can be adapted for attaching electronic devices (VHF, GPS, satellite) to all crocodilians, given that the size of devices is appropriately scaled to animal size.

Acknowledgments.—We thank Tom Nichols, Robbie Risk, Adam Britton, John Pomeroy, Corey Bradshaw, Jonathan Nadji, Charles Whittaker, Buck Salau, Steve Winderlich, Kakadu traditional owners and other Kakadu personnel for field assistance and support. Use of Remote Laser Sensing Equipment to Measure Surface Temperature and to Predict Deep Body Temperatures of Small Lizards in the Field

Many lizards maintain their body temperature within narrow limits by adjusting to variations in their thermal environment (Adolph 1990; Angilletta 2001; Huey 1982). Critical body functions and behaviors, including active digestion, reproduction, and predator avoidance are closely coupled with the maintenance of suitable body temperature (Cowles and Bogert 1944). Thus, the ability to measure the deep body temperature of lizards is central to studying their physiology and behavior. When studying behavior, non-invasive methods are better than the traditional "noose and goose" technique. This is because they cause less disruption to the animal's natural behavioral patterns and less stress due to insertion of the thermometer bulb into the cloaca.

Hand-held laser guns or infrared thermometers (IRTs) are available to measure surface temperatures. They can be used to measure skin surface temperature of an animal, such as a lizard or frog, in order to estimate deep body temperature (Alberts and Grant 1997; Hare et al. 2007a, b; Rowley and Alford 2007). However, there are at least four difficulties likely to be encountered utilizing this device to indirectly monitor deep body temperature. 1) It may be difficult to approach an animal close enough to utilize the minimum-sized sensory field of the instrument without the animal fleeing (Hare et al. 2007a).With the device used by us the minimum-sized sensory field is a circle or ellipse with a minimum diameter of 21 mm with the device aimed from 0 to 250 mm from the object. 2) Even if close approach is possible, the minimum sensing field may still exceed the surface area of a small lizard to be monitored. This would result in inclusion of nearby objects in the field and composite temperature readings. 3) There may be insufficient clearance from objects such as leaves or blades of grass that may be blocking the path of the laser beam to measure temperature accurately. 4) The surface temperature of the animal may differ from deep-body temperature. Thus, some compensatory adjustment or correction would be required in order to estimate deep body temperature (Alberts and Grant 1997; Hare et al. 2007a, b; Rowley and Alford 2007).

In this study, we tested the feasibility of predicting the deep body temperature of a small (3–5 g), active, diurnal lizard in the field by measuring dorsal temperature with an IRT. To minimize the problem of habitat within the sensory field of the IRT contributing to the temperature reading, we captured the lizard with a noose and suspended it so that there was no background interference. To overcome the problem of the difference between surface and deep-body temperature, we constructed simple regression models relating these two temperature variables for four small lizard species in various habitats. Our study extends knowledge of the use of these devices from previous research (Alberts and Grant 1997; Hare et al. 2007a, b; Rowley and Alford 2007) by focusing on several different species of small elongate lepidosaurs while they are above ground and active in the field (Hare et al. 2007a, b). Also, we attempted to overcome the problem caused by confounding temperature of habitat in a unique way.

Materials and methods.—Data were collected during May and June, 2005. The four lizard species studied were *Uta stansburiana* (Monahans Sandhills State Park, Ward Co., Texas, USA), *Holbrookia maculata* (Rita Blanca National Grassland, Dallam Co., Texas, USA), *Anolis carolinensis* and *Sceloporus consobrinus* (Kisatchie National Forest, Natchitoches Parish, Louisiana, USA). Lizards were located and then watched for 3–5 min prior to approaching to take temperatures with the IRT. The 3–5 min delay ensured that a lizard had spent at least this much time in the thermal context where it was first seen. Temperatures of the dorsal surface of the lizard were measured on the ground before capture using a Raytek (PM-30, Santa Cruz, California) IRT. Capture usually was achieved using a noose of dental floss or fishing line affixed to the end of a fishing pole. Rarely, lizards were captured by hand. Lizards were handled for as short a time as possible, while data were collected, in order to minimize heat transfer between the surrounding air, the hand of the investigator, and the lizard. All post-capture temperatures of a lizard were obtained within 30 seconds of capture. Dorsal surface temperature was obtained within the first 10 seconds after capture using the IRT (see details below). Cloacal temperature, measured with a Miller and Weber (T-6000, New York) cloacal thermometer, was obtained within the ensuing 20 seconds. Mass was measured to the nearest 0.1 g using a Pesola scale. Snout–vent length and time from first sighting the lizard to its capture were also measured for each individual. If a lizard was chased for more than 5 minutes prior to capture, post-capture temperatures were not utilized in our analyses. After release of the lizard, the substrate temperature (Raytek) and air temperature 2–4 cm above the substrate (Miller-Weber) at the point of initial sighting were taken. All air temperatures were taken with the bulb shaded from exposure to the sun.

When taking the temperature with the IRT prior to capture, we attempted to approach the lizard close enough so that the device was less than 1 m from the dorsal surface of the lizard. This ensured the width of the sensory laser beam was $\leq$ 25 mm. In order to keep the shape of the sensory field of the laser beam as circular as possible, care was taken to keep the angle of the laser path as close as possible to perpendicular with the dorsal surface of the lizard. In reality the angle was between 45 and 90 degrees, so the field was usually ellipsoid in shape. We were unaware of the effect of orientation of the gun on effectiveness of the reading, i.e., whether the path of the laser is parallel or perpendicular to the axis of the lizard (parallel being more effective, Hare et al. 2007a), so we made no attempt to correct for this artifact with the pre-capture readings. A close-focus cone can be attached to the device so that the sensory field at very close ranges is 3–5 mm in diameter. However, with the cone attached the field widens

dramatically with distance so that readings of objects at one meter and greater distances are useless. To minimize time from pre- to post-capture reading, the close-focus cone of the device was not attached after the pre-capture reading. Therefore, the width of the sensory field was wider (a minimum of 21 mm) than the width of the animal (averaging 10–20 mm) when the device was triggered close to the animal (about four to 10 cm away). To minimize artifact from reflected temperature of reflective objects adjacent to the lizard the following method was employed. The noosed lizard was quickly suspended from the noose pole away from the ground or objects; its position was stabilized and tension of the noose around the neck was minimized by holding one hind foot of the lizard; a second investigator aimed the IRT so that its laser beam was perpendicular to the surface of the lizard, a few cm from the surface, and pointed away from any background interference (toward the sky). With the device triggered the sighting light was moved back and forth across and along the surface of the lizard for a few seconds and the maximum temperature reading was recorded. The reading of a lizard using this technique was tested for accuracy by taking subsequent readings of five *Holbrookia* with a constantan thermocouple laid snugly upon the lizard's dorsal surface with the wire end parallel to the lizard's surface. The thermocouple wires were attached to a Wescor 2-channel thermocouple thermometer (TH-65, Logan, Utah). Thermocouple readings were taken within the ensuing 10 seconds after the IRT reading and the initial contact of the thermocouple with the lizard.

Testing for the statistical significance of slopes and intercepts in regressions was performed using Type III mean squares (Milliken and Johnson 2002) in Analysis of Covariance (ANCOVA) as calculated in the PROC GLM procedure of the Statistical Analysis System (SAS; Cody and Smith 2006).

Results.—The strength of the relationship between dorsal surface temperatures and cloacal temperature was stronger when using the readings obtained when the lizard was suspended with the sky as the background (R^2 = 0.77–0.96) as opposed to when the lizard was sitting on the substrate (R^2 = 0.38–0.87) or when using only the adjacent substrate temperature (R^2 = 0.41–0.80; Table 1). The mean 95% confidence interval (CI) measured at the coolest temperatures recorded (Fig. 1) averaged ± 1.01°C (Table 2). The prediction interval (PI) averaged ± 2.09 (about twice the CI, Table 2).

The cloacal temperatures of each of the four species were higher than dorsal surface temperatures indicating a thermal gradient within the animals (Fig. 2). There was significant variation among the slopes and Y-intercepts of the regressions among the species and habitats (Tables 3 and 4). For the range of temperatures measured the regressions of the two species from the pine forest (*A. carolinensis* and *S. consobrinus*) had statistically similar and significantly smaller y-intercepts (indicating smaller differences between dorsal and cloacal temperatures) than those of the two species from more open desert-grassland or grassland habitats (*U. stansburiana* and *H. maculata*).

Two dorsal surface readings of five *Holbrookia* were taken in the field, first with the IRT using the sky as background, and then with a thermocouple reader. These readings were identical for two lizards, 2.0°C lower for the thermocouple reader for two individuals, and 2.8°C higher for the thermocouple reader for one individual. The average deviation was 0.5°C higher for the thermocouple reading, producing an absolute value difference between the two readings of 1.2°C. This suggests that readings using the two techniques and sensors are comparable.

All of the lizards studied were adults. Sizes of the lizards studied are shown in Table 5. There was marginally significant variation among species in SVL (Anova, P = 0.048, df = 3, 56) but there were no significant post-hoc differences between any two species (Tukey-Kramer post hoc tests, P > 0.05). There was a more significant variation among masses (Anova, P < 0.01, df = 3, 56) with that of *A. carolinensis* significantly lower than that of the other three species (Tukey-Kramer post hoc tests, P < 0.05). *Anolis carolinensis* is more slender than the other three species.

Discussion.—Regarding predictive accuracy, our results using the pre-capture surface temperature of a 3–5 g iguanine lizard on the ground as the predictor of cloacal temperature were similar to those of Hare et al. 2007a using post-capture readings with the similar-sized McCann's Skink (R^2 = 0.38–0.87, Table 1, mean = 0.56, for four species in this study; R^2 = 0.59 for McCann's Skink [Hare et al. 2007a]). In our study, capturing the lizard and

using the sky as background greatly improved accuracy over our pre-capture readings or Hare et al.'s post-capture readings (R^2 = 0.77–0.96, Table 1, mean = 0.87). One reason for our better post-capture accuracy could have been due to our attention to avoid reflective objects in the laser field by pointing the gun skyward. For small lizards that cannot be closely approached but can be easily captured, our post-capture technique may be useful for generating an accurate predictive model. With such a model the sample size to estimate the mean and variance of cloacal temperature of the population can be increased by measuring dorsal surface temperature alone.

Conversely, while our post-capture technique eliminates some of the confounding background noise in the measurement and provides more accurate predictive model of deep body temperature, at least two issues remain: 1) the relationship between dorsal and deep body temperature, and thus the most appropriate model, may vary significantly due to a number of factors whose influence is yet to be precisely described, 2) the advantage of remote sensing to eliminate the stress of capture for the lizard is not realized. On the other hand negating the need to invade the cloaca with a thermometer or thermocouple could not only relieve stress on the lizard but also may be beneficial in another way. Copulation sometimes is followed by rapid physiological and behavioral change in a female lizard such that she quickly becomes non-receptive to additional copulation (e.g., in panther chameleons, Ferguson et al. 2004, p.80). It remains to be investigated whether or not mechanical stimulation by insertion of an object into a female lizard's cloaca can artificially trigger such a response and interfere with future reproduction.

When plotted on a graph, the 95% prediction interval of a model for the deep body temperature of an individual subsequently sampled based on its dorsal body temperature is roughly twice the 95% confidence

TABLE 2. Prediction intervals (PI) and confidence intervals (CI) of the individual regressions of cloacal temperature versus dorsal body temperature of each species. Interval values were calculated at the data points closest to the regression origin (coolest temperatures recorded) for each species (see Fig. 1).

Species	95% prediction interval of regression	95% confidence interval of regression	PI/CI
Uta stansburiana	5.09	2.73	1.864
Sceloporus consobrinus	4.54	1.60	2.838
Anolis carolinensis	2.80	1.42	1.972
Holbrookia maculata	4.26	2.27	1.877
Mean	4.17	2.01	2.138

limit for the estimate of mean deep body temperature for the population for each species (Fig. 1, Table 2). This means that models constructed from measurements of both dorsal and cloacal temperature of a few individuals are best used to quickly increase sample size and arrive at a population estimate of cloacal temperature. This method eliminates the need to directly measure cloacal temperature of subsequent individuals.

For any model to be predictive there must be a stable relationship between the independent and the dependent variables. The ability of dorsal surface temperature to predict a higher core temperature with some precision suggests that a somewhat stable relationship between surface, and core was established using our procedure. In our study the cloacal temperature predicted from a given dorsal temperature for the two species from dry open desert or grassland habitats (*Uta* and *Holbrookia*) were similar using their respective models. However, predictions differed significantly for the species from a shadier and more humid pine forest (*Anolis* and *Sceloporus*), using each species' respective models (Table 4). Models constructed at a given location and season may have limited applicability and may be influenced more by current climate than species-specific morphology, behavior and physiology. Thus, two species with different body shapes (*A. carolinensis* with a slender body and *S. consobrinus* with a stocky body), but in a similar climate, had similar temperature models. Whether the relationship between dorsal surface and core temperatures of a population varies seasonally or daily with changing weather conditions needs to be explored in more detail. Also, the degree to which temperature differences between surface and core represent real pre-capture differences between surface and core temperature versus artifact due to more

TABLE 3. ANCOVA results testing for intercept and slope differences among the four lizard species *Uta stansburiana*, *Sceloporus consobrinus*, *Anolis carolinenesis*, and *Holbrookia maculata*. Species effect indicates significant variance among y-intercepts of the individual regressions; dorsal temperature effect indicates a significant overall slope; species by dorsal temperature interaction indicates significant variance among slopes of the individual regressions.

rapid cooling of the lizard's surface after capture requires further investigation.

When collecting data we purposely avoided the early-morning basking period and focused on the mid-morning to late-afternoon shuttling or maintenance phase of the day. Dzialowski and O'Conner (2001) clearly showed that heating and cooling profiles obtained during initial basking can differ from those obtained during temperature maintenance. The relationship between dorsal surface and core temperatures may be quite different and less stable during early morning basking or when the animals are not exposed to the sun.

Acknowledgments.—We thank Glenn Kroh and John Horner for help in preparing the manuscript. We thank the officials of Kisatchie National Forest, Monahans Sandhills State Park, Texas Parks and Wildlife, and Rita Blanca National Grassland for permission to conduct the study on protected lands. These include Dan Garcia, Bradley Kohls, Glenn Korth, David Riskind, and Nancy Walls. Research in Texas was conducted under provisions of Texas Parks and Wildlife Scientific collecting permit no. SPR-0609-146 to GWF. The study was conducted under the supervision of the TCU IACUC (protocol 3/20).Support for this research was provided by a grant from the Eppley Foundation. This research was in partial fulfillment of the requirements for a Master of Science degree for SEB.

"Quick" DNA Extraction from Claw Clippings of Fresh and Formalin-Fixed Box Turtle (*Terrapene ornata*) Specimens

Proven methods for obtaining quality DNA from turtles include clipping a small piece of the tail (Freedberg et al. 2005) or withdrawing blood from the femoral artery (Buchman et al. 2009). Although both of these methods are well established and produce high yields of quality DNA for molecular analyses, they are somewhat invasive and stressful to the animal. Another potential source for the high yield of quality DNA is the "quick" of the reptilian claw. The claw clipping of live specimens would serve as a less invasive method of tissue harvest thus limiting potential stress.

The reptilian claw is composed of a dorsal unguis plate and the ventral subunguis which encloses the quick, the soft viable tissue which serves as a source of DNA (Fig. 1). The quick is protected by the unguis and subunguis which are rich in beta-keratin contributing to the density and hardness of reptilian claws (reviewed by Toni et al. 2007). However, claw clippings must be long enough to provide a sample of quick within the claw for the beta-keratinized claw itself does not contain DNA.

Because of these dense and rigid beta-keratin structures of the unguis and subunguis surrounding the quick, we hypothesized that the quick of museum specimens might also provide usable DNA for molecular analyses. Common practices in the curation and long-term preservation of herpetological specimens routinely include the use of formalin ($H_2C(OH)_2$), an aqueous and saturated 37% (by mass) solution of formaldehyde or methanal (H_2CO) as a tissue fixative. A 10% formalin solution is used in standard curation practices to fix specimens by forming cross-links between adjacent protein chains and preventing autolysis and coagulation (Fink et al. 1979 in Simmons 1987). The fixation process of soft tissue in small specimens occurs in a few hours, whereas larger specimens are fixed and hardened by soaking overnight (Simmons 1987). Although the formalin molecule is small (ca. 48 g / mol MW) and has a relatively rapid diffusion rate for soft tissues, formalin diffusion though the rich beta-keratin claw would be slow thus protecting the quick tissue from complete formalin fixation during normal curation practices. We therefore questioned if the quick of formalin-fixed specimens may provide a usable source of DNA for molecular analyses.

In this study, we addressed two questions: 1) will the quick from fresh claw clippings provide high-quality DNA for molecular analyses; and 2) will the quick, potentially protected from formalin fixation by the surrounding hard and dense beta-keratinized tissue of the unguis and subunguis, allow for the extraction of usable DNA.

Materials and methods.—Fresh claw clippings from 49 *Terrapene ornata* were collected within the Matador Wildlife Management Area and 10 formalin-fixed specimens from the Texas Cooperative Wildlife Collection (TCWC) at Texas A&M University. Specimens sampled from the TCWC were collected from Brazos (N = 5; TCWC 13979, 18770, 20093, 20099, and 33110), Grimes (N = 2; TCWC 30692 and 30694), Leon (N = 1: TCWC 20096), and Walker (N = 2; TAM 297 and 298) counties, Texas. All claw clippings were stored in 22 ml (25 x 45 mm) Nalgene® vials containing ca. 10 ml of 95% ethanol prior to DNA extraction and claws from the MWMA were measured for maximum width and length.

Using a QIAGEN DNeasy Kit (QIAGEN, Valencia, California), we attempted to isolate genomic DNA from both fresh and formalin-fixed claws. An identical procedure (see QIAGEN DNeasy Kit) was used for formalin-fixed claws, except they were washed in 1X PBT three to five times one day prior to DNA extractions and then incubated in 1X PBT at room temperature overnight. This additional procedure is recommended for, but does not guarantee, the possible removal of formalin from preserved specimens allowing for DNA extraction (QIAGEN 2008).

After DNA extraction from all individuals, we attempted amplification of all DNA samples across four *T. ornata* microsatellite loci (111P, 12I, 2P, and 2T; Cureton II et al. 2009) using polymerase chain reaction (PCR). Each 20 µl reaction consisted of 4 µl 5X PCR Buffer (Promega, Sigma-Aldrich, Inc.), 0.6 mM of dNTPs, 2.5 mM of $MgCl_2$, 2.5 µM of bovine serum albumin (BSA), 0.025 µM of tagged primer, 0.05 µM of untagged primer, 0.05 μM of D4 Well-RED fluorescent primer, 0.5 U of DNA Taq Polymerase (Promega, Sigma-Aldrich, Inc.),

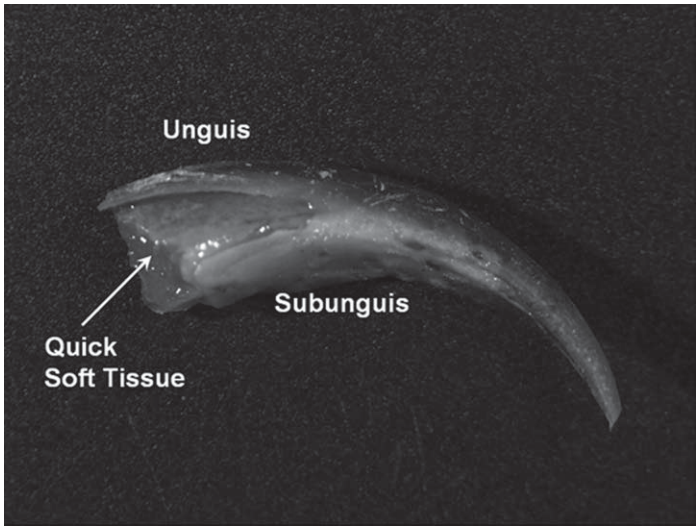

FIG. 1. Anatomical depiction of the quick potentially protected within a sheath-like structure of keratinized claw. A typical reptile claw is formed by a dorsal plate (unguis) and a ventral plate (subunguis). The unguis is curved both longitudinally and transversely and encloses the subunguis between its edges (Kent 1983; Weichert 1965). The softer subunguis and tissue that lies anterior to the terminal phalanx and between the unguis and subunguis provides viable tissue for DNA extraction. The unguis and subunguis are composed of beta-keratins and do not contain DNA.

2 µl of isolated DNA, and 6 µl of dH_2O. For all four loci, we followed the standard touchdown PCR protocol and annealing temperatures listed in Cureton II et al. (2009). To confirm the success of PCR, all products were run on a 2.0% agarose gel.

Based on the absence or presence of genomic DNA and a successful PCR, we classified each of the fresh 49 claw clippings into one of three categories: successful DNA extraction and PCR; successful DNA extraction but unsuccessful PCR; unsuccessful extraction. We used a model I, one-way analysis of variance (ANOVA) to investigate differences in maximum length and width (dependent variables) among these three classified result groups.

Results and discussion.—We successfully extracted and isolated genomic DNA from 36 of the 49 fresh field-collected *T. ornata* claw clippings (73.5% success rate) from the Matador Wildlife Management Area. The success of DNA extraction was highly dependent on the length and width of claw tissue which produced one of three results. Result group 1 (mean length = 3.809 mm ± 0.1860 SE, mean width = 1.463 mm ± 0.0524 SE, N = 36) had successful isolation of DNA, verified by PCR amplification of four *T. ornata* microsatellite loci (Cureton II et al. 2009). Result group 2 (mean length = 2.370 mm ± 0.420 SE, mean width = 1.180 mm ± 0.0800 SE, N = 2) had successful extraction of fragmented DNA, but it could not be amplified by PCR, and result group 3 (mean length = 2.719 ± 0.3170 SE, mean width = 1.176 ± 0.0949 SE, N = 11) resulted in no extraction of DNA. Differences among claw sample length and width in each result group were analyzed using a model-I, one-way analysis of variance of means. We found the mean length and width among claw samples within these three result groups to differ significantly ($F = 5.307$; df = 2, 46; $P = 0.008$ and $F = 4.042$; df = 2, 46; $P = 0.024$, respectively). Because claw tissue length significantly influenced the success of DNA extraction, we recommend that claw clippings be taken at lengths no less than 3.5 mm. Such lengths for adult turtles will most likely contain the viable tissue or quick of the claw. Claw clipping containing a quick sample is essential for DNA extraction because it is the quick, not the hard, beta-keratin claw, that contains DNA. Since developing this methodology, we have clipped an additional 23 claws with lengths of 3.5 mm (18 of which were from dead road specimens) and all claws yielded DNA that was amplified across 12 microsatellite loci (Cureton II et al. 2009).

Because beta-keratins, forming the hard and dense keratinized claw tissue, may protect the soft quick within the claw, we predicted similar success for the extraction of genomic DNA from the claws of formalin-fixed *Terrapene* specimens. Although we did not observe genomic DNA from the 10 formalin-fixed specimens on agarose gels, we successfully amplified the samples across four microsatellite loci with high success by doubling the overall primer concentration (in each reaction) listed in the materials and methods. Although amplifications from formalin-fixed claws did not produce as high of a yield for PCR product as did the fresh-claw clippings, all microsatellite alleles were able to be scored on a Beckman Coulter CEQ-8000. The descriptive statistics of these genotypes and alleles are reported elsewhere (Cureton II et al., unpubl.). Other extraction techniques for formalin preserved specimens (Chase et al. 1998; Shedlock et al. 1997) have also proven affective in yielding viable DNA for PCR amplification (Holiday 2003). However, to our knowledge this is the first paper describing successful results using claw clippings from formalin-fixed specimens.

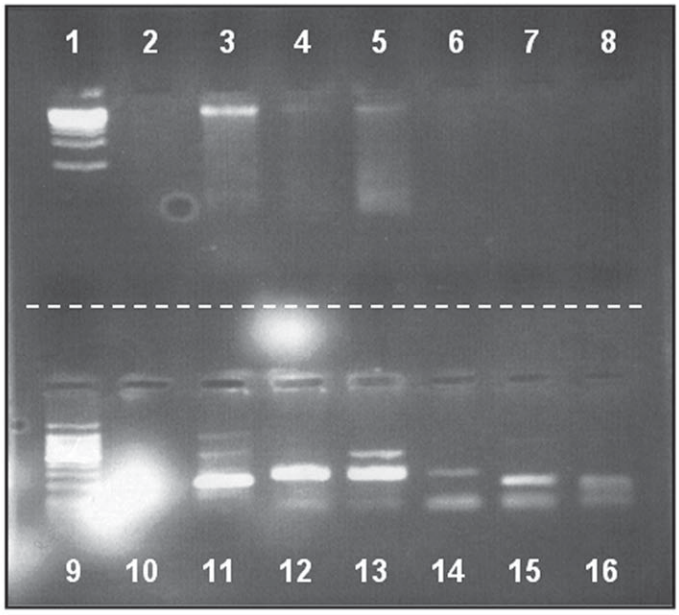

FIG. 2. Gel electrophoresis results showing genomic DNA (top row, lanes 3 through 8) and genomic DNA amplified by the microsatellite primer 111P (bottom row, lanes 11 through 16) on a 1% agarose gel where a standard 1000 BP molecular ladder appears on lanes 1 and 9; lanes 2 and 10 are empty. Lanes 1 and 11 = CG1; 3 and 12 = CG2; 5 and 13 = CG3 are fresh collected claw samples from dead road specimens. Lanes 6 and 14 = 00297; 7 and 15 = 00298; and 8 and 16 = 18770 are formalin-fixed specimens from the Texas Cooperative Wildlife Collection that were collected in the 1930s and 1940s.

Although we did not produce a high DNA yield from formalin-fixed specimens, we produced enough DNA for PCR amplification and it is likely that further pre-extraction washing would yield additional DNA. The ability to extract usable DNA from the quick of turtle claws that have been preserved and curated for more than 70 years (e.g., TCWC 297 was collected on 26 June 1936) will most likely prove to be useful to many molecular biologists working with museum-curated specimens of turtles and potentially other reptiles.

The utility of claw clipping as a less invasive technique than tail clipping (Freedberg et al. 2005) and femoral artery bleeding (Buchman et al. 2009) will aid in field collection of tissue samples. While all of these methods provide large amounts of high quality DNA, the former techniques may be more painful and cause increased stress for the animals being sampled. Thus claw clippings that produce similar DNA yields may offer some advantages over tail tip or blood collection. Claw samples only require storage in small vials of 95% ethanol and do not require heparinized collection tubes and ice as do blood samples. Finally, field collection of claw samples can be accomplished quickly (i.e., less than 30 sec) unlike blood collection from the femoral artery, and claw samples can be stored at room temperature requiring no additional preparation prior to methods of DNA extraction.

We have demonstrated the noninvasive utility of claw clippings as a viable source of high-quality DNA in both fresh and formalin-fixed *Terrapene* specimens. This described methodology and the

ability to extract usable DNA from claw clippings may prove extremely useful and aid in future molecular investigations of turtles and other reptiles.

Acknowledgments.—We thank D. C. Ruthven III and M. W. Janis of the Texas Parks and Wildlife Department who provided fresh claw clippings and L. A. Fitzgerald and T. Hibbitts, Curators of the Texas Cooperative Wildlife Collection, for allowing us to collect *Terrapene ornata* tissue samples used in our analyses. We are also grateful to L. A. Fitzgerald and M. L. Thies who provided valuable suggestions upon reviewing this manuscript and special thanks to M. L. Thies for discussion regarding the comparative anatomy of claw morphology. All turtles used in this study were collected under Texas Parks and Wildlife Scientific Research Permit No. SPR-0109-002 and all protocols were approved by Sam Houston State University's Institutional Animal Care and Use Committee Permit No. ID-08-09-09-1012-3-01 (granted to J. C. Cureton II).

Radiotelemetry has proven to be a valuable tool for determining amphibian activity, dispersal and migration patters because amphibians are often secretive, nocturnal and sometimes move long distances in short periods of time (Madison et al. 2010; Richards et al. 1994). Despite this success, transmitter attachment is often problematic for amphibians, especially anurans. Two techniques for transmitter attachment are available: "harness attachment" (also called belt or backpack) where radios are secured externally via a waist belt, and "implantation" where radios are inserted intracoelomically (sometimes subcutaneously) via surgery through the abdominal wall.

Harness attachment is most commonly used for anurans, because fitting harnesses *in situ* is relatively quick (5–10 min) and external transmitters with whip-like antennae are detectable over great distances (> 200 m), reducing the likelihood of losing subjects. If harnesses break or are fitted too loosely animals can shed transmitters; if fitted too tightly harnesses can restrict animal mobility and cause blood pooling in extremities (Bartelt and Peterson 2000). Skin lesions are often associated with external harnesses as well (Goldberg et al. 2002; Weick et al. 2005), which can cut through muscle if left unchecked. Skin lesions can also produce infections. A wide variety of harness materials have been used in past studies in an attempt to maximize transmitter retention while minimizing harm to animals (Goldberg et al. 2002), but injuries are still common. Given these possibilities and associated behavioral changes, external transmitters can produce conclusions on activity patterns that are not representative of the species as a whole (Bartelt and Peterson 2000; Johnson 2006).

To avoid these issues, many researchers favor internal transmitters. The acute stress associated with surgical implantation of radiotransmitters may be less taxing on animals than the chronic stress associated with harnesses, particularly for prolonged studies (Johnson 2006). Intracoelomic and subcutaneous surgical implantation techniques have been used on

a variety of amphibian taxa (Eggert 2002; Johnson 2006; Stouffer et al. 1983). Surgical incisions from transmitter implantation in both laboratory and field settings have healed well in previous studies (Goldberg et al. 2002; Johnson 2006; Weick et al. 2005). Disadvantages of internal transmitters include a smaller detection radius (20–50 m) of the helical coiled antennae, increasing the likelihood of losing subjects that move greater distances over short periods of times. There is also the potential for mortality either directly from surgical error or in response to anesthesia. For example, the most problematic aspect of implantation surgery on the Barking Frog (*Eleutherodactylus augusti*) was determining the appropriate level of anesthesia to use (Goldberg et al. 2002), which can vary with water temperature (ASIH et al. 1987). Infections are also possible.

Investigations into the relative impacts of radiotransmitter attachment techniques are necessary because of these variables. Generalizations might be made for species within the same genus or family, provided that the species in question share similar physiologies, habitat requirements, life-history traits and behavior. However, species-specific responses are known to exist (Rowley and Alford 2007) and rigorous assessments of data quality and methodology are scarce. Therefore, the objective of this study was to assess the suitability of waistband-harnessed and intracoelomic implantation radiotransmitter attachment techniques for use on Wood Frogs (*Lithobates sylvaticus*) and Boreal Toads (*Anaxyrus boreas boreas*). Adult Wood Frogs are relatively small (40–57 mm snout–vent length [SVL]) semi-aquatic anurans with thin, smooth skin. Boreal Toads are larger (63–78 mm SVL) terrestrial anurans with thick, rough skin.

Methods

Radiotelemetry was conducted from May through August in 2007 and 2008, on 111 Wood Frogs (62 external and 49 internal transmitters) and 38 Boreal Toads (22 external and 16 internal transmitters) in four wetland areas on the Canadian Boreal Plain near Whitecourt, Alberta. Animals were collected by hand, using a D-frame aquatic net, or in pitfall traps maintained by an amphibian monitoring study (the Study of Forestry and Amphibians [SOFA] project) established at the same sites. All animals (regardless of intended radiotransmitter attachment method) were transported to a base camp where body weight and SVL were recorded and radiotransmitters were attached. For Wood Frogs, 0.7 g BD-2 (external) and 0.8 g BD-2H (internal) transmitters (3 week runtime) were used. For Boreal Toads, 1.4 g BD-2 and 1.5 g BD-2H transmitters (9-week runtime) were used in 2007, and 1.6 g BD-2 and 1.7 g BD-2H transmitters (11-week runtime) were used in 2008. Transmitters were obtained from Holohil Systems Ltd. (Carp, Ontario).

Transmitter attachment and radiotelemetry procedures were approved by the Lakehead University Animal Care Committee. External transmitters were attached via waistband harnesses constructed from stretch bead cord following Baldwin et al. (2006). The surgical procedure employed for radiotransmitter implantation was similar to that described in Goldberg et al. (2002). Subjects were anaesthetized in 0.01% solution of MS-222. Time to suitable anesthesia was highly variable, but generally was 10–30 min. Boreal Toads took longer to anesthetize. Lateral incisions (12–15 mm) were made first though the skin and then through the muscle layer (rectus abdominus) along the right side near the ventral midline. Transmitters were inserted within the coelomic cavity along the muscle wall. Muscle and cutaneous layers were sutured separately using absorbable suture material (4/0 chromic gut in 2007 and 4/0 polydioxanone suture in 2008). Three to five simple, interrupted sutures were used to close each tissue layer. Tissue glue (Dermabond© in 2007; Vetbond© in 2008) was applied to sutures and surrounding skin to seal the cutaneous incision. Each surgical procedure took an average of 20–30 min. Animals were revived in local stream water and held overnight for observation before being released at the site of their capture the following morning.

Table 1. Summary of tracking periods.

Tracking Period (Days)	Boreal Toad (N)	Wood Frog (N)
1–9	4	10
10–19	9	57
20–29	3	22
30–39	6	9
40–49	8	7
*	5	3
70–89	3	

* 50–69 for Boreal Toads; 50–75 for Wood Frog

The 3-week runtime of the Wood Frog radiotransmitters required that transmitters approaching the end of their battery lives be exchanged for fresh ones. Individuals with external transmitters were refitted with new transmitters only if skin lesions were absent. Re-implantation of coelomic transmitters was performed in 2007 but not in 2008.

Animals were located once every 24–48 h by using R-1000 receivers (Communication Specialists Inc., Orange, California) with a 3-element yagi-style antennae. Each animal location was marked using GPS. Animals were examined for presence of injuries or infection associated directly with radiotransmitter attachment, or notable weight loss. Animals were recaptured for transmitter removal on the final day of the average runtime of their respective transmitters. Final weights of recaptured animal were recorded after radiotransmitters were removed.

Home range is likely to be positively related to observation period for species that do not actively defend territorial home ranges; the longer an animal is followed, the farther it moves. Both species in this study were expected to exhibit this relationship. Three simple movement parameters were derived to assess the suitability of both attachment techniques for collecting geospatial data. Home range area (HR, m^2) and linear distance travelled (LD, m) describe seasonal movement patterns. Mean patch spacing (MPS, m) describes movement behavior over a shorter timeframe (24–48 h).

Univariate analysis of variance was used to describe the relationships between transmitter attachment, tracking period (the length of time data were collected on an individual), animal condition (change in body weight and the presence of injuries), and movement parameters. Movement parameters were $\log_{10}$-

TABLE 2. Summary of animal fates (pooled 2007 and 2008): HR = home range, MPS = mean patch spacing, LD = linear distance, SE = standard error.

Species	Transmitter	Animals (N)	Injuries (N)	Deaths (N)	Lost (N)	Tracking Period (days) Mean (min–max)	HR Mean (min–max) ($m^{2)}$	MPS Mean ± SE (m)	LD Mean ± SE (m)
Wood Frog	External	62	24	*7	19	20 (1–74)	175 ± 13	15 ± 2	51 ± 5
	Internal	49	9	11	7	21 (3–55)	192 ± 17	16 ± 2	54 ± 6
Boreal Toad	External	22	9	*5	7	41 (6–79)	5839 ± 623	58 ± 9	302 ± 61
	Internal	16	0	5	9	28 (1–88)	3908 ± 675	73 ± 15	223 ± 41

The difference between the total number of animals and those that died or were lost represents animals that were successfully released.

* 1 confirmed case of predation.

transformed for analysis. Species were considered separately. Tracking period was divided into six categories for Wood Frogs, and seven categories for Boreal Toads (Table 1). Animals with single observations were omitted from analysis. A critical alpha value of 0.05 was employed.

RESULTS

Tracking period and movement.—Transmitter attachment method had no effect on Wood Frog tracking period or movement parameters ($P > 0.87$). Boreal Toad tracking period ($F_{1,36} = 4.08$, $P = 0.05$) and HR ($F_{1,36} = 4.25$, $P = 0.05$) were greater with external transmitters, but MPS and LD did not differ between transmitter types ($P > 0.47$) (Table 2). Tracking period interacted with Wood Frog HR ($F_{1,104} = 18.32$, $P << 0.01$) and LD ($F_{1,104} = 2.51$, $P = 0.03$), as well as Boreal Toad HR ($F_{1,36} = 7.12$, $P << 0.01$). All other movement parameters did not interact with tracking period ($P > 0.72$).

Mortality due to surgery.—Six animals did not recover from anesthesia (1 Wood Frog and 5 Boreal Toads, not included in the 149 animals used for our analyses). We do not know why these animals died; the general surgical methodology was consistent throughout, as was the concentration of MS-222 used.

Post-operatively, most sutures healed completely and suture material disappeared after three weeks. In 2008, there were four instances where Wood Frogs either developed lesions around sutures, or suture material did not fully dissolve by the time transmitters were removed. Nevertheless, these individuals were still active in the field. There were no confirmed cases of infection associated with surgical incisions or harness lesions. Multiple implantation surgeries had no observable impact on animals in 2007, with the exception of one Wood Frog that exhibited severe weight loss.

Weight loss.—Transmitter attachment method was associated with changes in body weight in Wood Frogs ($F_{1,43} = 6.43$, $P = 0.02$). More animals gained weight with internal transmitters than with external transmitters, although individuals from both categories exhibited weight loss (Table 3). All Boreal Toads observed until the end of their transmitter runtimes exhibited weight gain regardless of transmitter attachment method (Table 3).

Injuries.—Injuries were associated most commonly with external transmitters (Wood Frog: $F_{1,104} = 8.48$, $P < 0.01$; Boreal Toad: $F_{1,36} = 8.11$, $P < 0.01$) (Table 2). Injuries interacted with tracking period for Boreal Toads ($F_{1,36} = 13.51$, $P < 0.01$), but not Wood Frogs ($F_{1,104} = 3.14$, $P = 0.08$). The presence of injuries did not influence the movement parameters of either species (Wood Frog: $P > 0.39$; Boreal Toad: $P > 0.11$). Injuries were most common and developed earlier among Wood Frogs.

Susceptibility to predation.—There were only two confirmed cases of predation (Table 2), both associated with external transmitters and attributed to avian predators.

Reproduction.—The presence of external transmitters did not prevent amplexus. Grasping males would sometimes shed transmitters fitted to gravid females. Amplexus was not observed in animals fitted with internal transmitters, but there was no evidence suggesting implantation interfered with reproduction (but see Heemeyer et al. 2010).

DISCUSSION

Transmitter attachment method had mixed effects between Wood Frogs and Boreal Toads. Both transmitter types were able to capture Wood Frog movements to the same degree. However, Boreal Toad home ranges were larger with the use of external transmitters. The toads were capable of pulse movements that far

TABLE 3. Summary of animal weight change observed during 2008 for 43 Wood Frogs and 6 Boreal Toads.

Species	Transmitter Type	Weight Loss (N)	Weight Gain (N)	Proportion of Animals Exhibiting Weight Loss (%)	Tracking Period [Days] Mean (min–max)
Wood Frog	External	18	3	86	19 (7–40)
	Internal	12	10	55	18 (13–22)
Boreal Toad	External	0	3	0	54 (34–79)
	Internal	0	3	0	68 (53–87)

exceeded the detection radius of internal transmitters, and were easily lost during these periods. This also accounts for the shorter tracking periods reported for Boreal Toads fitted with internal transmitters. HR values for both species and Wood Frog LD expressed a positive relationship with tracking period, as expect for species without fixed, defended territorial home ranges. MPS was not affected by tracking period, which reflects the relative scales of the three movement parameters. Home range and LD reflect areas exploited and distance traveled over the entire tracking period, whereas MPS reflects the distance an animal can travel in a single tracking interval (24–48 h).

Internal transmitters appear to be most appropriate for longer studies, since the chance of developing lesions as the result of chronic harness exposure increases with time. More Wood Frogs gained weight when fitted with internal transmitters than those with external transmitters. Although amphibian weights are known to be extremely variable and are often linked to dehydration (Stebbins and Cohen 1995), the weight changes observed corroborate our data on abrasion injuries which demonstrates that transmitter implantation is in fact less harmful to anurans. While there are health risks associated with either radiotransmitter attachment technique (Goldberg et al. 2002; Weick et al. 2005), the chronic distress associated with belt abrasion appears to be greater than the short-term and admittedly intense strain imposed by radiotransmitter implantation.

Boreal Toads appear to be better than Wood Frogs at withstanding the perturbations associated with transmitters. In the case of harness attachments, this could be attributed to skin structure (thickness and irregularity) and body size, but might also reflect the relative transmitter-to-animal weight ratio. The transmitter percent of body weight in Wood Frogs (approaching 10%) was greater than that for Boreal Toads (under 5%). Our findings support the recently recommended maximum ratio of 5% (Goldberg et al. 2002).

Our data also support the notion of species-specific transmitter effects (Rowley and Alford 2007), although generalizations can be made. Internal transmitters are recommended for smaller-bodied anuran species with semi-aquatic life-history traits, like Wood Frogs and many other species belonging to the genera *Rana* and *Lithobates*. Larger species, and those sharing more terrestrial or semi-arid life-history traits (e.g., *Bufo* and *Anaxyrus*) are likely better able to withstand waistband harnesses. It is also necessary to consider a species' behavior. Internal transmitters were capable of capturing the movements of Wood Frogs as accurately as external transmitters. However, external transmitters were better able to capture the longer-distance pulse movements of Boreal Toads. We generally recommend internal transmitters whenever appropriate.

The Eastern Hellbender (*Cryptobranchus alleganiensis alleganiensis*) is a large, aquatic salamander historically found throughout the eastern United States (Mayasich et al. 2003). Hellbender populations have experienced drastic declines in recent decades throughout their geographic distribution (Wheeler et al. 2003), which has created a critical need for widespread data collection of biological samples (e.g., blood or tissue samples for genetic analysis) and accurate growth data. However, acquiring biological samples and accurate morphological measurements of large salamanders in the field can be difficult.

Restraining and measuring hellbenders using existing restraint devices is problematic due to their large size, muscular body and tail, and the production of copious amounts of mucus (Wise and Buchanan 1992). To safely collect biological samples and obtain accurate measurements, it is necessary to restrain individuals to minimize handling time, stress, and the potential for injury to the animal and researchers. Traditional measuring techniques usually involve either restraining animals by hand or placing them on a standard fish measuring board (Herke 1977). However, measuring boards do not contain restraints to prevent individuals from struggling during measuring or blood and tissue collection which can increase the amount of handling time for more active individuals. Methods that have been developed to restrain and measure amphibians in the field include an anuran restraining device (Bourque 2007), a "mander masher" (Wise and Buchanan 1992), a modified clear plastic tube (Mathis 1991), and a PVC "salamander stick" (Walston and Mullin 2005). The anuran restraining device is designed specifically for a frog's morphology and would not fit a large salamander, while the latter three devices do not provide adequate access to the salamander's tail and stomach for sample collection. Squeezebox techniques have been utilized for handling venomous snakes (Quinn and Jones 1974), but to our knowledge few techniques have been specifically developed for restraining large salamanders. A technique which safely restrains individuals while allowing for consistent measurements can improve the accuracy and precision of morphological measurements in salamanders.

To resolve this issue, we have created the "bender board." This device is a specialized squeezebox designed to prevent struggling by captured hellbenders and allow for quick, accurate measurements. The board is made from lightweight wood, wooden dowels, and polyfoam (Fig. 1). The box is assembled by nailing two 65 cm x 2 cm x 7 cm boards (A) to the long edge of a 65 cm x 2 cm x 29 cm baseboard (B). Next, two 32 cm x 2 cm x 7 cm boards (C) are nailed to the ends of the baseboard to create an open box. Four 1 cm holes are drilled 7.5 cm in and 1.5 cm down from each corner on the long edge of the box. Two additional holes are drilled 4.5 cm in and 1.5 cm down from two corners of a separate 64 cm x 2.5 cm x 5 cm board (D). The holes on the separate board should line up with the holes on the constructed box as this will form the sliding restrainer board. A firm, nonabrasive polyfoam is then glued to one inside edge of the box and one edge of the sliding board. The polyfoam should be cut to conform to directional placement of salamanders into the board to hold the tail in place. Small holes should be cut in the polyfoam to allow for insertion of the dowels in the following step. Finally, the restrainer board is connected to the box by 31.5 cm x 1 cm wooden dowels inserted through the holes across the

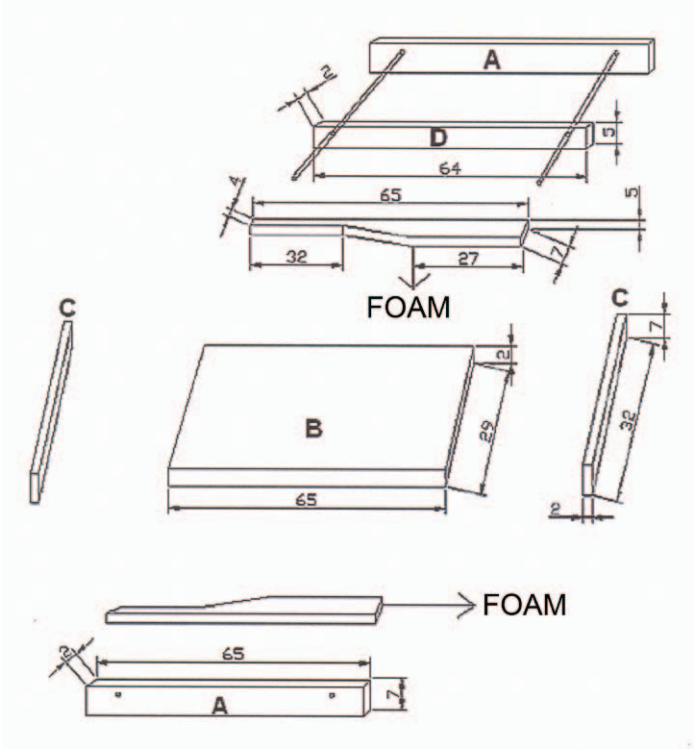

Fig. 1. Schematic of the components and construction of the bender board.

Fig. 2. Bender board shown holding an Eastern Hellbender.

board (Fig. 2). These dowels allow the animal to first be placed onto the board and then the restrainer board can be pressed against one side of the salamander. Large binder clips are placed behind the restrainer board on the dowels to hold it in place while in use. To use the bender board, the hellbender is placed onto the board with its head under the forward dowel, ventral or dorsal side up depending on the procedure and its legs are adhered laterally with tail and body straight by sliding the restrainer board closed and securing the binder clips. This allows for safe handling and measuring of total length and snout–vent length (SVL), drawing of blood, and marking individuals. This design is also ideal and efficient for use in the field when working alone. The approximate time to restrain hellbenders from the point of placement onto the board to securing the restraining board was under 10 seconds. Throughout the study 183 individuals ranging in size (SVL) from 26.2 cm to 38.3 cm were restrained using the board.

This design should increase the accuracy of measurements by eliminating the salamander's ability to struggle. The possibility of injury and stress are also reduced because researchers will not need to manually restrain individuals for longer than is necessary. The polyfoam padding creates a soft, non-abrasive cushion to securely restrain hellbenders without injury and it holds moisture which helps prevent desiccation and reduces the need to continually apply water during processing procedures. Although only tested on hellbenders, this design could easily be modified for use on other salamander species, particularly other large paedomorphic salamanders such as sirens (*Siren* spp.), amphiumas (*Amphiuma* spp.), and mudpuppies (*Necturus* spp.). Due to the polyfoam's ability to hold moisture, we recommend that researchers employ multiple boards as this would allow for adequate disinfection between sampling occasions and reduce the potential for disease transfer. This lightweight, relatively small "bender board" is portable, easy to use in the field, and can be modified to include carrying handles. Variations on the design could include replacing wooden materials with plastic to further decrease weight, improve durability, and increase the ease of cleaning. Although not illustrated, we recommend placing an additional nonabrasive restraint in the form of a small piece of plexiglass or similar material over the space between the anterior dowel to prevent individuals from sliding forward and under the dowel which could allow them to escape. The responsible use of this design could increase researcher sampling efficiency and measurement accuracy, while decreasing handling stress and the potential for injury. The use of the "bender board" also would reduce the need to anesthetize individuals using tricaine methane sulphonate (commercially available as MS-222) which has shown to produce adverse physiological effects and an alteration of behavior (Byram and Nickerson 2008; Fedewa and Lindell 2005).

Acknowledgments.—Animals were collected under permit #09-0162 issued to Nicholas G. Burgmeier by the Indiana Department of Natural Resources and protocol #08-025 issued by Purdue University Animal Care and Use Committee. Financial support for this project was provided by the Indiana Division of Fish and Wildlife, Wildlife Diversity Section state wildlife improvement grant (E2-07-WD0007) and Purdue University. We also thank the R. Williams' Lab and several anonymous reviewers for comments on previous versions of this manuscript.

There are a number of trapping methods available for capturing terrestrial snakes and numerous variations on these methods have been described (e.g., Fitch 1987; Rodda et al. 1999). Since the wooden box trap in association with drift fences was first described within the primary literature and refined with specific construction instructions (Burgdorf et al. 2005), the method has been widely applied (although often with some modifications) particularly within the southeastern United States (e.g., Hyslop 2009; Lee 2009; Linehan et al. 2010; Perry et al. 2009). It represents a useful method of capturing large terrestrial snakes (Burgdorf et al. 2005), a group that can be difficult to systematically sample. In the course of using these traps in Georgia, Florida, Tennessee, and Alabama, we have generated recommendations to make traps easier to maintain and which may decrease mortality of non-

target organisms. However, the effects of these modifications on trap efficacy for target snake species are not known.

In addition to snakes, numerous species, particularly mammals, are captured in box traps (i.e., non-targets). Rodents routinely captured in these box traps in the southeastern U.S. have included Cotton Rats, *Sigmodon hispidus*, and Old-field Mice, *Peromyscus polionotus*. Additional mammal captures have included, but are not limited to, Striped Skunk, *Mephitis mephitis*, Spotted Skunk, *Spilogale putorious*, Virginia Opossum, *Didelphis virginiana*, Pine Vole, *Microtus pinetorum*, Southeastern Pocket Gopher, *Geomys pinetus*, rabbits, *Sylvilagus* spp., Wood Rat, *Neotoma floridana*, and Long-tailed Weasel, *Mustela frenata* (Guyer et al. 2007; L. L. Smith, unpubl. data). At best, removal of non-target mammals from box traps is inconvenient and time consuming but can also be unpleasant and/or dangerous (e.g., skunks and weasels).

We suggest installing a side door in addition to the hinged door on top of the trap specified by Burgdorf et al. (2005). Figure 1d of Burgdorf et al. (2005) displayed 5.1 x 5.1 cm pieces of lumber within the corners of the box trap and another piece 15 cm from the corner. Within the original schematic these two pieces of lumber were separated with hardware cloth. We recommend replacing the hardware cloth within this gap with a hinged plywood door (Fig. 1). We recommend this door, which can be held shut with turn buttons, be placed at the opposite side of the trap as the door on the top of the box trap to facilitate easy flushing of mammals out the side. Venomous snakes can also be safely flushed out this door, or allowed to exit on their own. On occasions when regular tending of the trap may not be possible and exposure is a concern, the side door (as well as the top access door) can be left open to permit animals to escape the trap.

Burgdorf et al. (2005) suggested including a chick watering source inside the box trap. We suggest adding a shallow galvanized pan as a water source so that animals can submerge themselves; this may aid in thermoregulation. A small branch leaned against the side of the pan can be used as an access ramp by small vertebrates. A 30–60 cm piece of synthetic rope within the pan and anchored to the center or top of the trap also allows small mammals to escape the water (Borg et al. 2004). Ropes made of synthetic material are less likely to drain the watering pan due to capillary action.

FIG. 1. A hinged side door greatly enhances a researcher's ability to quickly and safely remove non-target captures from box traps.

We also reduced the size of box traps to facilitate ease of transportation to study sites. Although of limited concern when extended travel is not a component of installation, we found that reducing the length of the box from 48 to 42 inches (121.9 to 106.7 cm) and the height from 18 to 16 inches (45.7 to 40.64 cm) allowed for more traps to safely fit in the bed of a standard pickup truck.

Acknowledgments.—We thank P. Jones, B. Freeman, A. Reese, and A. Hawkins for constructing snake traps. Many individuals assisted by checking traps throughout the Southeast. We have complied with all applicable institutional animal care guidelines and obtained appropriate state permits for this research.

**Corresponding author; e-mail: irwinj@cwu.edu*

Batrachochytrium dendrobatidis (*Bd*) is an aquatic fungus that infects amphibians with the disease chytridiomycosis, a disease that has been implicated as one of the causes of worldwide amphibian decline (Berger et al. 1998; Bosch et al. 2001; Rachowicz et al. 2006; Skerratt et al. 2007; Stuart et al. 2004). Although the manner in which *Bd* is spread is not fully understood, the amphibian trade has been implicated as a possible source of dissemination (Fisher and Garner 2007; Parker et al. 2002; Picco and Collins 2008; Rowley et al. 2007; Schloegel et al. 2009). Amphibian trade results in transport of large numbers of individuals and species nationally and internationally; with >7,000,000 amphibians imported into the United States between 1998 and 2002 (Schlaepher et al. 2005), and >4,000,000 amphibians imported to Hong Kong, China, in a single year via air transport alone (Rowley et al. 2007). Many US imports are subsequently exported to European and Asian markets (Schlaepher et al. 2005). The United States is one of the few countries to track import and export, but no regulations require screening for pathogens such as *Bd*. In 2008, the World Organization of Animal Health (OIE) listed *Bd* as OIE-notifiable, and developed standards for amphibian trade (http://www.oie.int/eng/normes/fcode/en_sommaire.htm; accessed 5 April 2010).

Bd has been isolated from Northern Leopard Frogs, *Rana pipiens*, from two biological supply companies in Massachusetts and Minnesota, USA (Woodhams et al. 2008). This and other research has suggested that *Rana pipiens* shipped from biological-supply houses may be a carrier for *Bd* (Fischer and Garner 2007; Woodhams et al. 2008).

Charles D. Sullivan Inc. (CDS) is a major biological supply company based in Tennessee, USA, specializing in amphibians for educational and research purposes. Charles D. Sullivan Inc. ships its products, both nationally and internationally, to over 100 institutions (as claimed on their web site: http://www.researchamphibians.com; accessed 26 April 2010). There have been hundreds of primary research articles based on specimens provided by CDS. To determine if frogs shipped from CDS had *Bd* we tested shipments of *R. pipiens* that were ordered for research purposes.

Shipments of 14 and 25 adult *R. pipiens* were shipped overnight from CDS to Central Washington University, Ellensburg, Washington, USA, on 18 October 2006 and 12 July 2007, respectively. Both shipments were immediately unpacked and transferred into clean and unused plastic containers, with each individual housed separately. Frogs were held at 10 or 15°C and the container cleaned twice weekly. Powder-free latex gloves were worn while handling frogs, with a new pair used for each frog. To determine infection status small pieces of shed skin were collected opportunistically from the enclosures of each of the frogs within 30 days of arrival and examined using differential interference contrast microscopy for the presence of *Bd* zoosporangia and zoospores. Samples were examined for no more than 10 min. If no *Bd* structures were found within 10 min, the sample was considered negative for the pathogen.

Bd was found in the shed skin of all *R. pipiens* (N = 39) sampled. Upon arrival at the laboratory, several frogs exhibited skin redness on the ventral surface of the abdomen and thighs, a common symptom in infected individuals (Pessier et al. 1999). These signs resolved a few days after the frogs were transferred into their enclosures. However, many frogs displayed signs of *Bd* infection intermittently throughout the 66- or 109-day experiments (Table 1), including redness on the ventral surface, lethargy, and excessive skin sloughing. There was no consistent pattern in the appearance and disappearance of the signs of *Bd* infection throughout the experiments. Six (15%) *R. pipiens* died during the experiments (Table 1).

These results indicate amphibians shipped from CDS may be infected with *Bd*. Given that the frogs were shipped overnight and assessed for *Bd* shortly after arrival, we consider it unlikely that they were infected during transport. The high infection rate more likely reflects holding conditions before shipping or natural infection rates. The relatively low mortality rates and high rates of infection in our experiments are consistent with previous research (Padgett-Flohr 2008; Woodhams et al. 2008) and suggest that some populations of *R. pipiens* may not be susceptible to mortality from chytridiomycosis and/or some strains of *Bd* are

TABLE 1. Number of *Rana pipiens* received in Ellensburg, Washington, USA, from a laboratory supplier (Charles D. Sullivan Inc., Tennessee, USA) testing positive for *Batrachochytrium dendrobatidis*, the length of the laboratory experiments for which the frogs were used, average survival time of each cohort, and the number of mortalities during each experiment.

Date sampled	No. Frogs Received from Supplier	No. Infected Frogs	Length of Experiment (days)	Average Survival Time with Infection (days)	Mortalities During Experiment
13 October 2006	14	14	109	103	6
14 July 2007	25	25	66	66	0

less virulent.

More investigation is needed to determine the extent of *Bd* in the amphibian trade. However, these results shed light on one possible mode of dissemination for *Bd*, and add to the evidence that *R. pipiens* shipped from biological supply houses may act as carriers for the pathogen. We recognize the importance of the amphibian trade for research and education, but our data emphasize the need to handle amphibians, and amphibian wastes, aseptically regardless of their origin. Further, in accordance with the OIE, we suggest systematic screening of imported and exported amphibians given the potentially devastating effects of *Bd* on amphibian persistence around the world.

Acknowledgments.—This work was financially supported by the MJ Murdock charitable trust and the Central Washington University College of the Sciences and Office of Undergraduate Research. All appropriate institutional animal care and collection permits were obtained for this study.

**Corresponding author*

An estimated 43.2% of global amphibians have experienced some reduction in population size (Stuart et al. 2004), with losses in several locations explained by the emerging infectious disease chytridiomycosis caused by the amphibian chytrid fungus *Batrachochytrium dendrobatidis* (*Bd*) (Berger et al. 1998; Daszak et al. 1999; Longcore et al. 1999). In Argentina, *Bd* infection was first reported in 2002, in the Spotted Thin-toed Frog, *Leptodactylus ocellatus* (Herrera et al. 2005). Since then, there have been additional detections in *Atelognathus patagonicus*, *Elachistocleis bicolor*, *Leptodactylus gracilis*, *Telmatobius atacamensis*, and *Telmatobius pisanoi* (Arellano et al. 2009; Barrionuevo and Mangione 2006; Fox et al. 2006; Ghirardi et al. 2009) in several locations in the country. Here we report the first occurrence of *Bd* in Argentinean tadpoles of two native anuran species, *Hypsiboas cordobae* and *Odontophrynus occidentalis*, in Luján, San Luis province, Argentina.

On 12 October 2009, 10 live larvae of *Hypsiboas cordobae* and *Odontophrynus occidentalis* were collected at random from a stream during a field survey in the Strict Nature Reserve

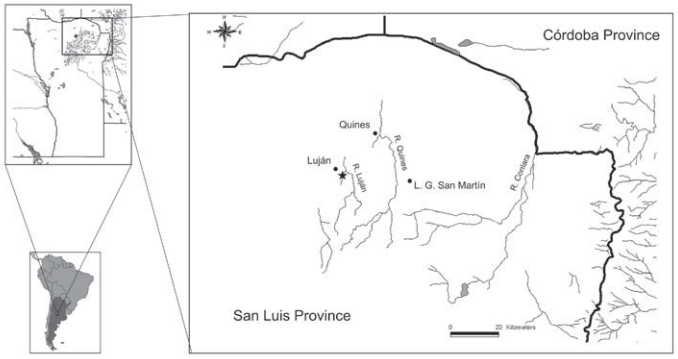

FIG. 1. Location (star) of *Batrachochytrium dendrobatidis* in San Luis province, Argentina.

"Quebarada de las Higueritas" (32.403ºS, 65.927ºW) at 800 m elevation (Anderson et al. 1970) (Fig. 1). The stream had a mean depth of 15 cm and flowed intermittently. This protected area is located in the northeastern part of the San Luis province and has climatic and geomorphological characteristics of the Chaco Serrano district of the Chacoan phytogeographic region (Cabrera 1976). Annual rainfall is 500–600 mm and is concentrated in late spring and summer. Vegetation is generally woody with less representation of drought-tolerant species that occur in neighboring regions. There are also abundant areas of grassland, frequently represented in elevated areas (Anderson et al. 1970). *Hypsiboas cordobae* is an endemic mountaine frog of Cordoba and San Luis, with a conservation status of Data Deficient (IUCN 2009). *Odontophrynus occidentalis* is broadly distributed in central and south-central Argentina, with an altitudinal range of 50–1500 m, and is categorized as Least Concern (IUCN 2009). Four other anuran species have been recorded at the site. During the field survey there was no evidence of anuran mortality and larvae seemed healthy.

The larvae were fixed in 10% neutral buffered formalin in the field and then transferred to 70% ethanol. All oral structures of tadpoles were examined visually in the laboratory under a stereoscopic microscope. Samples of the keratinized mouthparts were taken, dehydrated, paraffin-embedded and cut (Leica, RM 2125 RT) into 5 micron-thick sections for histological analysis. Then, tissues were stained with haematoxylin and eosin and examined with a light microscope (Olympus BX 40 Optical Co. Ltd., Tokyo, Japan). For *Bd* identification we followed the procedures described by Berger et al. (1999). Voucher specimens were deposited in the herpetological collection of the Universidad Nacional de San Luis, San Luis, Argentina (CH-UNSL 0420).

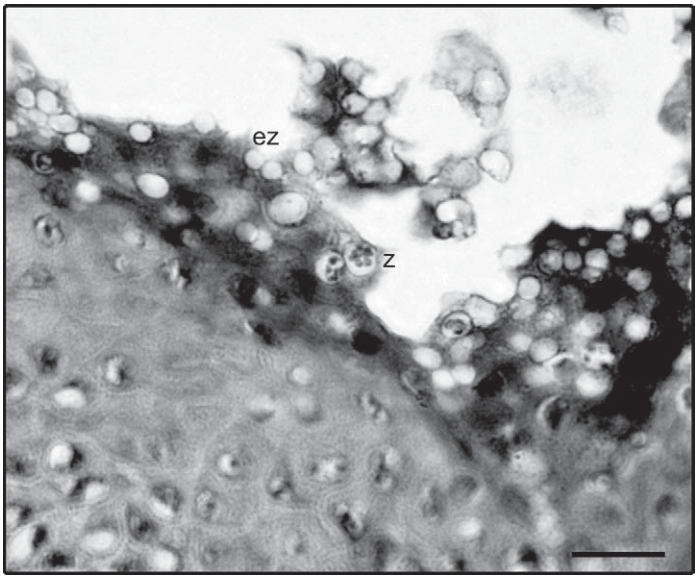

FIG. 3. Histological section of infected mouthparts of larval *Odontophrynus occidentalis* from San Luis province, Argentina, showing empty zoosporangia (ez) and containing zoospores (z). Scale bar: 30 µm. Photo by M. L. Arellano.

We identified anomalies in the keratinized mouthparts in five of 10 individuals analyzed. The anomalies included mainly lack of pigmentation in upper and lower jaw sheaths, erosion of their cutting edge and absence of serrations, and occasional loss of some labial teeth (Fig. 2). With regard to the histological analyses, seven of 10 larvae were positive for *Bd*. Spherical and ovoid zoosporangia, empty or containing zoospores, were identified in the keratinized mouthparts. The sporangia ranged between 5 and 12 µm in diameter (Fig. 3).

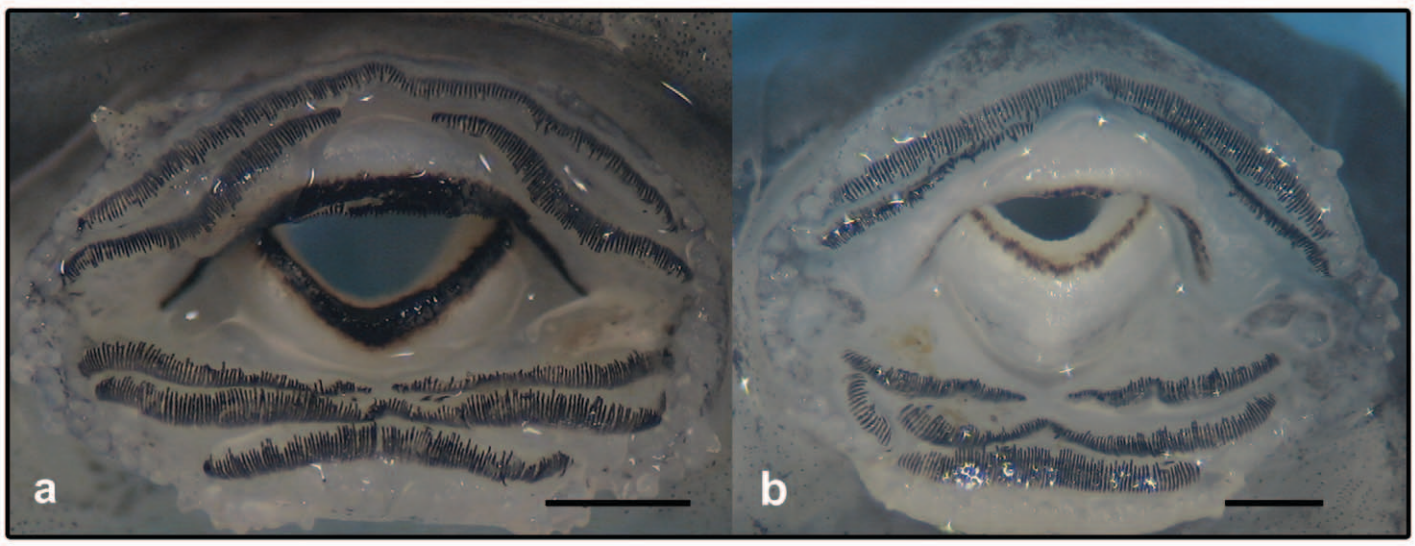

FIG. 2. Normal (a) and abnormal depigmented (b) keratinized mouthparts of larval *Hypsiboas cordobae* from San Luis province, Argentina. Scale bar: (a) 42 mm; (b) 46 mm. Photo by M. L. Arellano.

Our report of *Bd* infection extends the known distribution of the fungus to another region of the Chaco Serrano district (Cabrera et al. 1976), and to a new Argentinean province. This new locality is ca. 120 km from the locality of Ghirardi et al. (2009) in the province of Cordoba. Our discovery of *Bd* in San Luis province represents the first case of infection in tadpoles in Argentina and the presence of the fungus in two new native amphibian species. At present there are few data available on the susceptibility of Argentinean amphibians to *Bd*, and conservation efforts are needed to provide information on *Bd* distribution, ecological requirements, and pathogen-host interactions.

Acknowledgments.—This work was supported by PROICO 9401 UNSL and PIP 1422 UNLP. We are grateful to G. Romina Marti for collaboration in field sampling and to Mariano Lucia for providing the micrograph. We thank Pablo Grilli, Romina Ghirardi and Silvana Velazquez for their valuable assistance with the photographs.

Chytrid Infection of *Rana draytonii* in the Sierra Nevada, California, USA

PATRICIA TATARIAN
and
GREGORY TATARIAN
Wildlife Research Associates, 1119 Burbank Avenue
Santa Rosa, California 95407, USA
e-mail: trish@wildliferesearchassoc.com

Amphibian chytridiomycosis, caused by the chytridiomycete fungus *Batrachochytrium dendrobatidis* (*Bd*), has been correlated with the decline and extinction of many amphibian species worldwide (Lips et al. 2006). This emergence of this disease appears to be recent, based on samples taken from the California Academy of Science Herpetological Collection, located in San Francisco, California, USA, between 1897 and 2005. *Bd* infection was not detected in any of the 223 sampled amphibians from central California collected prior to 1961 (Padgett-Flohr and Hopkins 2009). Of the 687 individuals sampled overall, including Pacific Chorus Frog (*Pseudacris regilla*), American Bullfrog (*Lithobates catesbeianus*), Foothill Yellow-legged Frog (*Rana boylii*) and California Red-legged Frog (*R. draytonii*), 13.2% were infected with *Bd*, with the most frequent infection occurring in *Pseudacris regilla* (Padgett-Flohr and Hopkins 2009). Within the southern portion of the Sierra Nevada range in central California, populations of the Sierra Nevada Yellow-legged Frog (*R. sierrae* [formerly *muscosa*]) and Southern Mountain Yellow-legged Frog (*R. muscosa*) also have been found to support *Bd* (Fellers et al. 2001; Rachowicz et al. 2006).

Little research has addressed *Bd* presence or prevalence in *Rana draytonii* in the Sierra Nevada foothills, where eight independent populations of this federally listed Threatened species occur. To aid in this regard, we sampled for *Bd* within four of the eight known Sierra Nevada *R. draytonii* populations: Big Gun Diggings, Spivey Pond, Sailor Flat, and Hughes Pond (Fig. 1). We also update the occurrence of *Bd* at Hughes Pond, where *Bd* was first detected in 2007 (www. spatialepidemiology.net/Bd-maps/surveillance/s_country.asp; accessed March 2010). Information on disease occurrence is important to guide recovery efforts for *R. draytonii* and to manage existing populations.

Big Gun Diggings is located on the Michigan Bluff 7.5-minute topographic quadrangle, Placer County (98–1055 m elevation) and is designated as the PLACER 1 Critical Habitat (CH) Unit (USFWS 2008). The site is on a south-facing slope above the Middle Fork of the American River and includes six man-made ponds of various sizes up to 0.4 ha, which range in depth from being dry in the summer to >2.5 m deep.

Spivey Pond is located on the Sly Park 7.5-minute topographic quadrangle, El Dorado County (975 m elevation) and is identified as the ELDORADO 1 CH Unit (USFWS 2008). The site is on the North Fork Weber Creek, a tributary to the South Fork American River. Weber Creek flows from east to west through the pond, which is a 0.3-ha reservoir created by a weir on the western end of the creek.

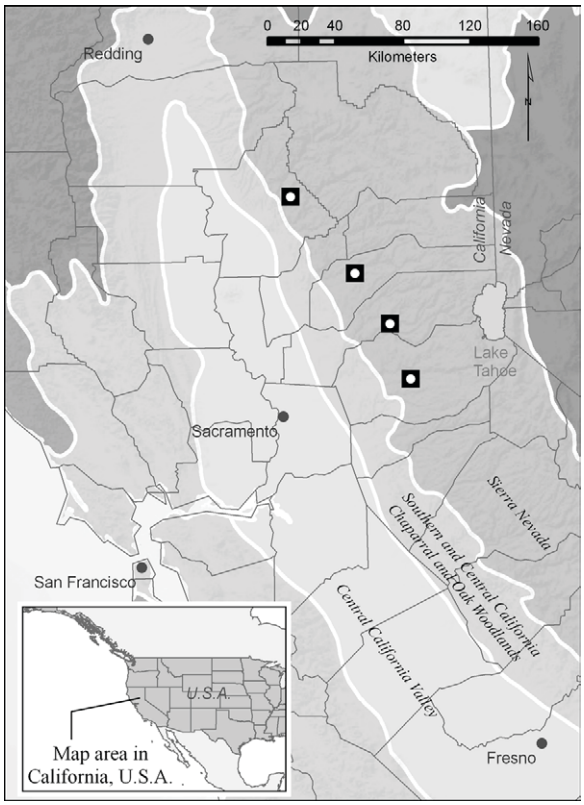

FIG. 1. Locations of study sites in the Sierra Nevada foothills, California, USA, where California Red-legged Frogs (*Rana draytonii*) were sampled for the amphibian chytrid fungus *Batrachochytrium dendrobatidis*.

Sailor Flat is located on the North Bloomfield 7.5-minute topographic quadrangle, Nevada County (929 m elevation), and is designated as CH NEVADA 1 (USFWS 2008). The site is on an east-facing slope above the South Yuba River. Several ponds occur in the area, although only one was sampled during this study, a perennial pond approximately 0.2-ha in size which ranged in depth between 0.3 and 0.69 m on the west and south, and more than 2 m on the north side of the pond.

Hughes Pond is located on the Berry Creek 7.5-minute topographic quadrangle and is designated as CH BUTTE 1 (USFWS 2008). Located at 760 m elevation in the Plumas National Forest, Butte County, the roughly 0.1-ha pond is situated northwest of the topographic blue-line headwaters of Jack Creek. Depths ranged between 0.3 and 1.4 m.

Surveys were conducted between 30 June and 12 August 2009, between 1800 and 2400. Weather conditions were clear and calm, with temperatures ranging between 15 and 32°C. Frogs were captured by hand, primarily using a dipnet which was sterilized between sites. Between-site contact between animals and containers used for animals was avoided, to reduce the potential for cross-infection. In addition, for comparison, we report *Bd* test results from 20 June 2007 and 19 May 2008 from Hughes Pond, using similar methods as described above. All individuals were identified using Biomark Passive Implant Transponder tags (Boise, Idaho, USA).

Frogs were swabbed for *Bd* using the methods described by Livo (2004). Fresh nitrile gloves were used when handling each individual. Swab samples were analyzed by Pisces Molecular, LLC (Boulder, Colorado, USA), which assayed the sampled DNA for the presence of *Bd* ribosomal RNA Intervening Transcribed sequence (ITS) region. Each polymerase chain reaction (PCR) run included three controls, a positive *Bd* DNA, a negative (non-batracho chytrid fungus) DNA, and a control with water. Signals ranged from no signal/below limit of detection (-) to very strong positive signal (+++).

Pseudacris regilla were observed at all sites, but only *R. draytonii* were sampled during this study. No frogs of any species were detected with outward signs of *Bd* infection, such as discoloration, sloughing of skin, anorexia or lack of self-righting reflex. No dead individuals were observed.

Three of the four ponds, Big Gun Diggings, Spivey Pond and Sailor Flat, were sampled only once. At Big Gun Diggings, *Bd* was detected on 5 of 8 animals (62%) sampled: 3 of 5 males and 2 of 3 females were infected, with infection rates ranging from no detection signal (-) to a strong positive signal (+++), as defined by Pisces Molecular, LLC. Tadpoles were observed but were not sampled for *Bd*. Only 2 adults were captured at the Spivey Pond site and *Bd* was detected on the adult female (+++), but not on the first-year frog. At Sailor Flat, 8 of 8 animals (100%) were *Bd*-positive, including 3 males, 3 females and 2 juveniles, with infection rates ranging from a strong positive signal (++) to a very strong positive signal (+++).

Multiple samplings at Hughes Pond detected *Bd* in 2007, 2008, and 2009. In June 2007, 4 of 13 (31%) animals sampled were *Bd*-positive: one juvenile returned a very strong positive signal (+++); another juvenile and an adult male had strong positive signals (++); another male returned a positive signal (+); while 4 females, 2 males and 3 juveniles were *Bd*-negative. In 2008, 2 of 7 (29%) animals had a very strong *Bd* presence (+++; 1 male and 1 juvenile): one of these had a strong (++) *Bd* signal in 2007 and one had not been infected in 2007. Two females and 3 juveniles were *Bd*-negative in 2008, of which one female and 3 juveniles were recaptures and were also *Bd*-negative in 2007. In 2009, *Bd* was detected on 5 of 7 (71%) individuals: 3 of 5 females and 2 of 2 males were infected, with signals ranging from no signal (-) to very strong positive signal (+++). In 2009, only one individual was recaptured from 2007 and showed an increase in infection from no signal or below detection (-) in 2007 to very strong positive signal (+++) in 2009. There were no other recaptures from 2007 and there were no recaptures from 2008.

Although the sample sizes in our study were extremely low, with only 2–8 animals sampled per site in 2009, *Bd* occurred at each site and the percentage of infection within sites (62% at Big Gun, 50% at Spivey Pond, 100% at Sailor Flat and 29–71% at Hughes Pond) appeared to be higher than previously reported rates for *R. draytonii* in central California. On average, 4% of *R. draytonii* were *Bd*-positive between the late 1800s and 2000, with a maximum of 25% and a minimum of 8.3% occurring after 1980 (Padgett-Flohr and Hopkins 2009). Currently, reported infections for *R. draytonii* along the coast of California show *Bd* occurring at 11 of 21 sites (52%: www. spatialepidemiology.net/bd-maps/surveillance/s_country.asp; accessed March 2010). *Bd* prevalence in the Sierra Nevada is also higher than reported for Ranidae species in the northeastern U.S. (between 15.5% and 25.7%, Longcore et al. 2007).

Our research was conducted with the aim of providing baseline information on the prevalence of *Bd* in the few *R. draytonii*

populations occurring in the Sierra Nevada. This knowledge is critical to inform managers that may consider actions to benefit conservation of the species, such as initiation of captive breeding or translocation activities, or by providing a disease profile of the area in which to recolonize the species from other populations. Monitoring of the frogs at these ponds is warranted to better understand the susceptibility of *R. draytonii* at these sites to chytridiomycosis. At this time, we have not observed mortality. Occurrence of *Bd* on sympatric species also needs to be examined, due to their potential role as disease carriers. As described in Padgett-Flohr (2008), *R. draytonii* are susceptible to *Bd* infection but remain asymptomatic and there may be a strong selection for *Bd* resistance. As a result, other species typically co-occurring with *R. draytonii* (e.g., *Rana boylii*) may be highly susceptible to cross infection. Biosecurity of these sites from incidental spread of the disease from recreational or other uses are management implications of the disease prevalence reported here. Although Padgett-Flohr and Hopkins (2010) did not find that recreational activity influenced the *Bd* status of a pond, indicating that humans via recreational activity are not likely transporting *Bd* between ponds, use of disinfection procedures and need for site quarantine are considerations given the status of the species.

Acknowledgments.—This research was conducted under USFWS Agreement # 8142080216, Agreement # 8142080215, and Agreement # 178004578.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations in the field, with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance.

Electronic submission of manuscripts is requested (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Figures can be submitted electronically as JPG files, although higher resolution TIFF or PDF files will be requested for publication. Please DO NOT send graphic files as imbedded figures within a text file. Additional information concerning preparation and submission of graphics files is available on the SSAR web site at: http://www.ssarherps.org/HRinfo.html. Manuscripts should be sent to the appropriate section editor: **Jackson D. Shedd** (crocodilians, lizards, and *Sphenodon*; jackson.shedd@gmail.com); **Charles W. Painter** (amphibians; charles.painter@state.nm.us); **John D. Willson** (snakes; hr.snake.nhn@gmail.com); and **James Harding** (turtles; hardingj@msu.edu).

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*. SSAR Herpetol. Circ. 37:1–84, available from SSAR Publications Secretary, ssar@herplit.com; for Mexico as it appears in Liner and Casas-Andreu 2008, *Standard Spanish, English and Scientific Names of the Amphibians and Reptiles of Mexico.* Herpetol. Circ. 38:1–162), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Some further comments. The role of the "Standard Names" lists (noted above) is to standardize English names and comment on the current scientific names. Scientific names are hypotheses (or at least represent them) and as such their usage should not be dictated by a list, society, or journal.

Recommended citation for notes appearing in this section is: Medina, P., and R. L. Joglar. 2008. *Eleutherodactylus richmondi*: reproduction. Herpetol. Rev. 39:460.

CAUDATA — SALAMANDERS

AMBYSTOMA TALPOIDEUM (Mole Salamander). **POLYMELIA.** Amphibian malformations have been the topic of scientific and public interest for the past decade. Naturally-occurring deformities occur in populations, but are rare, usually less than 2% of individuals (Eaton et al. 2004. J. Herpetol. 38:283–287). Herein I describe a Mole Salamander with an unusual deformity. Paedogenic Mole Salamanders were dipnetted from a permanent pond in the Whitehall Experimental Forest near the University of Georgia campus in Athens, Georgia (USA), on 11 Dec 2008. This pond contains a large population of paedogenic Mole Salamanders in most years (ca. 300). A total of 7 males and 8 females were captured. Of these, all appeared normal except one male, which had an extra right forelimb (Fig. 1). The malformed male, along with 6 normal males ('reference males'), were examined in detail; I made note of the degree of swelling of the cloaca; total length (from snout to tail tip) was measured to the nearest 0.1 cm.

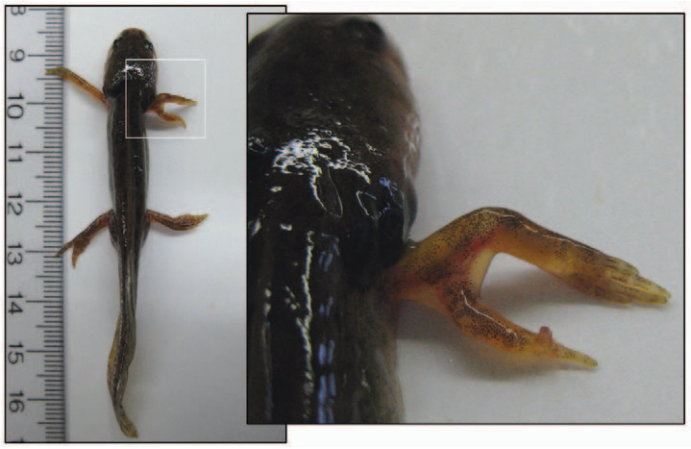

FIG. 1. Paedogenic Mole Salamander (*Ambystoma talpoideum*) with an extra forelimb on its right side. The extra limb originates from the middle part of the humerus, and has two toes (inset photo).

When examined in the lab it was clear there was an extra limb emerging from the humerus of its right forelimb (Fig. 1). The extra limb appeared to have an elbow and there were two toes. The limb was emerging from the posterior side of the right humerus, so that it trailed behind the salamander when it moved. A video of the salamander can be viewed at http://picasaweb.google.com/AndyDavisUGA/5LeggedMoleSalamander#. In the video, it appears that the extra limb did not hinder movement of the salamander, and appeared to be non-functional. The malformed male was noticeably smaller in mass and total length than most of the reference males. This male's mass was 3.0 g, average mass of the reference males was 3.5 g (± 0.3 SD); total length was 8.5 cm, average for the reference males was 9.1 cm (±0.3 SD). Though smaller than the reference males, it did have a large cloacal swelling, indicating it was in breeding condition. Three of the six reference males were also in breeding condition. Within the genus *Ambystoma*, there are scattered reports of deformities (Ouellet 2000. *In* Sparling et al. [eds.], Ecotoxicology of Amphibians and Reptiles, pp. 617–661. Soc. Environ. Toxicology Contaminants [SETAC] Press, Pensacola, Florida). Semlitsch et al. (1981. Herpetol. Rev. 12:69) reported a terrestrial adult Mole Salamander with five legs (one extra hindlimb) in South Carolina, although in that individual, the extra limb was semi-functional.

Despite only collecting 15 individuals on the sampling day, the actual frequency of malformations in this population is likely extremely small, since I have made many prior collections from this pond and others nearby (within 300 m), and have never encountered other malformed individuals. I have collected ca. 140 individuals from this and the nearby ponds, so the frequency of malformations could be less than 1% in this general area. Further, this pond is not near any source of chemical pollution, and has no history of environmental disturbance. Both of these points suggest this individual represents a "naturally occurring" deformity.

AMPHIUMA MEANS (Two-toed Amphiuma) **x** ***AMPHIUMA TRIDACTYLUM*** (Three-toed Amphiuma). **HYBRIDIZATION**. The phylogenetic relationship among *Amphiuma* species is unclear, as molecular studies have produced discordant results (Bonett et al. 2009. PLoS ONE 4[5]:e5615. doi:10.1371/journal.pone.0005615; Karlin and Means 1994. Am. Midl. Nat. 132:1–9; Weisrock et al. 2005. Syst. Biol. 54:758–777). Although these studies indicate that the three taxa, *Amphiuma pholeter*, *A. means*, and *A. tridactylum* are separate species, intermediate specimens that possess characters of both *A. means* and *A. tridactylum* have been reported (Bonett et al. 2009, *op. cit.*; Hill 1954. Tulane Stud. Zool. 12:190–214).

Amphiuma means is identified by having two toes on each limb with uniform dark brown body color, while *A. tridactylum* has three toes on each limb, a dark brown dorsum, a pale gray belly, and a dark brown throat patch. *Amphiuma means* has a geographic range from southeastern Louisiana (East Baton Rouge Parish) to Virginia, while *A. tridactylum* ranges from eastern Texas to central Alabama. Although this is a substantial range overlap (ca. 640 km), the intermediate forms with incongruent toe number or color pattern are known only from a relatively small subset of this area (Mandeville, Talisheek Bay, and Pearl River, Louisiana, 25 km max. distance). Because these intermediate individuals represent a very small portion of the population, e.g., only three of 131 specimens collected from the overlap zone were intermediates (Hill 1954, *op. cit.*), the degree of hybridization has been largely regarded as negligible.

Here, I report additional intermediate specimens from Livingston Parish, Louisiana, 75 km farther west into the zone of overlap. Three individuals were collected from a roadside ditch in Livingston Parish, Frost, Gum Swamp Rd. 8.7 km. S. jct. Hwy 42 (30.3500°N, 90.6852°W). The first (Southeastern Louisiana University, SLU 396) had uniform coloration (like *A. means*) and a toe count, following the format of Hill (1954, *op. cit.*), of Right Forelimb/Left Forelimb, Right Hindlimb/Left Hindlimb, of 2/2, 3/3. The second individual (SLU 395) had uniformly dark coloration, but three toes on each of the four limbs. The third individual (SLU 397) had pure *A. tridactylum* characters. Baker (1947. J. Tennessee Acad. Sci. 22:9–21) described seven different toe patterns, including the normal number and shape for *A. means* and *A. tridactylum*, as well as a variety of anomalies. In each of the three individual *Amphiuma* that I collected, the two-toed and three-toed morphology was typical of *A. means* and *A. tridactylum*, as shown in Baker (1947, *op. cit.*, fig. 2a, d), and not otherwise anomalous or the result of mutilation. Discovery of these new intermediate individuals suggests that the relationship between *A. means* and *A. tridactylum* may be much more complicated than previously believed. Understanding this relationship will require extensive genetic sampling in the zone of overlap.

Submitted by **CLIFFORD L. FONTENOT, JR.**, Department of Biological Sciences, Southeastern Louisiana University, Hammond, Louisiana 70402, USA; e-mail: cfontenot@selu.edu.

ANEIDES AENEUS (Green Salamander). **RED PROTRUSIONS ON BODY.** *Aneides aeneus*, a crevice-dwelling species, is strictly terrestrial and the genus is considered

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. *Aneides aeneus* from northeastern Alabama showing isolated red protrusions.

to be the most terrestrial among plethodontids of the eastern United States (Gordon 1952. Amer. Midl. Nat. 47[3]:656–701). Like many amphibian species, *A. aeneus* populations have suffered drastic declines. Hafer (1992. M.S. thesis, Clemson University, Clemson, South Carolina) indicated that during the prior 15 years *A. aeneus* had disappeared from 78% of its known range. Currently, in ten of the thirteen states in which they are known to occur, *A. aeneus* are in jeopardy.

From May 2005 to December 2006 *A. aeneus* was studied at three sites in northeastern Alabama. During this study 26 (11.2%) of the 233 total collected individuals were observed having a series of red, circular, raised, capillary-filled protrusions (Fig. 1). Of the 26 individuals with protrusions, 21 (80.8%) were adults and 5 (19.2%) were sub-adults. No juveniles were observed with protrusions at any site. Occurrence of these protrusions ranged from 1 to 7 per individual.

The presence of these protrusions is new to *A. aeneus*, and possibly to terrestrial salamanders. Potentially, this occurrence is a major concern for a species that is already experiencing population declines. Other species of amphibians—*Eurycea longicauda longicauda, Notophthalmus viridescens viridescens, Pseudotriton ruber ruber, Rana clamitans melanota*, and *R. palustris*—were observed in crevices where *A. aeneus* was encountered. However, protrusions were not seen on any of these organisms. This might indicate that *A. aeneus* is more sensitive to or is experiencing more environmental stressors than sympatric amphibian species. Special attention needs to be given to other populations of *A. aeneus* to discover if these protrusions are an isolated event in northeastern Alabama or if they occur elsewhere in the species' range. Additional research is needed to determine the cause of these protrusions and their impact to individual salamanders.

Submitted by **SARA E. VIERNUM**, Department of Biology, Jacksonville State University, Jacksonville, Alabama 36265, USA; e-mail: sviernum@yahoo.com.

DESMOGNATHUS AENEUS (Seepage Salamander). **HABITAT.** Current species accounts for *Desmognathus aeneus* are derived mostly from observations made from the core of this species' range in the lower elevations of the Blue Ridge physiographic province of the Southern Appalachians, and habitat descriptions from this region converge on the common theme of moist mountain seepage areas in mesic hardwood forests (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, 575 pp.; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Press, Washington, D.C., 587 pp.). Outside of this region, *D. aeneus* is less common and there is less information on its habitat associations. This may eventually lead to a lack of understanding of this species' distribution, a false impression of its rarity, and has misdirected our own attempts to find these salamanders.

Here, we compile habitat information from three sites outside of the Blue Ridge, one of which represents an undocumented habitat type for this salamander. The Talbot Co., Georgia site is a recent range extension for this salamander into the Pine Mountain Ridges (Graham 2009. Herpetol. Rev. 40:232–233) in the Piedmont physiographic province, known for its unique herpetofaunal assemblage (Graham et al., *in press*). Of the three sites we examined, this site most closely matches the described habitat types for this species, although it is noteworthy how far south this site is (32.88055°N, 84.50418°W; WGS 84). It is seepage along a wet rock face on a north-facing slope with an overstory of Tuliptree, American Holly, Red Maple, Chestnut Oak, and Longleaf Pine, with a Mountain Laurel/Carolina Rhododendron shrub layer, and an herbaceous component of Trailing Arbutus, *Galax*, sphagnum, and other mosses. Other salamanders in the vicinity are *Desmognathus cf. apalachicolae*, *Gyrinophilus porphyriticus*, *Eurycea cirrigera*, and *Plethodon websteri*. Cheaha Mountain is in the Talladega Uplands of the Piedmont (Cleburne Co., Alabama), and has long been known to support populations of this species (Rubenstein 1969. J. Herpetol. 3:33–47). However, the seepage where we located this particular population (33.471962°N, 85.822916°W; WGS 84) appeared to be a typical, mucky seepage of the Piedmont and not especially montane in character. The overstory is composed of Tuliptree, White Oak, and Mockernut Hickory, with the shrubs Virginia Sweetspire and Mountain Laurel. Royal Fern and other ferns are present. Other salamanders include *D. conanti* and *P. glutinosus*. The third site in Bibb Co., Alabama, is a lowland gum swamp in the Fall Line Hills of the Coastal Plain physiographic province (32.906922°N, 87.392005°W; WGS 84). It is adjacent to a beaver dam marsh, an atypical site for this species. The dominant tree is Swamp Blackgum, along with Sweetbay, Red Maple, Tuliptree, American Holly, and Loblolly Pine. The shrub layer is Dog Hobble, and herbaceous plants include netted and Virginia Chain Fern, with abundant sphagnum moss. Salamander associates include *Pseudotriton ruber*, *P. montanus*, *D. conanti*, and *Plethodon mississippi*.

These collection trips were partially supported by NIH grant R01-A149724 to T. Unnasch under Georga collection permit 29-WBH-08-8.

Submitted by **SEAN P. GRAHAM**, Auburn University, Department of Biological Sciences, 331 Funchess Hall, Auburn University, Alabama 36849, USA (e-mail: grahasp@auburn.edu); and **WALTER H. SMITH**, Ecology, Evolution, and Systematics Section, Department of Biological Sciences, University of Alabama, Tuscaloosa, Alabama 35487, USA.

DESMOGNATHUS FOLKERTSI (Dwarf Black-bellied Salamander). **REPRODUCTION.** *Desmognathus folkertsi* is a recently described species (Camp et al. 2002. Herpetologica 58:471–484) whose reproductive biology is partially known (Camp and Marshall 2006. Southeast. Nat. 5:669–684). Egg clutches, however, have never been described. During the summer of 2009, we discovered three separate egg clutches and associated attending females of this species in northern Georgia, USA. Following measurements, all cover stones were replaced and females released beneath them.

The first clutch (found 11 July 2009), consisting of 24 eggs, was discovered at 34.6447222°N, 83.3377778°W in a small (1.5 m wide streambed) tributary of the Little Toccoa Creek in Stephens Co., Georgia. The nesting cavity lay between two flat stones, the upper stone having a flat surface area of 100 mm x 250 mm and a thickness of 25 mm. The eggs were attached singly to the upper surface of the lower stone and were submerged in a very shallow (3 mm) trickle of water. The attending female was 65 mm SVL.

The second clutch (19 July 2009) contained 36 eggs and was located at 34.8216667°N, 83.7333333°W in a small (2.1 m streambed) tributary of the Hiwassee River in Towns Co., Georgia. The nesting cavity was beneath a flat stone (upper surface 160 mm x 150 mm; thickness 71 mm) over a floor of gravelly sand. The eggs, all newly laid, were attached singly and in distinct rows on the lower surface of the overlying stone. They ranged 4.0─4.5 mm in diameter and were 31 mm deep in running water. The attending female was 71 mm SVL.

The third clutch (22 July 2009) consisted of 38 eggs. It was located at 34.6683333°N, 83.3211111°W in Rothwell (Walker) Creek (ca. 5 m streambed) in Stephens Co., Georgia. The eggs were beneath a flat stone (upper surface 190 mm x 135 mm; thickness 40 mm) overlying gravelly sand and were attached singly to the lower surface of the cover stone. They had distinct embryos and measured an average of 6.1 mm in diameter. The eggs were all in running water at a depth of 30 mm. The attending female was 66 mm SVL.

The timing and manner of clutch-laying that we report herein indicate that oviposition and nest attendance in *D. folkertsi* is largely typical of *Desmognathus* (Petranka 1998. Salamanders of the United States and Canada, Smithsonian Institution Press, Washington, DC). The exception is the first clutch, whose eggs were laid on the floor of the nesting cavity instead of the roof. This is unusual for members of this genus, but the presence of another stone rather than sand or gravel as a floor may have been a contributing factor.

Submitted by **CARLOS C. CAMP** (e-mail: ccamp@piedmont.edu), **JOSHUA A. MITCHEM**, and **T. JACOB KRIEGER**, Department of Biology, Piedmont College, Demorest, Georgia 30535, USA; and **CHRISTOPHER E. SKELTON**, Department of Biological and Environmental Sciences, Georgia College and State University, Milledgeville, Georgia 31061, USA.

DESMOGNATHUS QUADRAMACULATUS (Black-bellied Salamander). **RECORD CLUTCH AND EGG SIZE.** *Desmognathus quadramaculatus*, a common resident of streams in the southern Appalachian Mountains, has been the subject of numerous studies of reproductive biology (Bruce 1996. Copeia 1996:783–790). The maximum size reported for field clutches of this species is 56 eggs (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC). Reported egg diameter is 3.9 mm (Tilley and Bernardo 1993. Herpetologica 49:154–163). On 19 July 2009, we discovered a nest attended by a female at 34.8208333°N, 83.735°W in a small (2.7 m wide streambed) tributary of the Hiwassee River in Towns Co., Georgia, USA. The clutch contained 82 eggs that averaged 7.0 mm diameter; all had well developed embryos. The eggs were submerged, suspended in running water that was 40 mm deep. Each egg was individually attached to the lower surface of an emergent, flat stone that measured 293 mm x 234 mm in upper surface area and was 24 mm thick. The attending female measured 97 mm SVL. The cover stone was replaced and the female released beneath it following measurements.

Both clutch size and egg diameter are significantly greater than previously reported. The large size and number of eggs are not unexpected, however. Both egg and clutch size is positively related to SVL in this species (Tilley 1968. Evolution 22:806–816; Camp et al. 2000. Can. J. Zool. 78:1712–1722), and populations from the Hiwassee River drainage contain the largest individuals known (Camp et al. 2002. Herpetologica 58:471–484).

PSEUDOEURYCEA ORCHIMELAS (Tuxtlan Worm Salamander). **DEFENSIVE BEHAVIOR**. *Pseudoeurycea orchimelas* is known to flip violently and unpredictably, propelling itself by rapidly coiling and uncoiling the body when handled. By using its long tail as a launching device, these salamanders may easily flip out of the hand and disappear into the leaf litter (Brodie et al. 2002. Herpetologica 58:201). Here we present another defensive behavior observed on this species.

On 5 July 2008, we found a *P. orchimelas* (80 mm total length) under a rock (22.6ºC, 99% relative humidity) in a tropical rain forest fragment at Los Tuxtlas, Veracruz, México (18.5656528°N, 94.1268722°W, 600 m elev). When discovered, the first reaction of the salamander was to flee among the leaf litter but was immediately captured. Once in the hand of one of the authors it clasped its limbs along the body and remained straight and motionless (resembling a twig) while it was measured and examined, which took about two min. It was then placed on the leaf litter to be photographed and after a minute it had returned to a natural position and started moving again.

Submitted by **ALFONSO HERNÁNDEZ-RÍOS**, Laboratorio de Ecología, Facultad de Estudios Superiores Iztacala, Universidad Nacional Autónoma de México, Estado de México 54090, México (e-mail: fermento_etereo@hotmail.com); and **HECTOR SHIZI LUNA-ALCANTARA**, Laboratorio de Herpetología, Instituto de Biología, Universidad Nacional Autónoma de México, Distrito Federal 04510, México.

PSEUDOTRITON MONTANUS DIASTICTUS (Midland Mud Salamander). **PARASITES.** Little is known about the parasites of *Pseudotriton montanus*. Rankin (1937a. Ecol. Monogr. 7:169–269; 1937b. J. Parasitol. 23:29–42) reported *Allocreadium pseudotritoni*, *Gorgoderina bilobata*, larval *Physaloptera* sp., and *Hannemania dunni* from Eastern Mud Salamanders (*P. m. montanus*) from North Carolina. Other reports include Catalano et al. (1982. Ohio J. Sci. 82:120–128) who documented *A. pseudotritoni* and *Megalodiscus temporatus* from Midland Mud Salamanders from Ohio, and Nickol and Heard (1973. Proc. Helminthol. Soc. Washington 40:204–208) who found *Fessisentis necturorum* in larval *P. m. montanus* from Georgia. Here we report a new host and distributional record for an endo- and ectoparasite of *P. m. diastictus* from Kentucky.

One *P. m. diastictus* (45 mm SVL, female) was collected by hand on 30 July 2007 from Garrard Co., Kentucky, 6.5 km NE of Crab Orchard (37.49160°N, 84.44293°W). It was euthanized with a dilute chloretone solution. Chiggers (*H. dunni*) were excised from skin lesions and processed per methods of McAllister et al. (1995. J. Helminthol. Soc. Washington 62:150–156). In addition, a midventral incision was made to expose the entire length of the digestive tract. Two trematodes (*A. pseudotritoni*) were recovered from the small intestine, stained with Delafield's hematoxylin, and mounted with Canada Balsam. Specimens are deposited in the United States Parasite Collection (USNPC), Beltsville, Maryland as USNPC 100476 (*A. pseudotritoni*) and 101115 (*H. dunni*). A host voucher is deposited in the Arkansas State Herpetological Museum (ASUMZ), State University, Arkansas as ASUMZ 30827.

We report a new distributional record for the trematode *A. pseudotritoni*, previously reported from 2 of 3 (67%) *P. m. montanus* from Durham Co., North Carolina (Rankin 1937, *op. cit.*) and 5 of 9 (56%) *P. m. diastictus* from Adams, Scioto, and Vinton counties, Ohio (Catalano et al. 1982, *op. cit.*). In addition, a new host record for the chigger *H. dunni* is documented for *P. m. diastictus*, previously reported from 1 of 3 (33%) *P. m. montanus* from Durham Co., North Carolina (Rankin 1937, *op. cit.*). We suggest additional specimens of *P. m. diastictus* from Kentucky be examined for helminths in an attempt to provide comparative prevalence and parasite intensities.

RICHTER**, Department of Biological Sciences, Eastern Kentucky University, Richmond, Kentucky 40475, USA (e-mail: stephen.richter@eku.edu).

ANURA — FROGS

AGALYCHNIS MORELETII (Morelet's Frog). **PREDATION.** *Agalychnis moreletii* is a critically endangered treefrog surviving only in small pockets in northern Central America (IUCN RedList). Here I report what appears to be a common predator of this frog in central Belize.

On 19 June 2002, I witnessed a cat-eyed snake *Leptodeira septentrionalis* eating a large female *A. moreletii*. On several further occasions that summer and in the years following, at various breeding aggregations across the region, I witnessed *A. moreletii* eggs and adults being depredated by *L. septentrionalis*, indicating that eggs and adults of *A. moreletii* are likely a common item in the diet of *L. septentrionalis*. In 2008, I found two frogs at one breeding aggregation with what appeared to be fang marks in their backs. At the sites where these observations were made, *L. septentrionalis* is a common snake, with several individuals being observed at *A. moreletii* choruses each night. Although *L. septentrionalis* is known to feed on frog eggs (Lee 2000. A Field Guide to the Amphibians and Reptiles of the Maya World. Cornell Univ. Press, Ithaca, New York. 416 pp.), feeding on *A. moreletii* has not been previously documented.

This work was supported by Cleveland State University and the Columbus Zoo and Aquarium.

AMIETOPHRYNUS CAMERUNENSIS (Cameroon Toad). **DEFENSIVE BEHAVIOR**. Frogs show a variety of defense and predator avoidance behaviors (e.g., aposematic coloration, cryptic coloration, chemical defenses). Use of parotid secretions in toads as a means of defense is well known, as these glands contain poisonous or noxious secretions (Vitt and Caldwell 2009. Herpetology, 3rd ed. Academic Press, San Diego, California. 720 pp.). Herein I report an observation from the Mawne River Forest Reserve in western Cameroon. An individual *Amietophrynus camerunensis* was collected on 27 September 2007 in a primary rainforest (5.87765°N, 9.5148833°E; ca. 132 m elev.) and deposited in the collection of the Zoologisches Forschungsmuseum Alexander Koenig, Bonn (ZFMK 87820). When touched on the back the toad assumed a specific position and its parotids secreted a small amount of poison (Fig. 1). The toad dropped its head, lifted the abdomen and formed a "bow" with its back, its parotids being orientated towards the opponent. After a while the toad interrupted this position and started to hop away until it was disturbed again. The specimen repeated

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Defensive behavior of the Cameroon Toad, *Amietophrynus camerunensis.*

the behavior and assumed the same position, oriented towards its opponent. After a couple of repetitions, the behavior became less distinct and the toad only dropped its head without lifting the abdomen. The same response to touch was later observed in another individual (ZFMK 87822; 3 Oct 2007, Cameroon, near Amebishu; 5.8977667°N, 9.55825°E; ca. 166 m elev.). A similar behavior was reported for *Rhinella* cf. *crucifer* (Toledo 2004. Herpetol. Rev. 35:370–371). In contrast, *R.* cf. *crucifer* arranged either its lifted head or lifted abdomen independently towards the opponent depending on the position of the touch on the front or hind of the dorsum. As in *R.* cf. *crucifer* the behavior in *A. camerunensis* indicates an enlargement of the surface towards the predator, as well as a more appropriate positioning of the parotids, both suggesting a means of deterrence.

Thanks to the Cameroonian authorities for permits to conduct this research (Ministry of Research and Innovation: N049/MINRESI/B00/C00/C10/C12; Ministry of Forestry and Wildlife: N0836/PRBS/MINFOF/SG/DFAP/SDVEF/SC) and the German Exchange Service DAAD for financial support.

ANAXYRUS BOREAS (Western Toad). **ADVERTISEMENT VOCALIZATION**. The presence of advertisement vocalization (mating or breeding calls) in the Western Toad species group (*Anaxyrus* [*Bufo*] *boreas*) has not been well established. It is generally accepted that Western Toads lack vocal sacks (Black and Brunson 1971. Great Basin Nat. 31:109–113; Hammerson 1999. Amphibians and Reptiles in Colorado. 2nd ed. Colorado Div. Wildlife Publ., Univ. Press Colorado, Niwot, Colorado) and have lost their advertisement calls (Blair 1972. *In* W. F. Blair [ed.], Evolution in the Genus *Bufo*, pp. 93–101. Univ. Texas Press, Austin, Texas; Marco et al. 1998. Anim. Behav. 55:1631–1635), although there are reports to the contrary (Awbrey 1972. Copeia 1972:579–581; Cook 1983. Natl. Museums of Canada Publ. Nat. Sci., 3, Ottawa, Ontario). Males will emit 'release calls' when grasped by another toad or a researcher, consisting of a series of short chirps that identify the individual as a male and trigger a release response in males attempting amplexus (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. Press Idaho, Moscow, Idaho. 332 pp.). Males might also give a release-like call when encountering other males (encounter call) without attempting amplexus, sometimes resulting in 'chorus-like' group vocalizations (Black and Brunson 1971, *op. cit.*). These choruses might act to attract females from the surrounding habitat, but this has not been clearly demonstrated.

A Boreal Toad (*A. b. boreas*) breeding congregation was observed in a wetland southeast of Whitecourt, Alberta, Canada (53.9822286962005°N, 115.46401912003°W; NAD 83) in 2007, 2008, and 2009. Toads usually began spawning in mid-to-late May and continued through June or later. I present video and audio evidence clearly illustrating Boreal Toads engaging in advertisement vocalization, recorded 10 June 2009. Several video and audio clips documenting this breeding congregation can be viewed at http://flash.lakeheadu.ca/~zlong/, or obtained by contacting the author. The primary clip (bts_presentation.mov) features a single male toad vocalizing in a series of rapid, extended trills characteristic of toad advertisement calls. The inflated external median subgular vocal sac of the male is clearly visible moving with the pulses of the vocalization. Other advertising males can be heard in the background, engaging in what sounds like call/reply exchanges. This is a clear example of display behavior, and not release or encounter vocalization.

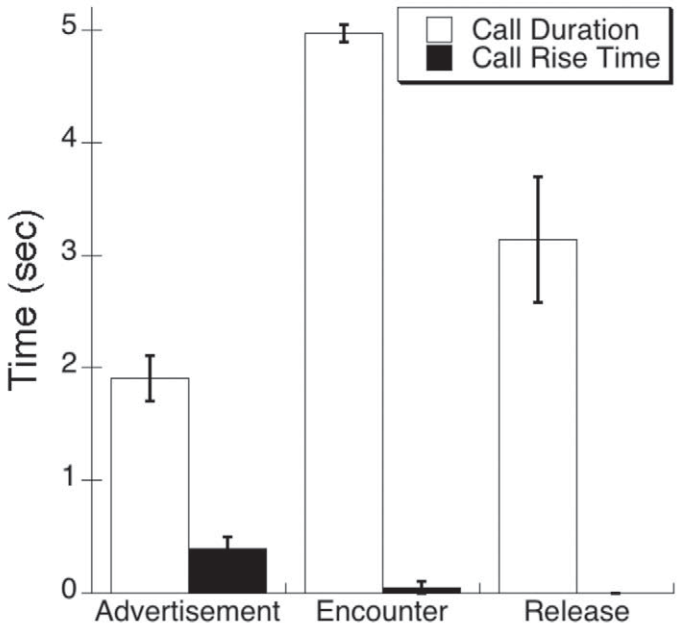

FIG. 1. Mean call duration and call rise time by vocalization type. Error bars represent standard error. Figure uses non-transformed data.

Waveform analysis was conducted on four advertisement vocalizations recorded near Whitecourt. Call duration and call rise time was measured for each discrete vocalization. Within each call, pulse duration, pulse rise time, and interpulse intervals were

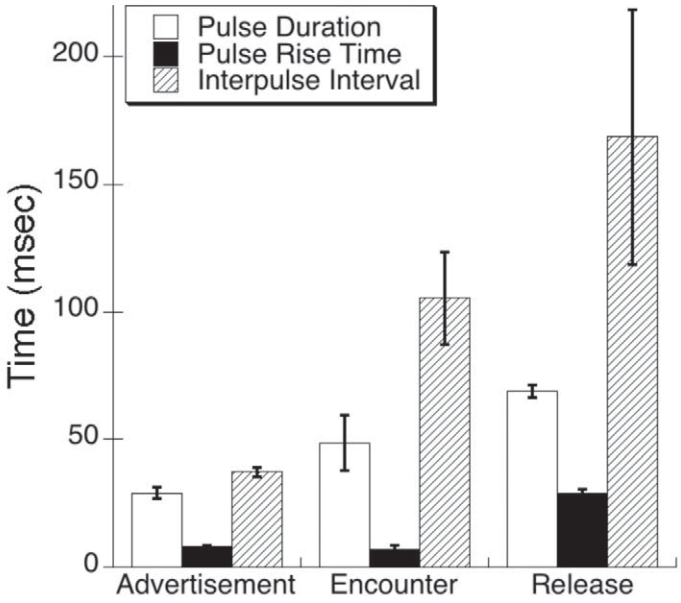

FIG. 2. Mean pulse duration, pulse rise time and interpulse intervals by vocalization type. Error bars represent standard error. Figure uses non-transformed data.

measured for five randomly selected, sequential, mid-call pulses. The Alberta recordings were compared to two encounter calls and two release calls taken with permission from CaliforniaHerps.com (2009*a*. http://www.californiaherps.com/frogs/pages/b.b.boreas.sounds.html. Accessed 28 Oct 2009; http://www.californiaherps.com/frogs/pages/b.b.halophilus.sounds.html. Accessed 28 Oct 2009) to serve as a point of reference. Analysis of variance was conducted on $\log_{10}$-transformed data to test for differences in waveform characteristics between the three call types ($\mu = 0.05$).

The advertisement vocalizations recorded in Alberta were shorter ($F_{2,5} = 18.080$, $P < 0.01$), but displayed the longest call rise time ($F_{2,5} = 10.406$, $P = 0.02$) (Fig. 1). The advertisement calls also had the shortest pulse duration ($F_{2,5} = 15.298$, $P < 0.01$) and interpulse interval ($F_{2,5} = 21.798$, $P < 0.01$) (Fig. 2). Advertisement and encounter calls displayed similar pulse rise times, both values being lower than that for release calls ($F_{2,5} = 57.859$, $P < 0.01$) (Fig. 2).

Although analyses were conducted on a small unbalanced dataset, these data strongly suggest that Boreal Toad vocalizations recorded in Alberta are indeed unique and structurally different from encounter and release calls previously described for the Western Toad species group. Combined with behavioral observations supported by video evidence, I believe that these were advertisement vocalizations. The function of these calls has not been demonstrated, but they likely serve to attract toads from the surrounding habitat, and advertise individual fitness. This has been documented in *A. americanus* through a correlation between body size and dominant call frequency (Howard and Young 1998. Anim. Behav. 55:1165–1179). The geographic range of vocal Western Toad populations remains uncertain.

I thank P. Gilhooly for field assistance, G. Nafis for permitting the use of his audio recordings, Waterhen Film Production Ltd. for donating equipment as well as dubbing and editing services, and J. Burke, S. Hecnar, M. Lannoo, and V. Kinney for reviewing this note.

BATRACHYLA TAENIATA (NCN). **BODY TEMPERATURE.** *Batrachyla taeniata* inhabits temperate forests in southern Chile, from the province of Aconcagua and relict forests of Quintero to Chiloé and Aysén (Rabanal and Núñez 2008. Anfibios de los Bosques Templados de Chile. Universidad Austral de Chile, Valdivia, Chile. 206 pp). Almost nothing is known about amphibian thermoregulation in Chilean species, therefore the purpose of this note is to provide information on the thermal ecology of *B. taeniata*. We investigated the relationship between cloacal temperature (T_b), substrate temperature (T_s), and air temperature (T_a), and their relationship to body size of these frogs under field conditions.

Twenty-six females and 22 adult males were collected at Las Quemas (41.5°S, 79.15°W; 28 m elev.) in the Province of Llanquihue during March 2009. This locality is in the hygromorphic phytogeographical region, characterized by a temperate climate with rainfall throughout the year. Immediately after capture T_b, T_s, and T_a were recorded to +0.01°C). Frogs were weighed (g) and measured (SVL, mm). Data are shown as mean ± SD.

The mean T_b of females was 10.34ºC ± 0.79 (range 8.9–11.7ºC) and males was 10.38ºC ± 0.62 (range 9.3–12.5ºC). Because no significant differences were found between sexes in T_b ($t_{46} = -0.19$, $p = 0.85$), all data were pooled. The field T_b was positively correlated with T_a ($r^2 = 0.94$, $p < 0.0001$) and T_s ($r^2 = 0.89$, $p < 0.0001$). There was no observed association between T_b and body length ($r^2 = 0.04$, $p = 0.16$) or weight ($r^2 = 0.058$, $p = 0.09$).

Our results suggest that *B. taeniata* is a thermoconformist under field conditions. According to other studies, frogs have little ability to control body temperature because of a compromise between thermal conditions and water balance, which reduces the ability of these animals to thermoregulate behaviourally (Seebacher and Alford 2002. J. Herpetol. 36:69–75). However, this physiological performance could be related to saving time and energy for other behaviors (Labra and Vidal 2003. *In* F. Bozinovic [ed.], Fisiología Ecológica y Evolutíva, pp. 207–224. Ediciones Universidad Católica de Chile, Santiago, Chile).

We thank C. Vargas for field assistance, M. Olivares for laboratory help, and L. Eaton for assistance with the manuscript.

BOKERMANNOHYLA SAXICOLA (NCN), ***SCINAX CURICICA*** (Lanceback Treefrog), ***SCINAX SQUALIROSTRIS*** (Snouted Treefrog), ***TRACHYCEPHALUS MESOPHAEUS*** (Golden-eyed Treefrog), and ***ELACHISTOCLEIS* SP.** (Oval Frog). **MORPHOLOGY**. Malformation in frogs is known for adults (Blaustein et al. 2003. Front. Ecol. Environ. 1[2]:87–94) and tadpoles (Piha et al. 2006. Environ. Toxicol. Chem. 25[12]:3164–3170). In tadpoles, malformations may occur in all body parts (body, head, eyes, tails, and limbs). For tails, recorded malformations are two tails (Budischak et al. 2008. Environ. Toxicol. Chem. 27[12]:2496–2500), tail with a torsion at the distal and proximal regions (Haddad et al. 1990. Rev. Bras. Biol. 50[3]:739–744), and bifurcated or forked tails (USFWS 1999. Standard Operating Procedures for Abnormal Amphibian Surveys; Wright 2002. Life Histories of the Frogs of Okefinokee Swamp, Georgia, p. 307). The most common referred causes suggested for malformations (including those in post-metamorphic anurans) are injuries (Morgan 1990. Biol. Bull. 2[3]:111–119), parasites (Johnson et al. 2002. Ecol. Monogr. 72[2]:151–168), viral infection (Burton et al. 2008. Vet. J. 177:442–444), fungal infection (Blaustein et al. 2005. Cons. Biol. 19[5]:1460–1468), UV-B exposure (Uitregt et al. 2007. Glob. Change Biol. 13[6]:1114–1121; Licht 20003. BioScience 53[6]:551–561), environmental contamination from pesticides or other pollutants (Brunelli et al. 2009. Aq. Toxicol. 91[2]:135–142; Sayim 2008. Turk. J. Zool. 32:99–106, Paisio et al. 2009. J. Hazard. Mat. 167:64–68; Taylor et al. 2005. Environ. Health Persp. 113[11]:1497–1501), and natural hybridization (Haddad et al. 1990. Rev. Brasil. Biol. 50[3]:739–744).

During fieldwork between 1972 and 1974 five tadpoles were

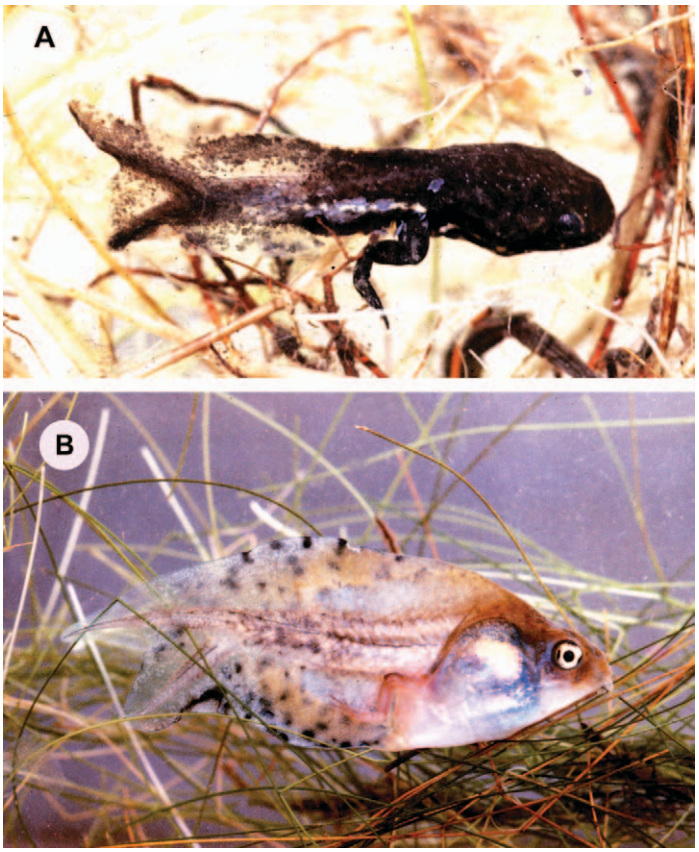

FIG. 1. Tadpoles of *Elachistocleis* sp. (A) and *Scinax curicica* (B) with bifurcated tails.

obtained that had bifurcated tails: one microhylid, *Elachistocleis* sp. (Fig. 1A) and four hylids, *Bokermannohyla saxicola* (ZUEC 15451), *Scinax curicica* (ZUEC 15575; Fig. 1B), *S. squalirostris* (ZUEC 15452), and *Trachycephalus mesophaeus* (ZUEC 16252). The microhylid and the first three hylids were collected at Serra do Cipó, municipality of Jaboticatubas, state of Minas Gerais, SE Brazil, whereas the fourth hylid was collected in the municipality of Ubatuba, state of São Paulo, SE Brazil. These specimens are in the Amphibian Collection of the Museu de Zoologia "Prof. Adão José Cardoso" (ZUEC), Universidade Estadual de Campinas, Campinas, Brazil. The swimming ability of the fork-tailed tadpoles apparently was unaffected or little affected by the malformation, although the mid-water hovering tadpole of *S. curicica* might be hampered in its foraging (I. Sazima, pers. comm.).

This type of malformation (forked tail) has been classified as superficial as it may be the result of healed injuries (Morgan 1990, *op cit.*; USFWS 1999, *op cit.*). However, we cannot rule out the possibility of the influence of one or multiple environmental contaminants for the *T. mesophaeus* tadpole, as it was collected in a drainage ditch. The remaining tadpoles were collected in relatively pristine habitats.

We are grateful to I. Sazima for revising the manuscript and for providing unpublished data. We also thank FAPESP for grants (2008/50325-5) and scholarships (2008/09770-5 and 2008/52847-9).

Submited by **NELSON RODRIGUES SILVA** (e-mail: nelsonrodrigues2701@yahoo.com) and **LUÍS FELIPE TOLEDO** (e-mail: toledolf2@yahoo.com), Museu de Zoologia "Prof. Adão José Cardoso," Instituto de Biologia, Universidade Estadual de Campinas, Rua Albert Einstein s/n, Campinas, São Paulo, CEP 13083-863, Brazil.

BUFO DEBILIS (Green Toad). **MORTALITY**. Little is known about the negative fitness costs of reproduction on amphibians in arid regions. Herein we document a mass anuran mortality event of unknown cause(s), consisting mainly of *Bufo debilis* but also including other bufonids and pelobatids.

We sampled Chihuahuan Desert wetlands on Bureau of Land Management land for water parameters during July 2009. We found a large number of dead bufonid and pelobatid anurans at a desert playa that has an earthen cattle tank excavated within its perimeter (UTM 13S 0317867, 3565407; NAD 27). Monsoonal rains had elicited a breeding event during 4–5 July 2009, and an additional rain on 10–11 July likely prolonged the breeding event. *Bufo debilis* were present the first evening after the rain, but were not calling with the rest of the chorus. We returned on 14 July and found a large number of dead *B. debilis*, *B. cognatus*, *Scaphiopus couchii*, *Spea bombifrons*, and *Sp. multiplicata*). We then formally surveyed for bodies 15 July 2009 walking transects across the wetland and being meticulous to not double-count individuals. Carcasses appeared to be distributed randomly along the shore and around grass clumps in the water. There were likely more individuals initially dead on the upland surrounding the playa, but we sampled several days after the rain event and many, if not most, of the dead individuals on land were likely eaten or carried away. We searched the wetland (140 m x 80 m) and found 21 *B. debilis*, two *B. cognatus*, and three unidentified pelobatids dead, floating around the edges of the wetland and adjacent to grass clumps within the wetland. We had two carcasses (*B. cognatus* and *S. couchii*) tested for the presence of *Batrachochytrium dendrobatidis* (*Bd*) using PCR at Texas Tech University. Swabs were taken from the toes, and dorsal and ventral surfaces of each frog. No evidence of *Bd* infection was found. However, it should be noted that the sample size was small and the individuals sampled were degrading by the time we collected them in the field.

This is manuscript number T-9-1183, College of Agricultural Sciences and Natural Resources, Texas Tech University, Lubbock, Texas.

BUFO TERRESTRIS (Southern Toad). **PREDATION**. While conducting a road survey at ca. 2100 h on 3 July 2009 in Okaloosa Co., Florida (USA), we encountered a juvenile Black-crowned Night-Heron, *Nycticorax nycticorax*, walking along a dirt road. The bird was apparently using the road as a foraging corridor and feeding on toads and other prey items. As we watched, the heron captured and began to consume a *Bufo terrestris*. We were unable to determine if the heron would have ingested the toad

as all parties were startled by the appearance of an individual in the course of a military exercise. Approximately 45 minutes later we encountered what was likely another juvenile Black-crowned Night-Heron also foraging on the road. We observed the bird capture and consume another toad; likely a *B. terrestris* although we were unable to confirm identification due to the small size of the toad. Our observations indicate that Black-crowned Night-Herons are predators of *B. terrestris* and roads may facilitate avian predation on anurans.

CHIROMANTIS VITTATUS (Burmese Bushfrog). **COLORATION.** *Chiromantis vittatus* is a small rhacophorid frog distributed from northeastern India, Myanmar, Thailand, Laos, Cambodia, and Vietnam and southern China (Frost 2009. Amphibian Species of the World: an Online Reference. Version 5.3 http://research.amnh.org/herpetology/amphibia/). The typical dorsal color pattern of *C. vittatus* is yellowish to violet brown, with a series of indistinct violet brown stripes or spots (Bourret 1942. Les Batrachiens de l'Indochine. Hanoi, l'Institute Océanographique de L'Indochina, Hanoi. 547 pp.; Taylor 1962. The Amphibian Fauna of Thailand. Univ. Kansas Sci. Bull. 43:267–599; pers. obs.). During amphibian surveys in Prey Long, Kratie Province, Cambodia (13.074817ºN, 105.807267ºE; 166 m elev.), we observed a single male *C. vittatus* displaying a striking pale yellow dorsum with distinct, dark brown reticulations on all dorsal surfaces with the exception of pale yellow lateral stripes (Fig. 1, AM R 171914). Although the species displayed some color variation at Prey Long, with some individuals being uniformly pale brown or yellow and some displaying stripes or faint reticulations, of several hundred individuals observed at the site, this was the only individual displaying such distinct and unusual coloration. As such, this coloration is likely a random mutation, and not a color variant.

DENDROPSOPHUS MINUTUS (Lesser Treefrog). **PREDATION.** Numerous authors have reported the predation of tadpoles and adult anurans principally by snakes, leeches, insects, and spiders (Toledo 2005. Herpetol. Rev. 36:395–400). *Dendropsophus minutus* is a small, nocturnal, and common hylid treefrog distributed widely in South America (Frost 2007. http://research.amnh.org/herpetology/amphibia). On 22 Sept 2001 we found a young female spider, *Ancylometes concolor* (Ctenidae) capturing and eating an adult *D. minutus* in vegetation around the margin of an artificial pond at Sucupira Experimental Farm/EMBRAPA (15.52ºS, 48.00ºW), located southwest of Brasília, Brazil in a core area of Cerrado biome. Spiders of the genus *Ancylometes* are reported to prey on *D. minutus* in the Amazonian region (Bernarde et al. 1999. Biociências 7:199–203; Menin et al. 2005. Phyllomedusa 4:39–47) but this is the first report of such predation in the Cerrado biome. The spider was deposited in the Coleção de Aracnídeos da Universidade de Brasília, Brasília, Brazil (DZUB 1289).

Submitted by **ADRIANA BOCCHIGLIERI**, Programa de Pós-graduação em Ecologia, Universidade de Brasília, 70910-900, Brasília, DF, Brazil (e-mail: adriblue@hotmail.com); **ANDRÉ FARIA MENDONÇA**, Departamento de Pós-graduação em Zoologia, Museu Nacional, Universidade Federal do Rio de Janeiro, 70919-970, Rio de Janeiro, RJ, Brazil; and **PAULO CÉSAR MOTTA,** Departamento de Zoologia, Universidade de Brasília, 70910-900, Brasília, DF, Brazil.

HYLA CINEREA (Green Treefrog). **MORPHOLOGY.** In most anurans mate attraction is facilitated by acoustic communication, and males have an elastic vocal sac that inflates and deflates with each call (Duellman and Trueb 1994. Biology of Amphibians. John Hopkins Univ. Press, Baltimore, Maryland). This vocal sac can sometimes be damaged or deformed, often with catastrophic consequences for the affected male (McCallum et al. 2001. Herpetol. Rev. 32:248–249).

On 14 June 2009 we captured an amplexed pair of *Hyla cinerea* at a pond at Beechwood Fish Hatchery in central Louisiana. The male had a vocal sac that was stuck half inflated, and had an additional large, air-filled "hump" on his back that extended all the way from the head to the vent (Fig 1). After separating the male from the female, he began to produce several advertisement calls. The male stopped calling before call recordings for detailed acoustic analysis could be obtained, but to an experienced observer, the calls did not sound different from calls produced by frogs with normal vocal sacs. The male did not seem to suffer major negative consequences despite the extent of the deformity. His movements seemed relatively unimpaired by the extended vocal and dorsal sacs, and he was in good body condition, suggesting that he was capable of catching prey and feeding

FIG. 1. Adult male Green Tree Frog (*Hyla cinerea*) with abnormal vocal and dorsal sacs.

normally. He was also able to call and enter amplexus, although it is impossible to verify whether he attracted the female himself or found her via satellite behavior. This alternative mating tactic—where silent males intercept females attracted by calling males—is frequently observed in *Hyla cinerea* (Perrill et al. 1978. Science 200:1179–1180). The male was released at the point of capture.

Submitted by **GERLINDE HÖBEL**, University of Wisconsin-Milwaukee, Department of Biological Sciences, Lapham Hall, Milwaukee, Wisconsin 53201, USA; and **ALEXANDER SLOCUM,** 3358 N Bartlett Ave, Milwaukee, Wisconsin 53211, USA.

HYPSIBOAS ALBOPUNCTATUS (Spotted Treefrog). **PREDATION.** Anurans have behavioral traits that expose them to the risk of predation, and are preyed on by invertebrates, fishes, anurans, reptiles, and birds (Pombal Jr. 2007. Rev. Bras. Zool. 24[3]:841–843; Muniz et. al. 2008. Iheringia 98[2]:254–259; Ghizoni-Jr et. al. 2000. Melopsittacus 3[3]:137–139). However, predation is difficult to document in nature, but it is estimated that such events occur frequently (Pombal Jr. 2007, *op. cit.*).

Hypsiboas albopunctatus is a medium-sized hylid found in Brazil, Argentina, Uruguay, Bolivia, and Paraguay (Frost 2009. Amphibian Species of the World: an Online Reference.< http://research.amnh.org/herpetology/amphibia>. 10 Sept 2009), and is known to occur in Floresta Nacional (FLONA) of Silvânia (16.6588889°S, 48.6080556°W, 900 m elev.), state of Goiás, central Brazil. *Hypsiboas albopunctatus* are often observed in open areas and along streams. Herein, we record predation of an adult *H. albopunctatus* by the viper, *Bothrops moojeni* in the FLONA.

On 08 January 2009 at 2230 h, a juvenile *B. moojeni* was observed ingesting a *H. albopunctatus*. This observation occurred along a stream, where other anurans including *H. lundii*, *H. goianus*, and *Scinax centralis*, are found and could be potential prey of *B. moojeni*. This event was photographed and observation began when the snake had already captured the *H. albopunctatus*. Observations lasted ca. three minutes until the frog was fully ingested, and after this the *B. moojeni* remained still. In Atlantic rainforest**,** *B. jararaca* is a sit and wait predator, where the prey approaches the predator (Hartmann et. al. 2003. Phyllomedusa 2[1]:35–41). We suggest that the predation event reported herein may have occurred in a similar way.

The photographs were deposited at Laboratório de Comportamento Animal/DBG/ICB.

Submitted by **ALESSANDRO R. MORAIS, LUCIANA SIGNORELLI, RAÍSA VIEIRA,** and **ROGÉRIO P. BASTOS**, Laboratório de Herpetologia, Instituto de Ciências Biológicas, Universidade Federal de Goiás, Brazil (e-mail: alessandrogyn@hotmail.com).

ISCHNOCNEMA RAMAGII (Paraiba Robber Frog). **PREDATION.** Spiders are well known predators of small amphibians (Del-Grande and Moura 1997. Herpetol Rev. 28:147; Formanowicz et al. 1981. Herpetologica 37:125–129; Menin et al. 2005. Phyllomedusa 4[1]:39–47). *Ischnocnema ramagii* is typical of areas of the Atlantic forest in northeastern Brazil, occurring in the state of Paraíba to Bahia (Frost 2008. Amphibian Species of the World 5.2 – An Online Reference Amer. Mus. Nat. Hist.: http://research.amnh.org/herpetology/amphibia/index.php, accessed 12 May 2008). *Ischnocnema ramagii* lives in the sub-forest above the forest floor litter (Juncá 2006. Biota Neotrop. 6[2]:1–17).

Herein we report two events of predation on adult *I. ramagii* (21.1 and 19 mm SVL, Fig. 1) by the spiders *Ancylometes rufus* and *Ctenus rectifier* (Ctenidae). The observation occurred on 02 October 2008 at 1900 h and on 20 November 2008 at 1930 h in an area of Atlantic forest in the Parque Nacional Serra of Itabaiana (10.7488889°S, 37.3419444°W; SAD 69), Sergipe, Brazil. In Brazil, the spiders *Ancylometes* and *Ctenus* are known anuran predators (Bernarde et al. 1999. Biociências 7:199–203; Rodrigues et al. 2007. Herpetol. Rev. 38; Menin et al. 2005. Phyllomedusa 4:39–47; Serafin et al. 2007. Herpetol. Rev. 38:437, but these reports are from the northern and southeastern regions of Brazil; there are no reports from northeastern Brazil. Additionally, we are unaware of any reports documenting the

FIG. 1. The spider *Ancylometes rufus* preying on an adult *Ischnocnema ramagii*.

predation of *Ischnocnema ramagii* by spiders. The spiders were collected and deposited in the Coleção of Arachnids and Chilopoda, Instituto Butantan (IBSP122.178 and IBSP122.179) and the anurans in Coleção Herpetológica, Universidade Federal of Sergipe (CHUFS 00200, 00201).

We thank Antonio D. Brescovit (Laboratório of Aracnologia - Instituto Butantan) for identification of the spiders and Fábio Santos do Nascimento (Universidade Federal of Sergipe) and Thaís B. Guedes (LEEV - Instituto Butantan) for revision of the manuscript.

Submitted by **CRIZANTO BRITO DE-CARVALHO** (e-mail: crizantobrito@gmail.com), **EVELLYN BORGES DE FREITAS,** and **RAFAEL ALVES DOS SANTOS,** Núcleo de Pós-Graduação em Ecologia e Conservação - NPEC- Universidade Federal de Sergipe, CEP 49.000-000, São Cristovão, Aracaju, Sergipe, Brazil; and **FERNANDA BARROS GUEIROS, RÉGIS VINICIUS SOUZA SANTOS,** and **RENATO GOMES FARIA,** Laboratório de Herpetologia, Universidade Federal de Sergipe, CEP 49.000-000, São Cristovão, Aracaju, Sergipe, Brazil.

LEPTODACTYLUS SAVAGEI (Smoky Jungle Frog) **ANTIPREDATOR DEFENSE.** Amphibians possess a broad suite of chemical defenses to deter predators (Toledo and Jared 1995. Comp Biochem Physiol. 111A:1–29), and this can lead to an evolutionary arms race between predator and prey. Snakes are common predators of amphibians and many amphibians have evolved toxins that deter them (Williams et al. 2003. Herpetologica 59:155–163). *Leptodactylus savagei* (Heyer 2005. Arq. Zool. 37:269–348) is a large, robust frog with males reaching 177 mm and females reaching 185 mm SVL (Savage 2002. Amphibians and Reptiles of Costa Rica. A Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp). This species ranges from Honduras to central Colombia and is a common inhabitant of SW Costa Rica. It has been reported anecdotally that this species produces noxious compounds in its skin that may cause a skin rash, sneezing, and irritation of mucus membranes in humans (Savage 2002, *op. cit.*; Toledo et al. 2007. J. Zool. 271:170–177). These noxious skin compounds may have evolved to deter vertebrate predators, yet Roberts (1997. Herpetol. Rev. 28: 84–85.) reported predation of *L. pentadactylus* by the mustelid *Lutra longicaudus* in Brazil.

One of the more commonly encountered snakes in SW Costa Rica is the viper *Bothrops asper*, which can reach lengths of 2.3 m (Solórzano 2004. The Snakes of Costa Rica. INBio. 791 pp.). This snake is a generalist predator, and juveniles and subadults consume mostly frogs and lizards and broaden their diets to include birds and mammals when they become adults (Solórzano 2004, *op. cit.*). Solórzano (2004, *op. cit.*) reports that *B. asper* consumes members of Leptodactylidae, and there are no reports of *B. asper* having adverse reactions to noxious prey. Herein we report a predation attempt by *B. asper* (109 cm TL) on an adult *L. savagei* (101 mm male) where the snake experienced severe deleterious effects apparently from skin toxins of *L. savagei*.

Our observations occurred at a small stream at Tres Piedras, Puntarenas Province, Costa Rica (9.325°N, 83.8666667°W; 95 m elev.) on 24 July 2004. We first encountered the predation event at 2030 h, after the snake had struck the frog and began to consume it. We observed the snake for ca. 10 min. from a distance of 2 m in the streambed. During this time the snake was slowly ingesting the frog headfirst and had reached the frog's forelimbs when we left. The ingesting motions were extremely slow at this time, and we estimate that in 10 min. the snake had consumed ca. 0.5 cm of the frog. We marked the spot of the predation event along the stream and continued our survey. We returned to the location after 45 min. to find the frog dead and regurgitated on the sandy stream bank with two fang marks on its head. The snake was about 1 m downstream of the frog. The snake was lethargic and had difficulty moving when approached. When disturbed, the snake made no attempt to coil and exhibited no defensive actions. We gently turned the snake onto its back using a stick and the snake had difficultly righting itself and made no attempt to strike or escape. We observed the snake for 60 min. after finding it in this state and gently disturbed it every 15 min. to judge possible recovery. After 30 min. the snake still made no defensive or escape movements and when turned on its back it could no longer right itself. After 45 min. the snake began to show signs of recovery, slowly reacting to being touched. We slowly turned the snake on its back a third time and it was able to right itself, but was still moving very slowly. After 60 min. the snake appeared to become more aware and reacted with a quick jerk when touched, and eventually slithered slowly up the stream bank. However, the snake still did not appear to be acting normally at this point as most of its reactions were slow and its movements seemed disoriented. At ca. 105 min. after we discovered it attempting to prey on the *L. savagei*, the snake was finally moved out of the stream bank and it took cover under a log.

We infer that the sluggish behavior of the *B. asper* was due to toxic skin secretions from the *L. savagei* it was attempting to ingest. To our knowledge this is the first report of poisoning of a *B. asper* by *L. savagei*. Although the long-term effects of poisoning on this snake are unknown, it was totally incapacitated and incapable of moving or defending itself for ca. 45 minutes.

One of the skin compounds found in *L. pentadactylus*—sister species to *L. savagei*—is leptoxin, a novel, proteic toxin that is one of the most lethal protein toxins known (Limaverde et al. 2009. Toxicon 54:531–538). When ingested by laboratory rats, leptoxin induced cardiorespiratory collapse with abundant

FIG. 1. Adult *Bothrops asper* attempting to swallow an adult *Leptodactylus savagei* in SW Costa Rica. This photo was taken when the event was first observed and the snake was already lethargic. Soon after this photo the snake regurgitated the frog.

tracheal secretion followed by sudden death (Limaverde 2009, *op. cit.*). Leptoxin is not active orally at doses greater than 100 times higher than LD_{50} and therefore appears not to be a predator deterrent (Limaverde 2009, *op. cit.*). It is unclear if leptoxin played a role in poisoning the *B. asper*, but it is apparent that *L. savagei* possess a skin compound that can harm a predator. Even though the frog we observed died from the predation attempt, this snake may avoid *L. savagei* as a prey item in the future.

The fieldwork for this project was funded by Tropical Forestry Initiative through U.S. Forest Service Grant #03-DG-11132762-964. This project was written under funding from NSF DEB-0844624 to Steve Poe. We thank L. Gray, S. Poe, and E. Schaad for helpful comments on this paper.

LIMNONECTES KUHLII (Kuhl's Creek Frog). **DIET**. *Limnonectes kuhlii* is a medium-sized stocky anuran with a conspicuously broad head in males (Inger 2005. The Systematics and Zoogeography of the Amphibia of Borneo. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 402 pp.). This widespread species occurs in northeastern India, southern China, Hong Kong, Taiwan, Myanmar, Laos, Vietnam, Thailand, Peninsular Malaysia, Sumatra, Java, Borneo, and Sulawesi (AmphibiaWeb. http://amphibiaweb.org/ accessed 25 Sept 2009; Das 2007. A Pocket Guide: Amphibians and Reptiles of Borneo. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 200 pp.; Inger 2005, *op. cit.*). *Limnonectes kuhlii* dwells along the banks and in small to medium-sized streams with moderate to weak currents and rocky bottoms, as well as in silty rain puddles in primary and old secondary forests, and in the vicinity of human settlements from near sea level to 1750 m elev (Inger and Stuebing 2005. A Field Guide to the Frogs of Borneo. 2nd ed. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 201 pp.; Malkmus et al. 2002. Amphibians and Reptiles of Mount Kinabalu [North Borneo]. A.R.G. Gantner Verlag K.G. Ruggell. 424 pp.). To our knowledge, previous publications on the diet of *L. kuhlii* reported that the prey items are ants and insect larvae (Das 2007, *op. cit.*).

On 28 September 2008, between 1900 and 2200 h, an adult *L. kuhlii* (75 mm SVL, 41.3 g) was sampled at Sungai Lidan (5.9767°N, 116.52645°E; 1063 m elev.), Bundu Tuhan, Ranau District, West Coast Division, Sabah, Bornean Malaysia. Within 24 h, the anuran was identified, photographed, euthanized, and dissected, and the stomach contents were extracted. Upon examination, an adult *Tropidophorus beccarii* (71 mm SVL, partial tail length 54 mm) in the early stage of digestion was found in the stomach. The approximate prey/predator SVL ratio was 0.95. *Tropidophorus beccarii* (Scincidae) is a large and slender skink (< 99 mm SVL) endemic to Borneo, which prefers rocky streams in hilly forests up to 1000 m elev (Das 2007, *op. cit.*; Malkmus et al. 2002, *op. cit.*). The anuran (HEP00617) and skink (HEP00956) were deposited in BORNEENSIS, the Bornean reference collection of the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah.

Between June and December 2008, another 75 *L. kuhlii* were sampled and dissected as part of research on the biology of anurans at Bundu Tuhan. However, stomach content examination found no vertebrate prey items. Hence, this is the first and only record of *L. kuhlii* predating a reptile as well as a vertebrate.

We are grateful to Indraneil Das (Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak) for verification of the skink. We thank Agnes James Lintanga for field assistance and Paulus Abas for field transportation. Sampling was conducted under permission granted by Jawatankuasa Pemegang Amanah Hutan Simpanan dan Tanah Perumahan Bumiputera Kg. Bundu Tuhan, Ranau, to KBH. We also thank the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah for support.

LIMNONECTES KUHLII (Kuhl's Creek Frog). **MAXIMUM SIZE**. *Limnonectes kuhlii* is commonly found in or around water from in primary forests to the vicinity of human settlements up to 1750 m elev in northeastern India, southern China, Hong Kong, Taiwan, Myanmar, Laos, Vietnam, Thailand, Peninsular Malaysia, Sumatra, Java, Borneo, and Sulawesi (Das 2007. A Pocket Guide: Amphibians and Reptiles of Brunei. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 200 pp.; Inger and Tan 1996. The Natural History of Amphibians and Reptiles in Sabah. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 101 pp.; Inger and Stuebing 2005. A Field Guide to the Frogs of Borneo. 2nd ed. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 201 pp.; Malkmus et al. 2002. Amphibians and Reptiles of Mount Kinabalu [North Borneo]. A.R.G. Gantner Verlag K.G. Ruggell. 424 pp.). *Limnonectes kuhlii* is an anuran with a stocky body and short muscular limbs. The broad head is more prominent in males, enabling the males to grow larger than the females (Inger 2005. The Systematics and Zoogeography of the Amphibia of Borneo. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 402 pp.). Previous publications report the maximum size for *L. kuhlii* as 75 mm SVL (Das 2007, *op. cit.*; Inger 2005, *op. cit.*). Herein we report a new maximum size for the species.

On 17 Aug 2009, between 1900 and 2200 h, an adult *L. kuhlii* was sampled at Sungai Kepungit (6°N, 116.5439°E; 1394 m elev.), Bundu Tuhan, Ranau District, West Coast Division, Sabah, Bornean Malaysia. Air temperature was 18.6°C, and relative humidity was 84%. The specimen was 88 mm SVL, mass 61.7 g; measurements were taken with a standard metric tape and an electronic balance. The presence of a pair of conspicuous tooth-like projections on the lower jaw, and large size suggest that the anuran was male. The specimen (HEP00959) was deposited in BORNEENSIS, the Bornean reference collection of the Institute

for Tropical Biology and Conservation, Universiti Malaysia Sabah.

On the same night, 7 other *L. kuhlii* were sampled along the same river (range 27–81 mm SVL, mass range 1.7–61.6 g). Two specimens were larger than 75 mm SVL (HEP00960, 81 mm SVL, mass 61.6 g; and HEP00963, 77 mm SVL, mass 39.5 g).

We thank Agnes James Lintanga for field assistance and Applinious Sami for field transportation. Sampling was conducted under the auspices of Jawatankuasa Pemegang Amanah Hutan Simpanan dan Tanah Perumahan Bumiputera Kg. Bundu Tuhan, Ranau. We also thank the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah for support.

LITHOBATES CATESBEIANUS (American Bullfrog). **DIET**. *Lithobates catesbeianus* has been introduced globally. In Argentina, the species has been introduced in several provinces including San Juan (Sanabria et al. 2005. Multequina 14:65–68), Misiones (Pereyra et al. 2006. Cuad. Herpetol. 20:37–40), Buenos Aires (Barrasso et al. 2009. S. Amer. J. Herpetol 4:69–75), Córdoba (Akmentins et al. 2009. Cuad. Herpetol. 23:25–32), and Salta (Akmentins and Cardozo 2009. Biol Invasions DOI 10.1007/s10530-009-9515-3). These introductions have had negative impacts on the native fauna.

During March 2004, in the Calingasta department (coordenadas), San Juan Province, we captured 18 *L. catesbeianus* (145 ± 6.5 mm SVL). The diet consisted of ten prey categories, which were dominated by decapods. Table 1 provides a summary of these data.

We thank V. Videla and S. Segovia for help with field work.

TABLE 1. Stomach contents of the American Bullfrog, *Lithobates catesbeianus*, from San Juan Province, Argentina. LITORIA NANNOTIS (Australian Waterfall Frog). **FOOT FLAGGING.** Visual displays, including those involving movements of the feet, may act as a substitute for vocal communication in streamside environments where noise may interfere with detection of vocal signals (Heyer et al. 1990. Arq. Zool. 31:231–410). Foot flagging behavior by male *Litoria nannotis* has only been observed in the presence of conspecific males, and the display was presumed to be related to male-male aggression (Richards and James 1992. Mem. Queensland Mus. 32:302). In this note we describe, for the first time, foot flagging by a male *L. nannotis* in the presence of a female.

We observed the courtship at 22:00 h AEST 2 Sept 2009 on Cloudy Creek (18.9926167°S; 146.2103833°E; ca. 530 m elev.) in north Queensland, Australia. A male and female *L. nannotis* were observed on the vertical face of a granite boulder (ca. 0.6 m in diameter) near a small waterfall. The rock surface was barely wet, only just within reach of the splash zone. The pair were separated by a distance of ca. 30 cm; the female facing away from the male. The male was heard to call (a low growl) seven times at intervals of 3–5 minutes. When lit with shielded light, the male was seen to foot flag while calling; extending the left rear leg perpendicular to the body and rapidly vibrating the foot on a vertical plane with toes outstretched before returning the leg to the side of the body. The right leg was not involved. The female did not display any responses to the male, and did not move during our 45 minutes of observations. Although no other males were observed nearby, it is unknown if the intent of the foot flagging was to attract the female's attention, or discourage potential male rivals. We did not follow the behavior of the pair longer due to potential disturbance, as the male would cease foot flagging and calling with extended exposure to artificial light.

PHILLOTT,** School of Public Health, Tropical Medicine and Rehabilitation Sciences, James Cook University, Townsville Queensland 4811, Australia (e-mail: andrea.phillott@jcu.edu.au); and **SARA C. BELL,** School of Tropical and Marine Biology, James Cook University, Townsville Queensland 4811, Australia (e-mail: sara.bell@jcu.edu.au).

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). **PREY**. *Osteopilus septentrionalis* is native to Cuba, Cayman Islands, and Bahamas (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida. 155 pp.), and has been introduced into five states in the United States, but is established only in Florida (Barbour 1931. Copeia 1931:140; Crother 2008. Scientific and Standard English Names of Amphibians and Reptiles of North America. SSAR Herpetol. Circ. 37. 84 pp.). In Florida, *O. septentrionalis* is known to prey primarily on roaches (Dictyoptera), but has also been documented consuming lizards (anoles and geckos), frogs (including its own

FIG. 1. Non-native Cuban Treefrog (*Osteopilus septentrionalis*) preying upon native Ring-necked Snake (*Diadophis punctatus*).

species) (Meshaka et al. 2004, *op. cit.*), and the Florida Brown Snake (*Storeria victa*) (Maskell et al. 2003. Herpetol. Rev. 34:137). Herein, we report *O. septentrionalis* preying upon a native Ring-necked Snake (*Diadophis punctatus*) in Florida.

In Sept 2008 at 2100 h, an *O. septentrionalis* (ca. 6.3 cm SVL) was observed on SE Island Way, 0.08 km NE Loxahatchee River Road, Jupiter, Martin County (26.973996°N, 80.137637°W; WGS84, elev. <1 m) on a sidewalk holding a *Diadophis punctatus* (ca. 15 cm SVL) in its mouth. After being photographed (photographic voucher UF 154586), the frog continued to hold onto the snake without ingesting it entirely for more than 40 min, at which time the frog was left alone. This is the second record of this nonindigenous frog preying upon a native snake in Florida.

We thank Susan Speaks McGirt for use of this information and photographic voucher for documentation.

HALVORSEN**, The Palm Beach Zoo, 1301 Summit Blvd, West Palm Beach, Florida 33460, USA.

PHYSALAEMUS SPINIGER (Iguape Dwarf Frog). **PREDATION**. Anuran eggs, tadpoles, and post-metamorphic individuals are known to be preyed upon by vertebrates, invertebrates, and even carnivorous plants (Toledo et al. 2007. J. Zool. 271:170–177). Herein we here report dipteran maggot predation of *Physalaemus spiniger* eggs in a foam nest and spider (Theraphosidae) predation of an adult male. *Phylsalaemus spiniger* is a small frog (mean SVL males 18.8 mm; mean SVL females 21.1 mm) (Haddad and Pombal Jr. 1998. J. Herpetol. 32:557–565) that calls on the forest floor near temporary ponds. The eggs are laid in a foam nest that is deposited on the water surface near the edges of ponds, on the humid leaf litter near ponds, or in the axils of terrestrial bromeliads (Haddad and Pombal 2008, *op. cit.*). *Physalaemus spiniger* is known from the states of Paraná (Guaraqueçaba) and São Paulo (Ilha do Cardoso, Cananéia, Estação Ecológica da Juréia, Iguape, Caverna do Diabo, Iporanga, Jacupiranga), southern and southeastern Brazil

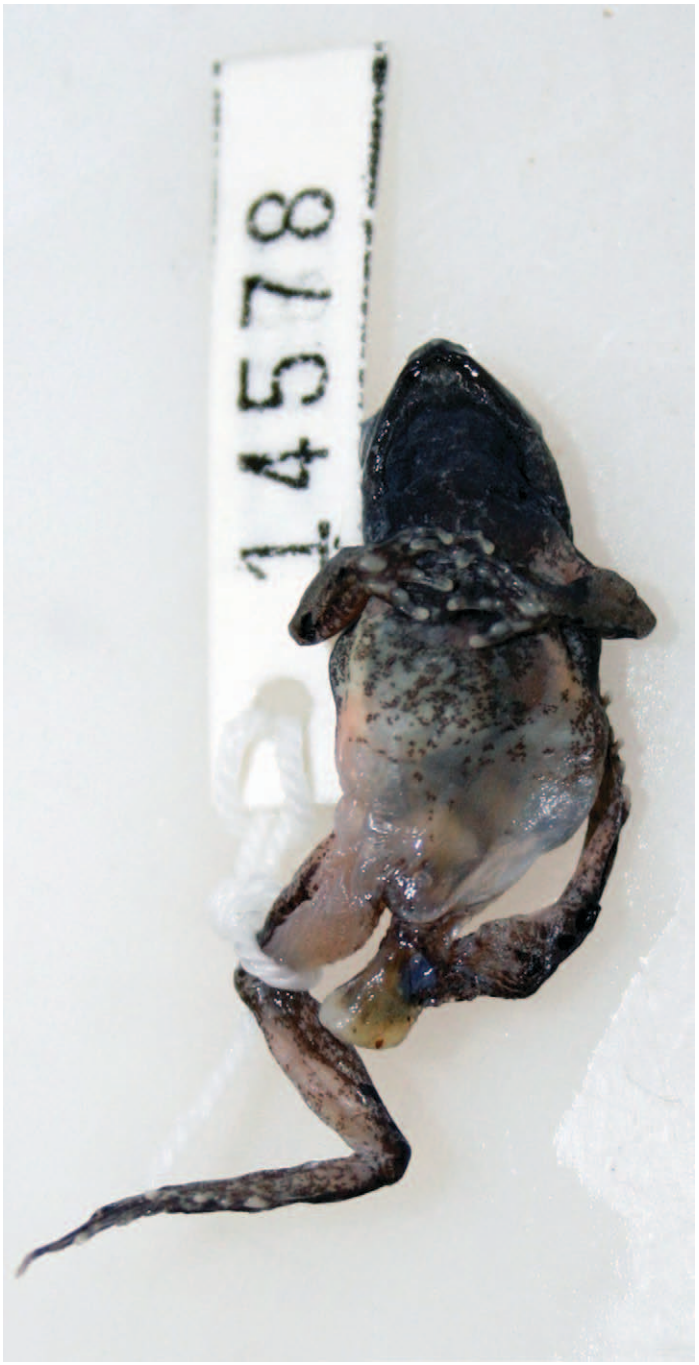

FIG. 1. *Physalaemus spiniger* preyed upon by a spider (Theraphosidae). The partially digested left leg is indicated by an arrow.

(Haddad and Pombal 2008, *op. cit.*). The risk of predation by invertebrates is greater during the breeding season (Toledo 2005. Herpetol. Rev. 36:395–400). Spiders are the most important invertebrate predator of post-metamorphic anurans (Toledo et al. 2007, *op. cit.*), and dipteran maggots are common predators of eggs and embryos (Menin and Giaretta 2003. J. Zool. 261:239–243). Reports of predation by invertebrates upon *Physalaemus* spp. have been published (Brasileiro et al. 2003. Herpetol. Rev. 34:137; Toledo 2003, *op. cit.*; Toledo 2005, *op. cit.*), and there is a report of spider predation (Lycosidae) upon *P. spiniger* (Toledo et al. 2007, *op. cit.*). On 27 October 2008 we found a *P. spiniger* foam nest with dipteran maggots that were feeding on the eggs. The following night we observed an adult male *P.*

spiniger (SVL 18.5 mm) being preyed upon by a juvenile spider (Theraphosidae; TL 19.5 mm). The *P. spiniger* was calling on the forest floor in Reserva Natural Salto Morato, Guaraqueçaba, Paraná, Southern Brazil (25.186643°S, 48.254730°W) at the edge of a temporary pond when it was captured by its left leg by the spider. Both individuals were captured and deposited in the Museu de Zoologia "Prof. Dr. Adão José Cardoso," at Unicamp, Campinas, Brazil (ZUEC 14578). After collecting the animals, the spider released the now paralyzed anuran, which died three hours after the observation with its left leg partially digested (Fig. 1). The size relationship observed in this predation event is consistent with data presented by Toledo et al. (2007, *op. cit.*) where solitary, venomous, and invertebrate predators generally eat prey that are a little shorter or equal to their own size.

We acknowledge FAPESP and CAPES for grants and scholarships.

PSEUDIS MINUTA (Lesser Swimming Frog). **CANNIBALISM.** Reports of cannibalism between adult anurans are scarce. Few reports have been published but include the ranids *Lithobates catesbeianus* (Stuart and Painter 1993. Herpetol. Rev. 24:103), *Rana cascadae* (Rombough et al. 2003. Herpetol. Rev. 34:138), and *R. luteiventris* (Pilliod 1999. Herpetol. Rev. 30:93), and the leptodactylid *Leptodactylus ocellatus* (Kokubum and Rodrigues 2005. Herpetol. Rev. 36:303). The paucity of reports suggests this interaction is uncommon among adult anurans (Toledo et al. 2007. J. Zool. 271:170–177), although it is well documented that tadpoles or adults eat conspecific tadpoles or eggs (Bragg 1946. Herpetologica 3:89–97; Caldwell and Araujo 2006. Biotropica 30:92–103; Crump 1990. Copeia 560–564; Drewes and Altig 1996. Tropical Zool. 9:333–347; Summers 1999. Oecologia 119:557–564;). Herein we report cannibalism in an adult male *Pseudis minuta.*

The specimens were collected in a temporary pond in the Department of Tacuarembó, Uruguay (32.4118611°S, 55.5369167°W; WGS84, 99 m elev.), on 8 Aug 2009. Air temperature was 10.3ºC; water temperature was 11.3ºC. The predator was an adult female (44.44 mm SVL, 11.85 g, mandibular width 15.3 mm), whereas the prey was a male (23.17 mm SVL, 1.39 g, mandibular width 9.32 mm) (Fig. 1). The male (dead when was recovered), was catalogued into the Vertebrates

FIG. 1. Female *Pseudis minuta* eating conspecific male (ZVCB 19898).

Collection of the Faculty of Sciences (ZVCB 19898).The marked female was not collected as this population is being monitored in a long-term mark-recapture study.

RANA LUCTUOSA (Mahogany Frog). **ALTITUDE AND MAXIMUM SIZE**. *Rana luctuosa* is an anuran with a distinctive coloration of rich reddish chocolate dorsum of the head and body separated by two thin dorsolateral whitish stripes from its greyish black sides of head and body (Inger and Stuebing 2005. A Field Guide to the Frogs of Borneo. 2nd ed. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 201 pp.). The species occurs in Central Peninsular Thailand, Peninsular Malaysia, Sumatra, and Borneo (western Sabah, and Sarawak) (Frost 2009. Amphibian Species of the World: an Online Reference, ver. 5.3 [12 Feb 2009]. http://research.amnh.org/herpetology/amphibia/. American Museum of Natural History, accessed on 14 Oct 2009; Inger 2005. The Systematics and Zoogeography of the Amphibia of Borneo. Natural History Publications [Borneo] Sdn. Bhd. Kota Kinabalu. 402 pp.; van Dijk et al. 2004. *In* IUCN 2009. IUCN Red List of Threatened Species. Version 2009. <www. iucnredlist.org>, accessed on 14 Oct 2009). Previous publications reported the altitudinal range for the species to be 100–1400 m (Malkmus et al. 2002. Amphibians and Reptiles of Mount Kinabalu [North Borneo]. A.R.G. Gantner Verlag K.G. Ruggell. 424 pp.; van Dijk et al. 2004, *op. cit.*), and the maximum size to be 60 mm SVL (Inger and Stuebing 2005, *op. cit.*; Malkmus et al. 2002, *op. cit.*).

On 13 Dec 2008, between 1900 and 2200 h, an adult *R. luctuosa* was collected at an artificial pond within the compound of Haleluyah Retreat Centre (6°N, 116.536° E; 1500 m elev.), Bundu

Tuhan, Ranau District, West Coast Division, Sabah, Bornean Malaysia. Air temperature was 16°C, and relative humidity was 89.1%. Due to proximity to protected areas (Kinabalu National Park on the east, and Tenompok Forest Reserve on the west), and the mostly retained surrounding vegetation, Haleluyah Retreat Centre houses other forest and forest edge species of anurans: *Philautus petersi*, *Megophrys baluensis*, and *Limnonectes kuhlii*, in addition to the human commensal species *Polypedates leucomystax*. The locality represents an altitude record for *R. luctuosa*, as well as suggests an extension of habitat previously expected to be forests for the species.

The specimen was 68 mm SVL, mass 26.1 g; measurements were taken with a standard metric tape and an electronic balance. The specimen (HEP00951) was deposited in BORNEENSIS, the Bornean reference collection of the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah. The specimen represents a new maximum size for *R. luctuosa*. On the same night, two additional *R. luctuosa* were obtained at Haleluyah Retreat Centre. Both were larger than the previously known maximum size for the species (HEP00950, 64 mm SVL, mass 19.7 g, and HEP00952, 63 mm SVL, mass 22.1 g).

We thank Haleluyah Retreat Centre for permission to collect specimens, and the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah for support.

RHACOPHORUS FEAE (Thao Whipping Frog). **DEFENSIVE BEHAVIOR.** A wide variety of defensive behavior aimed at predation avoidance has been reported in amphibians. During surveys in Kon Tum Province, Vietnam, we captured a single specimen of the large rhacophorid frog, *Rhacophorus feae*. When grasped by the hand, on several occasions, the individual raised its forearms to the head, positioning its thumb below the eye and the remaining fingers splayed above the eye. The pale pink ventral surfaces of the fingers contrast with the dark green head and dorsal surface of the frog. The eyes were always open during this behavior, with the nictating membrane at most partially covering the eye (Fig. 1). No sounds or obvious smell was emitted by the frog during this behavior. Similar behavior has been reported in a taxonomically and geographically diverse group of frogs; the North American ranid frogs *Rana aurora draytonii* (Wilkinson 2006. Herpetol. Rev. 37:207–208) and *R. capito* (Means 2004. Herpetol. Rev. 35:163–164), the South American hylids *Hyla calcarata* and *H. fasciata* (Angulo and Funk 2006. Herpetol. Rev. 37:203–204), the Madagascan mantellid frog *Boophis albilabris* (Andreone 2002. Herpetol. Rev. 33:299–300), and the Southeast Asian rhacophorid *Nyctixalus pictus* (Das et al. 2004. Herpetol. Rev. 35:363–374). Previous suggestions as to the adaptive significance of the behavior include disrupting the search image of predators by changing the outline of the head (Channing and Howell 2003. Herpetol. Rev. 34:52), "increasing" head size, or making ingestion difficult (Angulo and Funk 2006, *op. cit.*).

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Defensive display of *Rhacophorus feae* from Kon Tum Province, Vietnam.

The distinctly contrasting color of the ventral surface of *R. feae* displayed during this behavior might also act aposematically.

RHINELLA PYGMAEA (Rio Parahyba Toad). **ECTOPARASITISM.** *Rhinella pygmaea* is a bufonid endemic to the Atlantic Rainforest biome, occurring in restingas (coastal sand-dune shrublands) of Rio de Janeiro State, Brazil (Carvalho-e-Silva et al. 2000. *In* Esteves and Lacerda [eds.]. Ecologia de Restingas e Lagoas Costeiras, pp. 89–97; Rocha et al. 2005. Braz. J. Biol. 65:159–168) and in a disturbed forest fragment of Mimoso do Sul municipality in Espírito Santo state (Silva et al. 2007. Herpetol. Rev. 38:97). It is threatened by habitat loss, but its conservation status is reported as Least Concern (IUCN 2008. The IUCN Red List of Threatened Species. <http://www.iucnredlist.org/details/54740>. 04 Mar 2009). Here we report observations of parasitism on *Rhinella pygmaea* by a tick of the genus *Amblyomma*.

On 9 Feb 2009, during fieldwork at the Grussaí restinga, municipality of São João da Barra, in northern Rio de Janeiro State (21.9813889°S, 41.0608333°W), a subadult *Rhinella pygmaea* (ca. 30 mm SVL) was observed parasitized by a tick of the genus *Amblyomma*. The female tick (length 10 mm x width 5 mm) was attached on the posterior part of the toad's dorsum (Fig. 1). The tick was collected and preserved in 70% ETOH. In the laboratory, the tick was identified as *A. rotundatum* using the key of Aragão and Fonseca (1961. Mem. Inst. Oswaldo Cruz 59:115–129). This is one of the few tick species that reproduce by parthenogenesis (Aragão 1912. Mem. Inst. Oswaldo Cruz 4:96–118), and also the one that most frequently feeds on amphibians (Hanson et al. 2007. J. Med. Entomol. 44[1]:155–157). *Amblyomma rotundatum* previously has been reported to feed on other species of *Rhinella*

FIG. 1. Subadult *Rhinella pygmaea* (about 30 mm SVL) parasitized by the tick, *Amblyomma rotundatum* (length 10 mm x width 5 mm).

(Lampo and Bayliss 1996. Parasitology 113:199–206; Luque et al. 2005. Acta Parasitol. 50:215–220; Smith et al. 2008. J. Parasitol. 94:560–562). This ixodid tick is native to Central and South America but is also found in North America (Florida, USA) where it was probably introduced with the Giant Toad, *Rhinella marina* (Oliver et al. 1993. J. Parasitol. 79:786–790). This is the first report of parasitism by *A. rotundatum* on *Rhinella pygmaea*.

We thank Mara Cíntia Kiefer and Davor Vrcibradic for their critical reading of the manuscript.

SCINAX X-SIGNATUS **(**Venezuela Snouted Treefrog). **PREDATION**. Anurans are often predated by invertebrates, including spiders (Barbo et al. 2009. Herpetol. Notes 2:99–100; Menin et al. 2005. Phyllomedusa 4:39–47), chilopods (Forti et al. 2007. Braz. J. Biol. 67:583–584), and hemipterans (Pombal 2007. Rev. Brasil. Zool. 24:841–843). Predation is an important factor regulating anuran populations (Duellman and Trueb 1994. Biology of Amphibians. Johns Hopkins, New York. 670 pp.).

Scinax x-signatus is a species typical of non-forest habitats and occurs in northern Colombia and Venezuela to Suriname, and in eastern, southern, and southeastern Brazil (Frost 2009. Amphibians Species of the World 5.2 – an online reference. Am. Mus. Nat. Hist.: http://research.amnh.org/herpetology/amphibia/references; accessed 08 Sept 2009). In northeastern Brazil, *S. x-signatus* has been observed active near the margins of ponds

FIG. 1. A nymph of the Giant Water Bug, Belostomatidae, preying on an adult Venezuela Snouted Treefrog, *Scinax x-signatus*.

under vegetation (Vieira et al. 2007. Oecol. Bras. 11:383–396) as well as in this study area.

Herein we report predation of an adult *S. x-signatus* (39.5 mm SVL, Fig. 1) by a nymph Giant Water Bug (Belostomatidae). The observation occurred on 04 Aug 2009 at 2200 h in a temporary pond in Poço Redondo city, (9.6869444°S, 37.6813889°W; SAD-69), Sergipe, Brazil. Belostomatids are found in ponds and lakes and feed on other insects, tadpoles, and small fishes. (Borror et al. 1989. Introduction to the Study of Insects. 6th ed., Saunders College Publishing. 875 pp.). Predation on frogs involving belostomatids have been reported from southeast Brazil (Pombal 2007. Rev. Brasil. Zool. 24:841–843; Toledo 2003. Phyllomedusa 2:105–108), although there are no reports from the Caatinga areas. The Giant Water Bug was collected and is deposited in Coleção do Laboratório de Entomologia (ENT100) and the *S. x-signatus* in Coleção Herpetológica da Universidade Federal de Sergipe (C360).

We thank Leandro de Sousa Souto, Yana Teixeira dos Reis, and José Oliveira Dantas (Laboratório de Entomologia) for identification of the belostomatid, Luciano de Araujo Pereira for the photograph, and Bruno Durte da Silva (Universidade Federal of Sergipe) for help in translation of this manuscript.

TRACHYCEPHALUS JORDANI (Jordan's Casque-Headed Treefrog). **PREDATION.** *Trachycephalus jordani* is a moderately large hylid frog native to the Pacific lowlands of Colombia, Ecuador, and Peru. We report an instance of *T. jordani* feeding on the hylid frog, *Hypsiboas pellucens* (Palmar Treefrog), which is sympatric with *T. jordani* in the Pacific lowlands of Colombia

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Jordan's Casque-headed Treefrog (*Trachycephalus jordani*) eating a Palmar Treefrog (*Hypsiboas pellucens*) in Pichincha, Ecuador.

and Ecuador (Icochea et al. 2004. *In* IUCN 2009. IUCN Red List of Threatened Species. Version 2009.2. <www.iucnredlist.org>. Downloaded 12 Nov 2009.).

At 2135 h on 14 May 2007, in Bosque Protector La Perla, 1.54 km SSW of La Concordia (0.013113°S, 79.3879908°W, elev. 252 m) in Pichincha Province, Ecuador, we found a *T. jordani* of unknown gender measuring 38.2 mm SVL. Protruding from the *T. jordani*'s mouth were the hind feet of a live *H. pellucens* of unknown gender measuring 20.75 mm SVL (Fig. 1).

Documented cases of anurans in the diet of other frogs have thus far been limited to: 1) cannibalism of eggs and other larvae by tadpoles, usually of tree cavity or bromeliad-nesting species (Crump 1983. Am. Nat. 181:281–289); 2) a few cases of conspecific cannibalism of adults; and 3) opportunistic predation of non-conspecifics by such 'convenience predators' (Toledo et al. 2007. J. Zool. 217:170–177). To our knowledge only two observations of a hylid frog reported to consume other treefrogs have been reported (*Hypsiboas faber*, Solé et al. 2004. J. Nat. Hist. 41:2757–2763; *Osteopilus septentrionalis*, Wyatt and Forys 2004. Southeast. Nat. 3:695–700).

GYMNOPHIONA — CAECILIANS

***DERMOPHIS* SP**. (NCN). **PREDATION**. *Dermophis* is a caecilian genus with a Mesoamerican distribution. It is known from lowland to mid elevation forests ranging between Mexico and Colombia (Savage 2002. The Amphibians and Reptiles of Costa Rica. Chicago Univ. Press). As with most caecilians, the biology of this genus is largely unknown. There are several reports of caecilians as prey of snakes in Africa (Gower et al. 2004. Afr. J. Ecol. 42:83–87), Asia (Kupfer et al. 2003. Amphibia-Reptilia 24:212–215) and the Americas (Savage 2002, *op. cit.*; Schmidt 1932. Copeia 1932:6–9), however there are few observations of the predator-prey behavior in the field (Kupfer et al. 2003, *op. cit.*).

On 8 July 09 at 1000 h, at Piedras Blancas National Park near Esquinas Lodge in La Gamba (Golfito, Puntarenas, Costa Rica) the author observed the predation of *Dermophis* sp. by the elapid snake *Micrurus alleni*. Both animals were at the edge of a forest trail. The substrate was composed of red clay, crushed stone (placed there artificially), and leaf litter, with some tree roots on the surface. In general the soil, roots, and litter were moist to wet, and the closed canopy didn't allow much light to reach the ground. A small creek was located ca. 100 m away from the observation. At the moment of the sighting the weather was cloudy, even though from dawn to 0930 h of the same day it was clear and the previous day it had rained in the afternoon. Upon my arrival I observed that the snake had already captured the caecilian, holding the anterior portion of the amphibian (part of the cervical area) in its mouth (Fig. 1). Even though neither animal was measured, the *Dermophis* was longer but thinner than its predator. The complete ingestion of the caecilian by the snake was not observed, but during the course of the observation (ca. 15 minutes) the caecilian remained alive and the snake did not release it, keeping its mouth in place, even after the snake noticed the presence of humans ca. 1.5–2 m away. The anterior portion of the caecilian did not move as much as its posterior portion, which writhed slowly and rather inactively. About 3 min. after the initial observation, the snake started to move, wriggling backwards, pulling the caecilian across the trail. This behavior was repeated 3 times until I left. Between each pulling activity the snake remained largely still for periods ranging between 3 and 7 minutes.

It was suggested that the species of *Dermophis* observed was *D. parviceps* according to the characteristics of the head, and the color and proportions of the body. However this specimen was unusually long, so the identification to species level has not been confirmed.

Thanks to A. Ruiz for the photograph, E. Boza and A. Solano for their suggestions, M. Wake, G. Chaves, and A. García for their help with the identification of the specimen, and P. Hanson for proofreading the manuscript.

TESTUDINES — TURTLES

APALONE SPINIFERA (Spiny Softshell Turtle). **MAXIMUM CLUTCH SIZE.** Maximum clutch size for *Apalone spinfera* is currently recognized as 39 eggs (Ernst and Lovich 2009. Turtles of the United States and Canada. Second Edition. Johns Hopkins Univ. Press, Baltimore, Maryland. 828 pp.). Here, I report an observation of a single *A. spinifera* nest from Butler Co., Iowa, USA that contained 42 eggs, apparently a record clutch size for this species, as well as the largest known clutch for any of the

three North American *Apalone* species (*A. ferox*, *A. mutica*, and *A. spinifera*).

On 17 June 2009 at 1930 h I observed an adult female *A. spinifera* constructing a nest on the bank of the West Fork Cedar River. The eggs were deposited in open sand, approximately 12 m from water, at a site that *A. spinifera*, *A. mutica* and *Chelydra serpentina* frequently use for nesting. The nesting female was left undisturbed and the nest was excavated shortly after completion. Total clutch wet mass was 399.71 g; mean egg mass was 9.52 g (SD = 0.63 g, range = 8.18–10.74 g), and mean egg diameter was 25.61 mm (SD = 0.70 mm, range = 24.30–27.17 mm). Eggs in this clutch (N = 42) were more numerous and significantly ($p<0.0005$) lighter and smaller than eggs from 14 other *A. spinifera* nests from this site. Mean clutch size of 14 *A. spinifera* nests (249 eggs total) at this site was 19.26 (SD = 5.19; range = 11–27); mean total clutch wet mass was 180.10 g (SD = 59.89 g, range = 94.18–294.20 g), mean egg wet mass was 10.25 g (SD = 1.07 g, range = 7.95–12.82 g), and mean egg diameter was 26.56 mm (SD = 1.09 mm, range = 22.97–29.39 mm). Total wet mass of this record clutch was ≈120% heavier than the mean wet mass of nests recorded from this site. This clutch was collected and incubated in the laboratory; 39 of the 42 eggs proved fertile, but unfortunately a storm-caused power outage and a subsequent spike in incubator temperature resulted in embryonic death in these eggs.

Clutch size varies greatly in all three *Apalone* spp.; nests may contain as few as 1–3 eggs and maximum clutch size is 40 for *A. ferox* and 33 for *A. mutica*. *Apalone spinifera* may produce two, and possibly even three, clutches per nesting season (Ernst and Lovich, *op. cit.*). Since 2003, *Apalone spinifera* nesting dates have ranged from May 30–July 29 at this site, with early clutches often laid from late-May to mid-June and second clutches laid throughout July. In 2009, following a harsh winter and an unusually cold, wet spring, turtle nesting at this site was delayed by several weeks; consequently, this record clutch may have represented a delayed first clutch and possibly included eggs that would, in a more normal year, have been deposited in a second clutch.

I thank Rick Fisher for access to the nesting site. This work was conducted under Iowa DNR Scientific Collecting permit SC-648.

Submitted by **JEFFREY W. TAMPLIN**, Department of Biology, University of Northern Iowa, 1227 W 27th Street, Cedar Falls, Iowa 50614 USA; e-mail: jeff.tamplin@uni.edu.

CHELYDRA SERPENTINA (Common Snapping Turtle). **DIET, FRUGIVORY.** On 18 June 2008 a DOR adult *C. serpentina* was found on the shoulder of Interstate 85 in Macon Co Alabama (32.4519833°N, 85.7396667°W; WGS84) with an estimated carapace length of ~25 cm and a 6 cm skull width. Though the carapace was damaged and the flesh putrefied, it was collected for deposition as an osteological specimen in the AU Natural History Museum collection (AUM Osteo 4655). The entire specimen was wrapped securely in window screen (to prevent loss of small bones) and placed under half a 208-liter plastic drum weighted with cinderblocks to continue decomposition. After several months the specimen was removed and the bones picked from the remaining detritus. During this process, several small, hard, round objects were encountered in the abdominal region and at first were thought to be disarticulated wrist or ankle bones. Upon closer examination, they were identified as the pits of the Common Black Cherry (*Prunus serotina*). All of the bones and materials previously picked through were carefully re-examined and a total of 14 pits were recovered from the carcass as well as a cheliped from a crayfish (*Procambarus* sp.) and two additional crayfish exoskeleton fragments.

It seems highly unlikely that a small rodent would have cached the seeds in the carcass as it was under a weighted barrel and tightly wrapped in mesh. In addition, there are no *P. serotina* trees growing in the vicinity of the skeletonizing site. Furthermore, the number of seeds found within the carcass implies that they were ingested deliberately.

Though *C. serpentina* are primarily carnivores, they have been documented to consume a variety of plant material (Ernst and Lovich. 2009. Turtles of the United States and Canada. Johns Hopkins Univ. Press. 840 pp.; Steyermark et al. [eds]. 2008. Biology of the Snapping Turtle. Johns Hopkins Univ. Press. 240 pp.). More recently, a report by Aird (2008. Bull. Chicago Herpetol. Soc. 43[12]:189–195) contains an amusing account of terrestrial frugivory by this species. This observation provides additional support for occasional frugivory in this turtle and is the first record of *P. serotina* being consumed by *C. serpentina*. Because the seeds noted here were intact, there is the potential for seed dispersal by this species, however neither seed viability nor germination were tested.

Thanks to S. Graham for reviewing this note.

DEIROCHELYS RETICULARIA (Chicken Turtle). **COURTSHIP BEHAVIOR**. *Deirochelys reticularia* is a semi-aquatic species that inhabits the southeastern United States. Extant *Deirochelys* is a monotypic genus in the family Emydidae, subfamily Deirochelyinae which also includes *Chrysemys* (Painted Turtles), *Graptemys* (Map Turtles), *Malaclemys* (Diamond-backed Terrapins), *Pseudemys* (Cooters), and *Trachemys* (Sliders). Courtship behavior referred to as "titillation" has been considered a unique characteristic of the Deirochelyinae (Seidel and Fritz. 1997. Herpetol. Rev. 28:70–72). Males are typically smaller than females and have elongate foreclaws. During titillation courtship, the male approaches the female in water and extends his forelegs, while rapidly vibrating the claws against or near the female's ocular region. It has been inferred that this behavior is represented in all genera of the subfamily (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed., Johns Hopkins Press, Baltimore; Fritz 1991. Salamandra 27:129–142; Seidel and Fritz 1997, *op. cit.*).

Courtship in *Deirochelys* has not been well documented and to my knowledge has not been reported in nature. Thus all observations are based on captive individuals. Krefft's publication in German (1951. Aquar. -u. Terrar. -Z., Stuttgart, 4:157–160) apparently was the first description of *D. reticularia* courtship behavior. This paper has been cited several times as evidence for titillation-like courtship in *Deirochelys* (Ernst and Lovich 2009, *op. cit.*;

Fritz 1991, *op. cit.*; Seidel and Fritz 1997, *op. cit.*). However, re-evaluation of Krefft's report does not substantiate vibration of the male's foreclaws around the female's ocular region. Uwe Fritz (Museum of Zoology, Dresden, Germany) recently provided me with the following exact translation of Krefft's (1951, *op. cit.*) pertinent statements: " [male *Deirochelys*…approaching the other turtle from the front]…whereby the forelegs were widely spread, sometimes performing shaking/ vibrating movements. These movements were much slower and with a distinctly more divergent angle than in *Pseudemys* [= *Trachemys scripta*]." Fritz stated (pers. comm.) that Krefft's description can be literally interpreted as if only the arms are performing the movements, confirming that Krefft did not specifically mention involvement of the foreclaws. A more recent description of courtship activity in Chicken Turtles is presented by Ewert et al. (2006. *In* Meylan [ed.], Chelonian Res. Monogr. [3]:249–259). These authors stated that: "In several cases the male swam obliquely, with a forelimb leading, as he approached the female from the front. During the approach, the male fluttered both forelimbs in a series of many (often > 10) short, rapid swimming strokes, with his head partly extended and with his gaze from one eye, seemingly focused on the female's head." Dale Jackson (Florida Natural Areas Inventory, Tallahassee) added (pers. comm.) that Ewert (now deceased) referred to the male's activity as "flopping his front legs around (sort of waving)."

Another recent account comes from Rudolf Wicker (Frankfurt Zoological Garden, Germany), who informed me (pers. comm.) that he and his zoo staff "…regularly observe courtship behavior in *Deirochelys*, but never observed anything like titillation, but waving with one arm alternately." As a final note, I observed attempted mating of a captive pair of Chicken Turtles. In this incident the young male did not display courtship but pursued the female several times from behind, nudging her with his snout, then extending his tail to achieve cloacal apposition.

When all evidence of courtship is considered, it appears doubtful that *D. reticularia* employs actual titillation behavior. Males do not have especially long foreclaws and do not vibrate their digits, as seen in other genera of the subfamily. Nevertheless, if the waving or vibrating of the male Chicken Turtle's forelegs is homologous with titillation, it may have evolutionary significance. Modern phylogenetic theories (based on morphology and nucleotide sequence data) indicate that *Deirochelys* is the sister group (basally divergent) to a complementary clade of *Chrysemys*, *Pseudemys*, *Trachemys*, *Malaclemys*, and *Graptemys* (Bickham et al. 1996. Herpetologica 52:89–97; Stephens and Wiens 2003. Biol. J. Linn. Soc. 79:577–610; Iverson et al. 2007. *In* Shaffer et al. [eds.], Chelonian Res. Monogr. [4]:85–106). Consistent with this relationship, the courtship pattern seen in *Deirochelys* may be a rudimentary, ancestral form of behavior which later evolved into titillation along the lineage of other extant genera. This would characterize Chicken Turtle courtship as a primitive (plesiomorphic) character state in the subfamily Deirochelyinae. An alternative interpretation, perhaps less likely, is that the waving of the male forearms in *D. reticularia* was derived as a vestigial relict of titillation. Evolutionary loss of elongate foreclaws and titillation behavior has presumably occurred in several species or subspecies of *Graptemys* (Vogt 1980. Tulane Stud. Zool. Bot. 22:17–48), *Trachemys* (Legler 1990. *In* Gibbons [ed.], Life History and Ecology of the Slider Turtle. Smithsonian Inst. Press, Washington, DC) and possibly *Malaclemys* (Seigel 1980. J. Herpetol. 14:420–421). These turtles, however, do not display the elements of forelimb movement exhibited by Chicken Turtles. In conclusion, the polarity of *Deirochelys* courtship behavior remains unclear and caution should be exercised when employing it as a phylogenetic character.

I thank Uwe Fritz for translations, Rudolf Wicker for sharing behavioral observations, and Dale Jackson for comments on the manuscript.

HYDROMEDUSA TECTIFERA **(**South American Snake-necked Turtle). **EPIZOIC TEMNOCEPHALIDA**. Soares et al. (2007. Ciência Rural 37[3]:901–903) recorded the occurrence of *Temnocephala* sp. in *Hydromedusa tectifera* (Pleurodira, Chelidae), in Encruzilhada do Sul (Rio Grande do Sul, Brazil) (30.5588889°S, 52.5825°W). We found the same species parasitized by Temnocephalida, on the Rio Grande do Sul at the Uruguayan border during field work in March, 1976, for the Project on Brazil-Uruguay Herpetofauna (Lema and Fabián-Beurmann 1977. Iheringia Zool. [50]:61–92), financed by Organization of American States.

Two specimens were caught in Livramento (Rio Grande do Sul) (30.8611111°S, 55.5552778°W), near the border with Uruguay, and in both the plastron was heavily infested with Temnocephalida. The Platyhelminthes were pedunculate and formed a high stratum, with the individuals very close to each other. Each worm was tubular and narrow, about one centimeter long, differing from the *Temnocephala* sp. described by Soares et al. (2007, *op. cit.*). The turtles were later joined in a tank with the emydid species *Trachemys dorbigni* that then became infested with these worms. The same infestation occurred with two specimens of the chelid *Acanthochelys spixii*, later put in the same tank. After two days the worms moved to the periphery of the plastron, after laying their eggs in the center and, after a few more days, the worms died and were removed and sent to the Department of Zoology, Universidade de São Paulo, S. Paulo, where they were identified as belonging to the genus *Temnocephala* Blanchard 1849, with species designation not specified.

MACROCHELYS TEMMINCKII (Alligator Snapping Turtle). **SUBMERGENCE TIME.** As part of a mark-recapture study of turtles in the Santa Fe River, Florida, USA, we continuously observed the behavior of an adult male *Macrochelys temminckii* (615 mm straight midline carapace length). On 12 December 2009, we initially encountered this animal at 2015 h in a clear, spring-fed area of the river (29.8473°N, 82.7092°W, datum

WGS84, elev. 6 m) in 22.3°C water as it walked along the bottom of the channel at a depth of ca. 2 m. At 2030 h, the turtle stopped moving and placed its head under a limestone ledge ca. 2.5 m deep. The turtle began moving again at 0430 h on 13 December and was hand captured as it headed to deeper water >4 m deep. During the entire 8 h 15 min period of continuous observation (from a distance of 5–6 m), the turtle remained submerged and did not surface to breathe air. This observation substantially increases the estimated maximum voluntary submergence time known for this species. This species had previously been thought to have a limited ability to remain submerged for long periods at warmer water temperatures (Ernst and Lovich. 2009. Turtles of the United States and Canada. Johns Hopkins Univ. Press, Baltimore. 827 pp.). In the only previous report of *M. temminckii* submergence time, Allen and Neill (1950. Ross Allen's Reptile Institute, Spec. Publ. No. 4) stated that this turtle cannot remain submerged for more than 40–50 min at water temperatures of 21–24°C.

RHINOCLEMMYS NASUTA (Chocoan River Turtle). **DIET AND FEEDING BEHAVIOR.** Published information on the diet of *Rhinoclemmys nasuta* is very limited, but the available reports indicate it is largely herbivorous, eating plant leaves, seeds, flowers, and fruits (Corredor-Londoño et al. 2007. Tortugas del Valle del Cauca. Corporación Autónoma Regional del Valle del Cauca, Santiago de Cali, Colombia. 74 pp.; Medem 1962. Rev. Acad. Colomb. Cien. Exac., Fís. Nat. 11:279–303). Medem (1962, *op. cit.*) also reported a grasshopper (Orthoptera) in stomach contents, and that in captivity they ate ripe plantains and raw meat. Other aquatic species of *Rhinoclemmys* have also been reported to have a primarily herbivorous diet, e.g., *R. funerea* (Moll and Jansen 1995. Biotropica 27:121–127) and *R. melanosterna* (Medem 1962, *op. cit.*). With respect to time and location of feeding activity, *R. funerea* was reported to make late afternoon and nocturnal forays to feed on land (Moll and Jansen 1995, *op. cit.*; Moll and Legler 1971. Bull. Los Angeles Co. Mus. Nat. Hist. [11]:1–102), whereas Medem (1962, *op. cit.*) stated that *R. melanosterna* was diurnal and would leave the water to feed on land.

While conducting sampling on the night of 30 June 2007, we encountered an individual of *Rhinoclemmys nasuta* on land eating carrion. Observations were made on Isla Palma, Department of Valle del Cauca, ca. 1.5 km off the Pacific Coast of Colombia (3.90019°N, 77.35597°W; WGS84). The island is in the tropical rain forest life zone (Holdridge 1967. Life Zone Ecology, rev. ed. Tropical Science Center, San Jose, Costa Rica. 206 pp.) and has average annual precipitation of ca. 6000 mm and 90% relative humidity. The predominant height of forest trees is between 10 and 50 m, with many shrubs and ferns in the understory (Castellanos 2003. Interacciones Tróficas y Espaciales de un Ensamblaje de Peces de Charcos Intermareales en un Acantilado Rocoso Tropical, Bahía Malaga-Pacífico Colombiano. Universidad del Valle, trabajo de grado. Cali, Colombia, 88 pp.; Montoya 2003. Estructura de la Comunidad de Gasterópodos: Diversidad, Distribución y Abundancia con Relación a la Heterogeneidad Espacial en Dos Acantilados Rocosos Intermareales de Isla Palma, Pacífico Colombiano. Universidad del Valle, trabajo de grado. Cali, Colombia, 82 pp.). We were sampling Río E (a first order stream) by wading upstream. At a point where we were going around an obstruction, a specimen of *R. nasuta* was spotted and captured while on land headed downhill quickly in the stream direction. The time was 2221 h local time, more than 4 h after nightfall. It seems clear the turtle had seen our lights and was retreating to the water. The specimen was a first-time capture (#747); a juvenile with carapace length = 129.1 mm and weight = 240 g. We noticed it smelled bad (usually they are odorless) and that it had what looked like feathers stuck to its head, and its

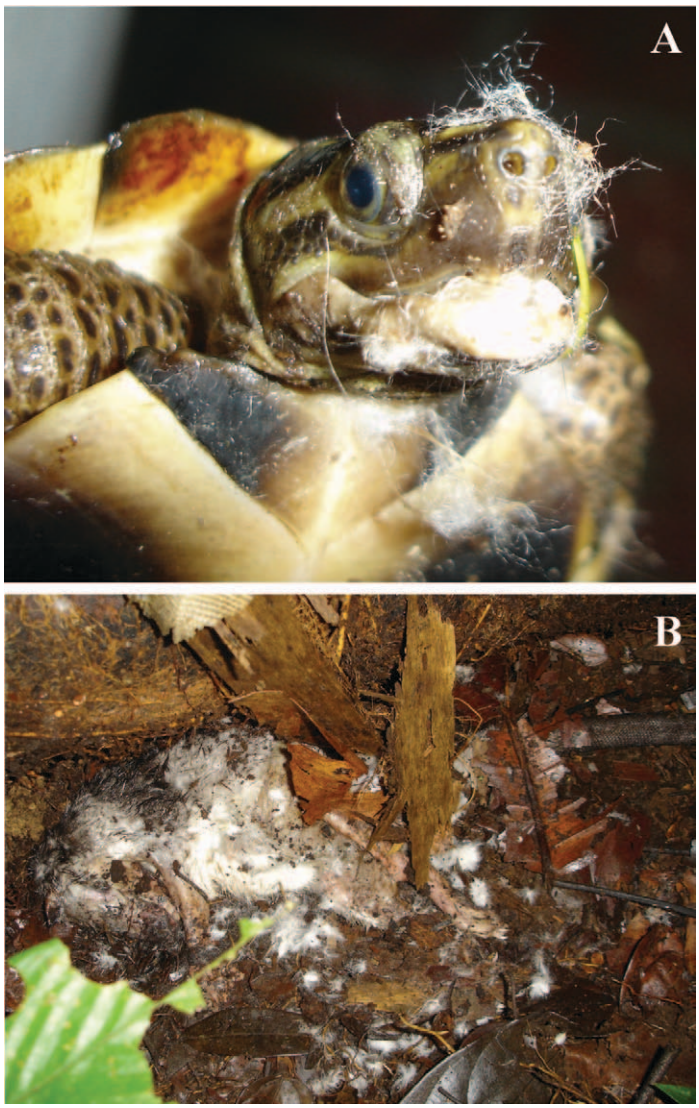

FIG. 1. A) Specimen of *Rhinoclemmys nasuta* shortly after capture with buccal cavity stuffed with fur. B) Body of the Water Opossum (*Chironectes minimus*) with the log lifted away. Note the left hindlimb has been stripped of fur down to the muscle. Photos by A. Quintero-Angel.

entire mouth was full of white "fluff" as it tried to bite. The turtle specimen had fur filling the buccal cavity, coming out the corners of the mouth, and little pieces stuck in scattered spots on the side of the head and forelimbs (Fig. 1A). We began a search to find what it had been eating and soon found a mammal body nearby. The body was up against and partly under a section of fallen tree trunk—about half the body under the log and half out, with a blow to the skull. The dead body was that of a male *Chironectes minimus* (Water Opossum or chucha de agua; Emmons and Feer 1990. Neotropical Rainforest Mammals: A Field Guide. University of Chicago Press, Chicago, Illinois. 281 pp.), a semi-aquatic opossum common on the island. There was an area at the front of the body where there was fur scattered about, and at least one hind leg had all the fur removed down to muscle (Fig. 1B). The straight-line distance from the water's edge to the *Chironectes* body was 3.80 m, but the over the surface distance would have been greater for the turtle to traverse because of the slope and its convexity.

The turtle was retained overnight in a container without access to water and was found to have swallowed the majority of the fur in the buccal cavity 9–10 h later. Generally speaking, aquatic and semi-aquatic turtles are restricted to feeding in the water (Bels et al. 2008. *In* Wyneken et al. [eds.], Biology of Turtles, pp. 187–212. CRC Press, Boca Raton, Florida), or returning to water to swallow after ingesting an item on land (Carr 2008. Southeast. Nat. 7:748–752; Winokur 1988. J. Morphol. 196:33–52). Our observations provide evidence that *R. nasuta* will feed on carrion, and that this feeding behavior may occur at night on land. It is not only capable of ingesting the food on land, but also swallowing while out of water.

We are indebted to the Dirección General Marítima (DIMAR) for allowing us access to the island, and to Laura Carolina Rubio for assistance in the field.

CROCODYLIA — CROCODILIANS

CAIMAN CROCODILUS (Spectacled Caiman). **PREY**. *Caiman crocodilus* is native to southeastern Chiapas, Mexico south to the coastal plain of Ecuador on the Pacific versant, and from northeastern Honduras to the southern edge of the Amazon Basin on the Atlantic versant (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago, Illinois. xx + 934 pp.). This species has been introduced on Isla de Juventud, Cuba, Puerto Rico (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville, Florida. xvi + 720 pp.), and in seven states of the United States, but is established only in Florida (Crother 2008. Scientific and Standard

FIG. 1. *In situ* photograph of dissected Spectacled Caiman (*Caiman crocodilus*) with Walking Catfish (*Clarius batrachus*) lodged in throat.

FIG. 2. Walking Catfish (*Clarius batrachus*) removed from throat of Spectacled Caiman (*Caiman crocodilus*) for size comparison.

English Names of Amphibians and Reptiles of North America. SSAR Herpetological Circular 37. 84 pp.). Little is known about the natural history of *C. crocodilus* in its introduced Florida range. With regards to diet, Ellis (1980. Copeia 1980:152–154) examined stomach contents of 30 *C. crocodilus* representing all age and size classes from Homestead Air Force Base, Miami-Dade Co., Florida, and recorded unidentified invertebrates and mammal hair, a Double-crested Cormorant (*Phalacrocorax auritus*), Southern Leopard Frogs and its tadpoles (*Lithobates sphenocephalus*), and fishes (native: *Centropomus undecimalis*, *Gambusia holbrooki*, *Ictalurus nebulosus*, *Lepomis macrochirus*, *Megalops atlanticus*, and *Poecilia latipinna*; nonindigenous: *Tilapia mariae*). Herein, we augment Ellis' diet data and report *C. crocodilus* preying upon the nonindigenous Walking Catfish (*Clarius batrachus*) in Florida.

On 4 February 2009 at 1500 h, an adult (94.8 cm SVL, 174 cm total length [TL]) *Caiman crocodilus* was observed basking on horizontally matted down Jamaica Swamp Sawgrass (*Cladium jamaicense*) in ca. 0.3 m water at the Frog City boat ramp, 7.6 mi W CR 997, Everglades National Park, Miami-Dade County (25.75976513°N, 80.59881673°W; datum: WGS84, elev. <1 m). This species is typically alert and "quite violent during initial capture" (Hertner 2006:267. Wilderness Environ. Med. 17:267–

270), however it allowed us to approach on an airboat and slip a noose around its head. The crocodilian's behavior was quite docile and allowed us to easily hoist it aboard and secure it for exotics removal from the park. The animal was later deposited in the Florida Museum of Natural History, University of Florida (UF 154567). While being dissected for diet contents and reproductive status, we found that the animal had a nonindigenous adult (25 cm TL) Walking Catfish (*Clarius batrachus*) lodged in its throat with both of the fish's pectoral fins (9.5 cm extended) penetrating through the esophagus. Page and Robins (2006. Raffles Bull. Zool. 54:455–457) classified this type of deleterious effect of an introduced species (i.e., catfish) as environmental degradation or ecological disruption. In Puerto Rico, at least 20 endangered Brown Pelicans (*Pelecanus occidentalis*) have been killed while attempting to prey on the nonindigenous Sailfin Catfish (*Pterygoplichthyes multiradiatus*) (Bunkley-Williams et al. 1994. Carrib. J. Sci. 30:90–94). The observed atypical behavior of our *C. crocodilus* suggests that it may have been affected by the catfish lodged in its throat. This is the first record of this nonindigenous crocodilian preying upon a nonindigenous catfish in Florida.

SQUAMATA — LIZARDS

ANOLIS GARMANI (Jamaican Giant Anole). **NEMATODE PARASITE.** Little is known about the parasites of *Anolis garmani*. Bundy et al. (1987. J. Helminthol. 61:77–83) reported encapsulated juvenile acanthocephalans (*Centrorhynchus spinosus*?) and an atractid nematode (*Cyrtosomum longicaudatum*) from *A. garmani* collected in Jamaica. We report a new host and distributional record for a second nematode parasite of *A. garmani* from Jamaica.

A single wild born adult *A. garmani* from an unknown locale in Jamaica was obtained on 18 November 1988 from a reptile dealer at Pet Farm in Miami, Florida, and housed at the Houston Zoological Gardens, Houston, Texas, where it remained until it died on 30 April 1989. A midventral incision was made to expose the entire length of the digestive tract. Four female nematodes were recovered from the stomach, cleared on glass slide with undiluted glycerol and identified with the use of a compound microscope as *Physaloptera squamatae*. These nematodes are deposited in the United States Parasite Collection (USNPC), Beltsville, Maryland as USNPC 85444; host was not accessioned.

McAllister and Bursey (2007. Proc. Oklahoma Acad. Sci. 87:65–67) provided a summary of the hosts and localities of *P. squamatae*, which has been previously reported to infect 17 species of lizards in the families Phrynosomatidae, Polychrotidae, Scincidae, Teiidae, and Tropiduridae, and a snake species in the family Viperidae. Localities of *P. squamatae* include the United States (Florida, Hawaii, Oklahoma, and Texas) and the Caribbean (Anguilla, Bahamas, Caicos Islands, Cayman Islands, and Cuba) (McAllister and Bursey, *op. cit.*). *Anolis garmani* represents a new host record for *P. squamatae*; Jamaica is a new locality record.

ARTHROSAURA RETICULATA (Yellow-bellied Arthrosaura). **ENDOPARASITES.** *Arthrosaura reticulata* (Gymnopthalmidae) is known from the Amazonian regions of Brazil, Ecuador, Peru, and Suriname (Avila-Pires 1995. Zool. Verh., Leiden 299:1–706). It is an inhabitant of leaf litter on the forest floor (Duellman 1978. Univ. Kansas Mus. Nat. Hist. Misc. Pub. 65:1–352). To our knowledge there are no reports of helminths from *A. reticulata*. The purpose of this note is to establish the initial helminth list for *A. reticulata*.

Twelve *A. reticulata* (4 female, 8 male, mean SVL = 47.5 mm ± 10.9 SD, range = 31–65 mm) from Reserva Faunistica Cuyabeno, Estación Biología da Universidad Católica (Quito) (0°S, 76.1166667°W; WGS 84, elev. 260 m) Sucumbios State, Ecuador collected March–April 1994 by LJV and deposited in the herpetology collection of the Sam Noble Oklahoma Museum of Natural History, Norman, Oklahoma as OMNH 36443–36454 were examined for endoparasites.

The body cavities were opened and the intestines removed and examined under a dissecting microscope. These specimens had been used previously for an ecological study (Vitt and Zani 1996. Can. J. Zool. 74:1313–1335); the stomachs were not available for examination. All endoparasites were found in the small intestines. Trematodes were regressively stained in haematoxylin and mounted in balsam. Nematodes were cleared in glycerol on a microscope slide. All were studied under a compound microscope. We found *Mesocoelium monas* (Trematoda), *Cosmocerca vrcibradici* (Nematoda) and *Oswaldocruzia vitti* (Nematoda). Two individuals of *M. monas* (prevalence [number infected/number examined x 100] = 8%, mean intensity [average number of parasites per infected lizard] = 2), 7 (1 male, 6 female) individuals of *C. vrcibradici* (prevalence = 42%, mean intensity = 1.4 ± 0.5 SD, range = 1–2), and 20 (5 male, 15 female) individuals of *O. vitti* (prevalence = 50%, mean intensity = 3.3 ± 2.9 SD, range = 1–7) were in the sample. Helminths were deposited in the United States National Parasite Collection, Beltsville, Maryland USA as: *Mesocoelium monas* (USNPC 102886), *Cosmocerca vrcibradici* (USNPC 102887), *Oswaldocruzia vitti* (USNPC 102888).

Mesocoelium monas is cosmopolitan in distribution and a recent host list is available (Goldberg et al. 2009. Comp. Parasitol.76:58–83). In Ecuador, it has been previously reported in the gymnophthalmid lizard *Alopoglossus angulatus* (Goldberg et al. 2007. Herpetol. J. 17:269–272). *Cosmocerca vrcibradici* is known from Brazil and Ecuador. *Oswaldocruzia vitti* is known from Brazil, Ecuador, and Peru. Both species were described from the gymnophthalmid lizards *Priondactylus eigenmanni* and *P. oshaughnessyi* (Bursey and Goldberg 2004. J. Parasitol. 90:140–145). *Cosmocerca vrcibradici* has been reported from *Al. angulatus* and *Al. atriventris* (Goldberg et al. 2007, *op. cit.*), the polychrotid lizard *Anolis fuscoauratus* (Goldberg et al. 2006a. Phyllomedusa 5:83–86) and the tropidurid lizard, *Uranoscodon superciliosus* (Bursey et al. 2005. J. Parsitol. 91:1395–1398). *Oswaldocruzia vitti* has been reported from *Al. angulatus* and *Al. atriventris* (Goldberg et al. 2007, *op. cit.*), *An. fuscoauratus* (Goldberg et al. 2006a, *op. cit*.), *An. punctatus* (Goldberg et al. 2006b. Amphibia-Reptilia 27:575–579), and the tropidurid lizards *Plica plica and P. umbra* (Goldberg et al. 2009. Herpetol. J. 19:49–52). *Arthrosaura reticulata* represents a new host record for *Mesocoelium monas*, *Cosmocerca vrcibradici*, and *Oswaldocruzia vitti*.

We thank Olivia Mac (Whittier College) for assistance with dissections.

ASPIDOSCELIS CALIDIPES (Río Tepalcatepec Valley Whiptail). **REPRODUCTION**. *Aspidoscelis calidipes*, a small member of the *A. sexlineata* species group, was described from 18 specimens from the Tepalcatepec Valley, Michoacán, México, by Duellman (1955. Occas. Pap. Mus. Zool., Univ. Michigan 574:1–7). It has also been reported from Guerrero (Pérez-Ramos et al. 2000. An. Inst. Biol. Univ. Nac. Autón. Méx., Ser. Zool. 71[1]:21–40; Pérez-Ramos and Saldaña-De la Riva 2005. Rev. Zool. 16:16–24). Variation, distribution, and ecology of the species were discussed by Duellman (1960. Copeia 1960:97–101) and summarized by Duellman and Zweifel (1962. Bull Am. Mus. Nat. Hist. 123:155–210) based on 136 specimens from Michoacán. Here, we provide reproductive data (clutch range and mean ± SE, SVL ranges and mean ± SE, and ovarian egg range and mean ± SE) for *A. calidipes* for which only a mean for clutch size has been presented in a table of comparisons with other species (Walker 1981a. Am. Midl. Nat. 105:217–224).

We examined 50 of the 52 specimens labeled as *A. calidipes* from University of Kansas Natural History Museum (KU, N = 15) and University of Colorado Museum (UCM, N = 37). We also examined specimens of this species from Museo de Zoología "Alfonso L. Herrera," Facultad de Ciencias (MZFC, N = 8) y del Instituto de Biología (IBH), Universidad Nacional Autónoma de México. Included from Michoacán are: 25.6 km S of Arteaga [3 December 1950 (KU 29747, N = 1)]; 19.4 km SSW of Apatzingán [30 November 1950 (KU 29748, N = 1)]; 1.6 km S of Capirio [26 August 1960 (KU 62602–62612, N = 11)]; Capirio [25 April 1956 (KU 69036–69037, N = 2)]; 8.0 km N of Nueva Italia [4 June 1972 (UCM 49687–49692, N = 6)]; 17.6 m S of Nueva Italia [5 June 1972 (UCM 49693, N = 1); 7 June 1972 (UCM 49694–49697, N = 4); 10 June 1972 (UCM 49698–49723, N = 26)]. Included from Guerrero are: Juntas de Cujarán [11 May 1979 (MZFC 701, 703, N = 2); 12 May 1979 (MZFC 702, 706, 708, N = 3); 11 June 1979 (MZFC 704, N = 1); 12 June 1979 (MZFC 700, 705, N = 2)].

The pooled KU and UCM samples from Michoacán included by sizes (as 5 mm SVL increments) these frequencies (in parens) for 19 females followed by 31 males: 40–44 (0:1); 45–49 (1:0); 50–54 (3:1); 55–59 (8:1); 60–64 (4:6); 65–69 (3:14); 70–74 (0:5); and 75–79 (0:3). The MZFC sample from Guerrero included by sizes (as 5 mm SVL increments) these frequencies (in paren) for a female followed by 7 males: 55–59 (0:1); 60–64 (0:3); 65–69 (1:2); and 70–74 (0:1). The smallest gravid female of 52 mm SVL among the specimens of *A. calidipes* is comparable to the smallest gravid females reported by Walker (1981a, *op. cit.*) and Walker (1981b. J. Herpetol. 15:321–328) for *A. parvisocia* from Puebla (50 mm SVL) and Oaxaca (52 mm SVL). Each of the following statements for a SVL group from Michoacán includes the numbers of gravid females followed by clutch size based on the same or a smaller number of lizards with undamaged eggs. In *A. calidipes* 1 of 3 (33.3%) females 50–54 mm SVL had a clutch of 2 eggs. Among females 55–59 mm SVL, 5 of 8 (62.5%) had clutches of 1–2 eggs (mean = 1.8). Among females 60–64 mm SVL, 3 of 4 (75%) had clutches of 3–4 eggs (mean = 3.3). Among females 65–69 mm, 3 of 3 (100%) had clutches of 1–4 eggs (mean = 2.3). The female of 67 mm SVL from Guerrero had a clutch of 3 eggs. Overall, only two specimens of 44 and 49 mm SVL were arguably sub-adults. Females with data from Michoacán (N = 12) had clutches (sample size in each category in parens) of 1 (2), 2 (6), 3 (2), and 4 (2); mean clutch size, SVL, and ovarian egg size for these females were 2.33 ± 0.28 (1–4) eggs, 60.1 ± 1.03 (52–65) mm, and 5.61 ± 0.36 mm, respectively. No correlation existed between clutch size and SVL in the sample of 12 gravid females of *A. calidipes* (adjusted r^2 = -0.0086, P = 0.3636), a finding that may reflect sample size. However, lack of a correlation persisted after pooling the gravid specimen of *A. calidipes* from Guerrero with the sample from Michoacán. It is noteworthy to mention that mean clutch size and SVL for 85 *A. parvisocia* gravid females from Puebla and Oaxaca were 1.78 ± 0.06 (1–4) eggs and 59.5 ± 0.38 (50–69) mm; thus, a correlation existed between clutch size and SVL in this species (adjusted r^2 = 0.165, P = 0.0001) (Walker 1981a, *op. cit.*).

We are grateful to Shi-Kuei Wu (UCM), William E. Duellman (KU), and Oscar Flores-Villela and Adrián Nieto-Montes de Oca (MZFC) for the opportunity to examine specimens in their care.

WALKER**, Department of Biological Sciences, University of Arkansas, Fayetteville, Arkansas 72701, USA (e-mail: jmwalker@uark.edu); **EDMUNDO PEREZ-RAMOS,** Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, México, Distrito Federal 04510, México (e-mail: ermuno@servidor.unam.mx).

ASPIDOSCELIS COSTATA GRISEOCEPHALA (Blue-throated Whiptail). **REPRODUCTION**. *Aspidoscelis costata griseocephala* (*sensu* Reeder et al. 2002. Am. Mus. Novit. 3365:1–61) is among many named, but biologically poorly known reptiles from remote areas of México. Zweifel (1959. Bull. Am. Mus. Nat. Hist. 117:57–116) described the subspecies as *Cnemidophorus sacki griseocephalus* based on 78 specimens from the type locality (18.2 km E of Navojoa, Sonora) and other sites in the states of Sonora and Sinaloa. Duellman and Zweifel (1962. Bull. Am. Mus. Nat. Hist. 123:155–210) reallocated the subspecies to *C. costatus griseocephalus* (= *A. costata griseocephala*; Reeder et al., *op. cit.*). Wright (1993. *In* Wright and Vitt [eds.]. Biology of Whiptail Lizards (Genus *Cnemidophorus*), pp. 27–81. Oklahoma Mus. Nat. Hist., Norman, Oklahoma) provided no data in support of his use of the name *A. burti griseocephala*. Here, I present reproductive data (clutch ranges and mean ± SE, SVL ranges and mean ± SE) for a form that Bogert and Oliver (1945. Bull. Am. Mus. Nat. Hist. 83:297–426) and Zweifel (*op. cit.*) reported only limited clutch and SVL observations.

I examined 62 specimens labeled as *C. costatus griseocephalus* (= *A. costata griseocephala*) from the California Academy of Sciences (CAS) collected by A. E. Greer and F. W. Burley at these five sites in Pacific coastal Sinaloa: 10.6 km N of Los Mochis on Hwy 15 [15 June 1963 (CAS 115004, N = 1); 21 July 1963 (115683–115695, N = 13)]; 15.7 km NE of Topolobampo on Los Mochis Road [21 July 1963 (CAS 115681–115682, N = 2)]; 16.5 km N of Río de Fuerte on Hwy 15 [22 July1963 (CAS 115707–115710, N = 4); 23 July 1963 (CAS 115711–115712, N = 2)]; 4.3 km N of Masiaca on Hwy 15 [23 July 1963 (CAS 115769, N = 1); 24 July 1963 (CAS 115772–115781, 115786–115787, 115789, N = 13)]; and 49.4 km S of Masiaca on Hwy 15 [23 July 1963 (CAS 115719–115744, N = 26)]. I obtained size (as SVL to the nearest 1 mm) for all specimens in the CAS sample. Females were dissected to identify the number and measure oviductal eggs and ovarian follicles (this was precluded in three damaged gravid females).

A male-biased sex ratio of ca. 1.6:1 (38:24) in the CAS sample of *A. c. griseocephala* approached the ca. 2:1 (129 males:64 females) ratio observed in *A. costata nigrigularis* (Walker 2008a. Herpetol. Rev. 39:86–87), but much less skewed than the ca. 3:1 (187 males:68 females) ratio observed in *A. costata huico* (Walker 2008b. Herpetol. Rev. 39:85–86). None of the 16 (three damaged) gravid females of *A. c. griseocephala* contained oviductal eggs; all had yolked ovarian follicles of 3.5–10.0 mm in diameter. Bias in the sex ratio of each of these taxa may pertain to secretive female behavior during egg maturation and oviposition that make them less susceptible to collection than other adults. Alternatively, shorter life expectancy in females is a non-mutually exclusive explanation that may also contribute to the male-biased sex ratio. The latter may be reflected by the relative male:female numbers, respectively (in parens), by 10-mm SVL increments (where applicable) in the CAS sample: 50–59 (0:1); 60–69 mm (4:8); 70–79 mm (8:6); 80–89 mm (8:7); 90–99 mm (11:2); 100–109 mm (3:0); 110–118 mm (4:0). Assuming any secretive behavior by adult females is unrelated to their size, *A. c. griseocephala* appears sexually dimorphic in favor of males.

Females of *A. c. griseocephala* attain reproductive maturity at a small body size (ca. 61–66 mm SVL) similar to *A. costata barrancarum* in southwestern Chihuahua (Walker et al. 2004. Herpetol. Rev. 34:366), *A. c. nigrigularis* in Sinaloa (Walker 2008a, *op. cit.*), and *A. c. huico* in Sinaloa and Nayarit (Walker 2008b, *op. cit.*). In *A. c. griseocephala*, four (50%, one damaged) females 60–69 mm SVL had clutches of 2–3 eggs (= 2.3, N = 3). Among females 70–79 mm SVL, 5 (83.3%, one damaged) were gravid; clutch size was 2–5 eggs (mean = 3.0 ± 0.8 SD, N = 4). Among females 80–89 mm SVL, 5 (71.4%, one damaged) were gravid; clutch size was 4–6 eggs (mean = 5.0 ± 0.8 SD, N = 4). Among females 90–99 mm SVL, two (100%) were gravid; clutch size was five eggs (mean = 5.0, N = 2). For the period 15 June–24 July 1963, 13 females with data had clutches (sample size in each category in parens) of 2 (3), 3 (3), 4 (2), 5 (4), and 6 (1); mean clutch size and SVL for these females were 3.8 ± 0.37 (2–6) eggs and 78.7 ± 2.68 (66–96) mm, respectively. A strong relationship exists between clutch size and SVL (based on adjusted $r^2 = 0.67$, $P = 0.0004$, N = 13). Data for the CAS sample established these additional reproductive characteristics for *A. c. griseocephala;* SVL of all adult males, 86.7 ± 2.27 (62–115, N = 38) mm; SVL of all adult females, 76.0 ± 2.12 (61–96, N = 23) mm; reproductive season, June–July (this study) and into late August (Zweifel, *op. cit.*) and perhaps longer; and reproductive potential, multiple clutches based on early maturation of both sexes at small body sizes in an extended activity cycle in subtropical México.

I thank Robert C. Drewes (CAS) for the opportunity to examine specimens in his care. This note was materially improved by the editorial expertise of Marc P. Hayes.

ASPIDOSCELIS SCALARIS SEPTEMVITTATA (Big Bend Spotted Whiptail). **ENDOPARASITES.** *Aspidoscelis scalaris septemvittata* is known from Northern Chihuahuan Desert, populations exist in the Big Bend region of Texas and adjacent Mexico where they can be found in the states of Chihuahua, Coahuila, Durango, and Zacatecas (Leavitt 2009. *In* Jones and Lovich. Lizards of the American Southwest, pp. 378–381. Rio Nuevo Publishers, Tucson, Arizona). Herein, we present data on a high parasite load and a new species of parasite for *A. s. septemvittata*.

Scudday and Dixon (1973. Southwest. Nat. 18:279–289) reported 17 of 74 stomachs of *A. s. septemvittata* from Trans-Pecos, Texas contained nematodes with a maximum of 15 per stomach. During a gut content analysis of 27 *A. s. septemvittata* from Big Bend National Park, Brewster Co., Texas (Leavitt 2007. MS thesis. Sul Ross State University. 126 pp.), 25 of 27 stomachs analyzed contained nematodes. We found an average of 7.76 ± 5.71 (range: 0–23) nematodes per stomach in this sample. A sympatric population of 19 *Aspidoscelis marmorata*, collected at the same time, only contained 2 members with nematode infestation.

Two male *A. s. septemvittata* (SRSU 6637, 6661) were examined for endoparasite identification. We identified one species of Nematoda, *Abbreviata terrapenis*, from both individuals. *Abbreviata terrapenis* was originally described from the chelonian *Terrapene ornata* (Hill 1941. Trans. Am. Micro.

Soc. 60:59–64). It has also been reported for four other species of lizards, including *Sceloporus jarrovii* (Goldberg et al. 1996. Am. Mid. Nat. 135:299–309), *Aspidoscelis sonorae* (Goldberg et al. 1997. Great Basin Nat. 57:273–277), *Aspidoscelis tigris* (Goldberg et al 1997, *op. cit.*), *Crotaphytus collaris* (McAllister et al. 2008. Comp. Parasitol. 75:241–254), and three species of snakes including *Thamnophis cyrtopsis* (Goldberg and Bursey 2002. W. N. Am. Nat. 62:160–169), *Crotalus lepidus klauberi* (Goldberg et al. 2002. J. Wild. Dis. 38:453–456), and *Coluber constrictor* (McAllister et al. 2008, *op. cit.*). Voucher helminths from this population of *A. terrapenis* have been sent to the United States National Parasite Collection, USNPC, Belltsville, Maryland, USA as: *A. terrapenis* (USNPC 101523).

Permission to collect lizards was granted to D. J. Leavitt by National Park Service permit number BIBE-2006-SCI-001.

COLEONYX BREVIS (Texas Banded Gecko). **DIET.** Little has been published about the diet of *Coleonyx brevis*, with only one published study focusing on the subject (Punzo 1974. Copeia 1974:779–780). Here we report on the diet of *C. brevis* from Coahuila, Mexico.

We examined 42 specimens of *C. brevis* from the collection of the Laboratorio de Ecología, UBIPRO – FES-Iztacalal UNAM. These specimens were collected from Coahuila, Mexico, primarily 80 km S Químicas del Rey (26.443333°N, 103.035889°W, datum: WGS84; elev. 1091 m), but also from additional sites in the area S of Químicas del Rey. We dissected lizards to obtain information on diets. We identified each prey item to order or family as possible, and measured the length and width of each item using an electronic caliper (to nearest 0.1 mm). We estimated prey volume using the formula for a prolate spheroid.

Of the 42 specimens examined, only 18 (43%) contained prey in their stomachs. Numerically, isopterans (termites) were the most important prey items, and represented >75% of the prey items consumed (Table 1). Volumetrically, termites were also the most important prey items, followed by homopterans. However, isopterans were only found in 5 of the 18 stomachs that contained prey, suggesting they are likely patchy prey. Punzo (1974, *op. cit.*) found that the most important prey item numerically were beetles for a population of *C. brevis* from Texas. Interestingly, Punzo (1974, *op cit.*) found no isopterans in the stomachs he examined. Parker and Pianka (1974. Copeia 1974:528–531) found termites were numerically an important item in the diets of *C. variegatus*, but this importance varied seasonally. It may be that isopterans are more available in the environment in the vicinity of the populations our specimens were collected from.

TABLE 1. Diet of *Coleonyx brevis* from Chiahuahua, Mexico.

Prey Category	Number (%)	Percent Volume	Frequency
Araneae	1 (1.35)	0.63	1
Coleoptera			
Adult	4 (5.41)	3.75	3
Larvae	4 (5.41)	< 0.5	2
Diptera	3 (4.05)	8.13	2
Hemiptera	1 (1.35)	1.25	1
Homoptera	1 (1.35)	21.25	1
Isoptera	56 (75.7)	38.75	5
Lepidoptera			
Larvae	1 (1.35)	6.88	1
Orthoptera			
Acrididae	3 (4.05)	19.38	3

Indeed, observations published in association with the collection data indicate that the lizards were "feeding on huge numbers of flying ants [actually termites]" (Smith et al. 2005. Bull. Chicago Herpetol. Soc. 40:45–51). Thus, the presence of termites in *Coleonyx* diets may be temporally variable depending on termite abundance in the environment. Further research is required to determine how much the differences in diets reflect differences in prey availability or differences in prey selectivity.

Submitted by **ALLISON BOYD, CHRISTOPHER B. DAYER, , KRISTEN E. WINTER, JOSHUA J. SCHULTE, GEOFFREY R. SMITH,** Department of Biology, Denison University, Granville, Ohio 43023, USA (e-mail: smithg@denison.edu); and **JULIO A. LEMOS-ESPINAL**, Laboratorio de Ecología, Tecnología y Prototipos, Facultad de Estudios Superiores Iztacala, UNAM, Apartado Postal 314, Avenida de Los Barrios No. 1, Los Reyes Iztacala, Tlalnepantla, Estado de México, 54090 México (e-mail: lemos@servidor.unam.mx)

COPHOSAURUS TEXANUS (Greater Earless Lizard). **MULTIPLE TAILS**. Records of bifid and trifid-tail regeneration in lizards have previously been published for *Plestiodon* (=*Eumeces*) *egregius* (Taylor 1935. Univ. Kansas Sci. 23:1–643), *Elgaria multicarinata* (Banta 1963. Turtox News 41:207), *Christinus* (=*Phyllodactylus*) *marmoratus* (Crouch 1969. Wildlife in Australia 6:101), *Anolis sagrei* (Goin and Goin 1971. Introduction to Herpetology, 2nd ed. W. H. Freeman and Co., San Francisco, California. 353 pp.), *Sceloporus occidentalis* (Clark 1973. HISS News-J. 1:158), *Plestiodon* (=*Eumeces*) *fasciatus* (Scott 1982. Herpetol. Rev. 13:46), and *Microlophus bilineatus* (Colwell 1992. Herpetol. Rev. 23:118). Herein, we report the first record of a trifid-tailed *Cophosaurus texanus* found in the Chihuahuan Desert of Trans-Pecos, Texas.

On 7 September 2008, at 0020 h, an adult male *C. texanus* (SVL 75 mm; 13.8 g) with three irregular regenerated tails was found resting on sandy substrate surrounded by Chihuahuan Desert scrub vegetation, 1.6 km SE of the headquarters complex of the Indio Mountains Research Station, located ca. 40 km SW of Van Horn, Hudspeth Co., Texas (30.773392°N, 105.012430°W,

FIG. 1. An adult male trifid-tailed *Cophosaurus texanus* caught at Indio Mountains Research Station, Hudspeth County, Texas.

WGS84; 1233 m elev.). The trifurcation point was positioned 24.0 mm posterior from the cloaca (Fig. 1). Length of the large middle tail was 30.0 mm and the other two were 6.0 mm (left side) and 4.0 mm (right side), respectively.

It has been suggested that multiple regenerated tails are mostly the result of new tails growing from irregular cuts due to injury (Clark 1973, *op. cit*.; Goin and Goin 1971, *op. cit.*), which appears to be the case for this lizard. All three tails were clearly regenerated as indicated by the re-grown surfaces having smaller scales and an absence of color pattern like that found on the non-regenerated tail section. The lizard is deposited in the Herpetology Collection, Laboratory for Environmental Biology, Centennial Museum, at the University of Texas at El Paso (UTEP 19872). We thank A. F. Scott and R. Webb who kindly provided us with some of the literature sources.

Submitted by **VICENTE MATA-SILVA** (e-mail: vmata@miners.utep.edu), **ARTURO ROCHA**, **ANTHONY GANDARA**, and **JERRY D. JOHNSON**, Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968, USA.

CROTAPHYTUS VESTIGIUM (Baja Black-collared Lizard). **ENDOPARASITES.** *Crotaphytus vestigium* occurs from the peninsular ranges of southern California to the southern margin of the Magdalena Plain in Baja California Sur, México (McGuire 1996. Bull. Carnegie Mus. Nat. Hist. 32:1–143.). To our knowledge there are no reports of helminths for this species. The purpose of this note is to establish the initial helminth list for *C. vestigium*.

Two nematodes were found in one female *C. vestigium* (SVL = 79 mm) collected July 1949 at Bahía de Concepción, Baja California Sur, México (26.750000°N, 111.883333°W, WGS84; elev. 2 m) and deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA as LACM 63172. The nematodes were cleared in a drop of glycerol on a glass slide, cover-slipped and identified as two adult female *Thubunaea iquanae*. They were deposited in the United States National Parasite Collection, Beltsville, Maryland, UDSA as USNPC (102963).

Thubunaea iguanae is a common stomach parasite of lizards from the southwestern United States and Mexico (Baker 1987. Mem. Univ. Newfoundland, Occas. Pap. Biol. 11:1–325) and also occurs in colubrid snakes (Goldberg and Bursey 2001. Bull. South. California Acad. Sci. 100:109–116). It is in the family Physalopteridae, which utilizes intermediate insect hosts (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Tranmission, 2nd ed. CABI Publishing, Oxfordshire, UK. 650 pp.). *Crotaphytus vestigium* represents a new host record for *Thubunaea iguanae*.

We thank Christine Thacker (LACM) for permission to examine *C. vestigium*.

BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

CTENOTUS HELENAE (Helen's Comb-Eared Skink). **HERMAPHRODITISM**. On 20 November 2008, SEG and ERP caught a hermaphroditic adult *Ctenotus helenae* (88 mm SVL, 14.1 g, 117 mm tail with an 87 mm regenerated portion) in a pitfall trap at their Red Sands study site (28.19397ºS, 123.58247ºE, datum WGS 84; elev. 430 m) in the Great Victoria Desert of Western Australia. During examination for sexual condition and diet, the specimen was found to have a regular testicle on its right side but an ovotestis on its left side. The latter consisted of a smaller testicle with a cluster of ovarian follicles attached antero-laterally. The follicle cluster was separated from the left testicle by a thin brown sheet of tissue not typically present on the gonads of this species. The right testicle measured (maximum width × length) 5.0 × 10.4 mm, the left testicle was 3.5 × 6.8 mm, and the four ovarian follicles were all between 0.9 and 3.0 mm in maximum diameter. The left half of the cloaca lacked a hemipenis but the right hemipenis was everted. Functionality as a male seems likely due to the fully developed appearance of the testicles and everted right hemipenis. The lizard appeared normal

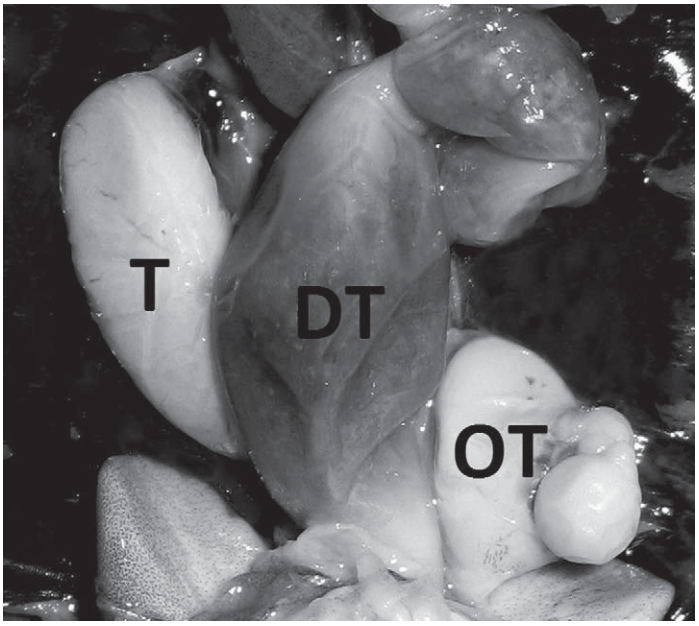

FIG. 1. Posteroventral body cavity of a hermaphroditic *Ctenotus helenae*. Labels indicate the testis (T), ovotestis (OT) and digestive tract (DT). Photograph by S. Goodyear.

and uninjured besides the regenerated tail and a few missing scales. Horner (1991. Skinks of the Northern Territory. Northern Territory Government Printing Office. Darwin, Australia. 174 pp.) reports a maximum 95.0 mm SVL for this species. Of conspecifics collected by ERP, fresh SVL (mm) for 60 males averaged 76.6 with a maximum of 95.0 whereas fresh SVL for 83 females averaged 83.3 with a maximum of 98.0. These data show the hermaphrodite is typical but larger in size. The skink was captured during the September–February breeding season for the species (Horner, *op. cit*.).

Few reports of intersex observations among lizards exist. Tayler (1918. Proc. Zool. Soc. London 1918:223–230) described a *Lacerta viridis* with both left and right ovotestes. Badir (1958. Zeit. Wiss. Zool. 160:290–351) found a *Chalcides ocellatus* with a right gonad containing mostly ovarian follicles attached to a nonfunctional testicular rudiment. Bons and Bons (1969. C. R. Acad. Sci. Paris 268:695–696) reported an *Ophisaurus koelikeri* with a full set of male and female reproductive structures. Darevsky et al. (1978. Copeia 1978:201–207) found a *Lacerta armeniaca* with a right ovotestis. Goldberg (1989. Copeia 1989:486–488) reported a *Sceloporus occidentalis* with left and right ovotestes consisting of testes attached to ovarian follicles clustered anteriorly and Brown (2008. Biawak 2008:87–88) described a *Varanus acanthurus* with a right testicle and left ovary, oviducts and uterine tissue. In our case, ERP collected and examined nearly 30,000 lizards before we found this exceptional one.

We deposited the specimen in the Western Australian Museum (WAM R169499). We thank Marc Hayes and Jackson Shedd for comments on the manuscript.

GAMBELIA WISLIZENII (Long-Nosed Leopard Lizard). **ESCAPE BEHAVIOR/ SWIMMING AND FLOATING**. Swimming and floating abilities in lizard species that inhabit desert environments are not often observed under natural conditions. Here, I report the aquatic behavior of an inhabitant of the xeric Mojave Desert of the southwestern United States. An account describing aquatic escape behavior of a closely related species, the Eastern Collared Lizard (*Crotaphytus collaris collaris*) (McAllister 1983. Herpetol. Rev. 14:11), reported individuals avoiding capture by running into a quarry pond, inflating their lungs, and floating or actively swimming to return to shore. A recent account (Estrada-Rodriguez and Leyva Pacheco 2007. Herpetol. Rev. 38:84–85) documents the swimming ability of the Coahuila Fringe-toed Lizard (*Uma exsul*), a sand dune specialist in Coahuila, Mexico. On several occasions these lizards were observed swimming and floating across open expanses of water between dune complexes with a "serpentine pattern that was especially evident in the tail, this animal would stop periodically to float and to change direction." Carpenter and Ferguson (1977. *In* Gans and Tinkle [eds.] Biology of the Reptilia, vol. 7, pp. 335–554. Academic Press, London) did not consider swimming behavior as "steryotyped" and therefore it was not included in their chapter (C. C. Carpenter, pers. comm.).

On 12 July 1990, while I was approaching a remote pond at Well Site (J-12) on the edge of Fortymile Canyon near the southern boundary of the Nevada Test Site, Nye Co., Nevada, USA, an

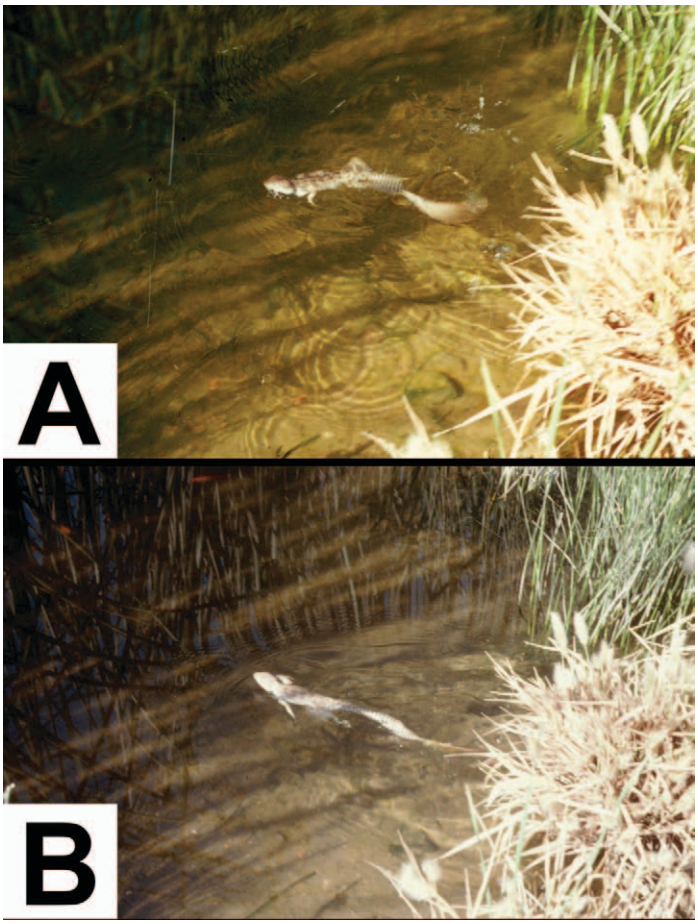

FIG. 1. A) Adult female Long-nosed Leopard Lizard (*Gambelia wislizenii*) swimming with serpentine motion of its body and tail. B) Hand over hand paddling of anterior legs while swimming.

adult female *Gambelia wislizenii* ran across the sandy soils ca. 3 m in front of me and sprang directly into the water, swam briefly to an adjacent cat-tail (*Typha latifolia*) and perched there half submerged. The lizard stayed perched in this position for a few minutes until it was captured. Astounded by this unusual escape behavior which took place instantaneously as I approached the pond, I attempted to see if the lizard would repeat this behavior and document it with photographs. Subsequently, the lizard was placed gently in the shallow water at the edge of the pond and it proceeded to swim away from the shore several meters (Figs. 1A, B), with its body and tail undulating in a serpentine pattern, and its legs appearing to be paddling alternately. Ultimately, the lizard remained in the water, appeared to inflate its lungs, and floated into the reeds.

I thank C. C. Carpenter for his comments on this and an earlier version of this observational note, and K. Nussear, K. Phillips, R. Fisher, and J. Richmond for their reviews. I also thank C. Dull and P. Greger for their assistance in the field, and K. Nolte and K. Drake for preparing the figures. I gratefully acknowledge the U.S. Department of Energy, National Nuclear Security Administration for continued access to our study sites.

GYMNODACTYLUS DARWINII (Darwin's Atlantic Rainforest Naked-toed Gecko; lagartixa-de-dedos-nus da Mata Atlântica). **COMMUNAL OVIPOSITION**. Little has been published on phyllodactylid geckos of the genus *Gymnodactylus* regarding reproductive behavior or biology. Aside from the works by Vitt (1986. Copeia 1986:773–786) and Colli et al. (2003. J. Herpetol. 37:694–706), there are only sporadic records on *Gymnodactylus* reproduction. *Gymnodactylus geckoides*, an endemic species of the Caatinga bioregion, appears to produce eggs continuously throughout the year with individual females producing at least two clutches per year of one egg each (Vitt 1986, *op. cit.*). Alternatively, *G. amarali*, an endemic species of the Cerrado region, has a pattern that differs from *G. geckoides*, with one or two (more frequently two) eggs per clutch, with reproduction concentrated during the dry season (May to September), although reproductive individuals have been found throughout the year (Colli 2003, *op. cit.*). Despite the similar size of adult females, *G. geckoides* lays smaller clutches of larger eggs than *G. amarali* (Colli 2003, *op. cit.*). Vanzolini (1953, *op. cit.*) reported that a female of *G. darwinii*, an endemic species of the Atlantic Rain Forest bioregion, captured on 2 July 1950 in the São Sebastião island, São Paulo state, after approximately six months in captivity, produced two eggs on 26 December in an oval nest. In addition, he also described the egg-laying behavior. Righi et al. (2004. Herpetol. Rev. 35:395–396) mentioned that *G. guttulatus*, known only from the vicinity of Diamantina municipality, in Espinhaço Range, Minas Gerais state, has eggs with almost spherical shape. These anecdotal accounts are the only published data on reproduction in *Gymnodactylus* species. Herein we report evidence of communal nesting for the common Atlantic Rainforest Naked-toed Gecko, *Gymnodactylus darwinii*.

On 26 February 2009, one of us (JC) found six small, uniformly white, hard-shelled calcareous eggs, slightly oval (mean length = 10.2 ± 0.31305; mean width = 8.55 ± 0.130384) in a disturbed area in the vicinity of Canavieiras municipality (15.66908333°S, 38.98469444°W; datum WGS84, elev. ca. 10 m), Bahia state, Brazil. They were identified as those of *G. darwinii* based on size and general appearance, and the fact that this is the only species of *Gymnodactylus* that occurs in the region. The eggs were found together under a fallen log, in a cavity with fragments of rotten wood. We could not obtain precise dimensions on the nest (ca. 50 mm), as it was partially destroyed when found. In the same fallen log, in other cavities, we captured seven adult specimens of *G. darwinii*, apparently using this microhabitat gregariously. The nest was collected and two eggs hatched in a terrarium at the laboratory, one after 95 days, and the other after 109 days from collection. The hatchlings measured 21.8 and 21.95 SVL and 21.4 and 21.6 mm tail length, respectively. The other four eggs died.

Gekkotan lizards usually produce one or two white eggs per clutch, and they may lay several clutches per year (Kluge 1967. Bull. Am. Mus. Nat. Hist. 135:1–60; Fitch 1970. Misc. Publ.Univ. Kansas Mus. Nat. Hist. 52:1–247). Communal egg-laying or nesting appears to be widespread in lizards, particularly geckos, even involving more than one species (e.g., Krysko et al. 2003. Amphibia-Reptilia 24:390–396; Oda 2004. Acta Amazonica 34:331–332). Communal oviposition was defined by Espinoza and Lobo (1996. Herpetol. Nat. Hist. 4:65–68) as "the non-incidental deposition of eggs at a shared nest cavity by two or more conspecifics," and Krysko et al (2003, *op. cit.*) amended this definition to include "the non-incidental deposition of eggs by geckos of different genera." On the other hand, not all egg aggregations should be interpreted as communal nesting, because large aggregations of gecko eggs may also represent the repeated use by a single female or a combination of both (Bock 1996. Herpetol. Rev. 27:181–183). To our knowledge, this behavior has only been verified in *Phyllopezus pollicaris* among South American phyllodactylids (Righi et al., *op. cit.*; Vitt, *op. cit.*).

Funding and field support were provided by National Science Foundation (NSF). JC is granted by Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP). We thank Renato S. Recoder, Mauro Teixeira-Jr, Agustín Camacho, Renata C. Amaro, Roberta P. Damasceno, Ana C. Carnaval, and Craig Moritz for field assistance, and Vanessa K. Verdade for critical reading of the manuscript. We also thank Jackson D. Shedd for review and editorial suggestions.

PHELSUMA LATICAUDA **(**Gold Dust Day Gecko**). PREY.** The diurnal geckos of the genus *Phelsuma* of Madagascar are sit-and-wait predators (Ikeuchi et al. 2005. Amphibia-Reptilia 26:475–483). Geckos of this genus have varied diets, but are mainly insectivorous (Ikeuchi et al. 2005, *op. cit.). Phelsuma laticauda*

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Gold Dust Day Gecko (*Phelsuma laticauda*) attempting to feed on a Stump-toed Gecko (*Gehyra mutilata*).

is widely distributed and abundant in the coastal northeast and Sambirano regions (Glaw and Vences 2007. A Field Guide to the Amphibians and Reptiles of Madagascar. 3rd ed. Cologne, Vences and Glaw Verlag. 496 pp.).

On 7 August 2009 at 1315 h on the office door of World Wide Fund for Nature (WWF) in Andapa (14.660°S, 49.650°E), Sava Region, northeastern Madagascar, I found an adult *P. laticauda* attempting to feed on a juvenile Stump-toed Gecko (*Gehyra mutilata*) (Fig. 1). The *Gehyra* had been bitten and was being held by the head with its hind limbs and tail curled towards the *Phelsuma*'s mouth. As I approached to take a closer photo of this predatory prey interaction, the *Phelsuma* released its hold on the *Gehyra* gecko. The *Gehyra* gecko was fatigued and extremely weak, but still had the ability to crawl into a narrow refuge between planks in the office floor where the *Phelsuma* could not follow it. Because of its age, the nocturnal juvenile prey species may have less diurnal hiding experience and may have been detected by the *Phelsuma*. I believe this is the first recorded observation of a predation attempt by a *P. laticauda* on a relatively large prey item *G. mutilata*, or any other vertebrate. The foraging behavior of *Phelsuma* species may change greatly according to prey abundance and distribution, as suggested by Ikeuchi et al. 2005 (*op. cit.*).

I thank Miguel Vences and Akira Mori for their helpful comments on an earlier version of this note. I thank M. Henri Raoeliarimalala for his assistance during this observation and Russell Thorstrom for help with the submission process.

PHRYNOSOMA MODESTUM (Round-tailed Horned Lizard). **PREDATION AND NESTING.** While I was studying nesting behavior of *Phrynosoma modestum*, a gravid female of this species (SVL 50 mm, mass 8.2 g) was followed daily by radio-telemetry (Holohil™ BD-2, 1.5 g transmitter/ Telonix™ TR-4 receiver with Telonix™ Model RA-14K antenna). The female had been collected in Hidalgo Co., New Mexico, USA (31.9671167°N, 108.6207667°W, datum WGS 84) 25) in May 2009 and released 27 June at the study site (31.9121667°N, 109.08765°W) in Cochise Co., Arizona (Chihuahuan Desert shrub/grassland vegetation; Brown et al. 1997. Proc. Natl. Acad. Sci. USA 94:9729–9733). On 10 July (0830 h), while searching for the female lizard I encountered an adult *Masticophis flagellum lineatulus* (SVL 116 cm, TL 35 cm; mass 280 g) and captured it by hand. *M. flagellum* is known to predate other larger species of horned lizards (see references in Sherbrooke 2008. J. Herpetol. 42:145–152; Sherbrooke and May 2008. Herpetol. Rev. 39:156–162), but has not been reported to prey on *P. modestum*. While holding the snake, I continued the search for the lizard and soon found myself turning in circles attempting to locate the direction of the transmitted signal from the lizard. Refocusing my efforts, I noted that the transmitter signal was coming from the snake, still in my hand. There was no obvious bulge in the snake's body but my conclusion was that the snake had recently eaten the lizard. During my initial search for the lizard, just prior to seeing the snake, I had noted a freshly excavated hole in the soil (with an adjacent pile of loose soil) that appeared to be the result of lizard nest-digging. The horizontal-elliptical opening was the size of the round-tailed horned lizard and deep enough to accommodate its body, but it had not been fully excavated (only about 2 cm deep) and was without eggs. This suggests that the female's nest-digging activities might have attracted the snake, and that lizards are vulnerable to predation during diurnal-nesting activities. Other horned lizards were concurrently nesting at the same site. A larger female *P. modestum* (SVL 63 mm; 14.7 g), also being followed in the same study, had nested on 4 July (nest covered by late morning; a previously observed *P. modestum* nested nocturnally at the same location, Sherbrooke 2000. Herpetol. Rev. 31:242–243), and several (N = 7) *Phrynosoma cornutum* nested here between 27 June and 11 July 2009. Rain fell at the site on 25, 26, and 28 June, and 2, 3, 4 and 5 July, 2009. The snake was subsequently held in captivity and the radio-transmitter was recovered, having passed its digestive tract by 20 July 2009.

PODARCIS PITYUSENSIS (Ibiza Wall Lizard). **DEATH-FEIGNING BEHAVIOR**. Many animals display thanatosis, or death-feigning behavior, as an anti-predatory mechanism (Arduino and Gould 1984. Anim. Behav. 32: 921–923; Sargent and Eberhardt 1975. Am. Midl. Nat. 94:108–109; Sazima 1974. J. Herpetol. 8:376–378), and while thanatosis has been widely documented in snakes (Gehlbach 1970. Herpetologica. 26:24–34) this behavior is much less common among lizards (Gallup 1973. Copeia 1973:623–624). Here, I present evidence that the *Podarcis pityusensis* feigns death after being held on its back for two to five seconds. Once this behavior has initiated, the lizard can be clapped at without moving—in some cases for an excess of five minutes. However, if one walks away from the lizard for more than a few seconds, the lizard quickly rolls over and attempts to escape.

Podarcis pityusensis is a diurnal, ground dwelling lizard endemic to Ibiza and Formentera (and nearby rocky islets) in the Balearic Island chain off the coast of Spain (Cirer and Martinez-Rica 1990. Herpetol J. 1:465–473; Martinez and Cirer 1982. Biol. Cons. 22:295–314). A host of animals prey on *P. pityusensis* including birds, snakes, and mammals (Alcover 1984. Saügetierkundliche Mitteilungen 31:189–195; Carretero 2004. Ital. J. Zool. 2:121–133; Pérez–Mellado 1988. Fauna Ibérica. 10:294–302).

Using a noose, I collected 96 *P. pityusensis* from five different populations. I captured 20 lizards from each of the following sites within the Balearic Islands: 1) Tagomago (39.037°N, 1.645°E), 2) Ses Salinas (38.822°N, 1.411°E), and (3) Mirador des Savinar (38.871°N, 1.411°E) on Ibiza, 4) the islet s'Espalmador (38.784°N, 1.425°E), and 16 lizards from 5) Es Trocadors (38.766°N, 1.435°E) on Formentera. All lizards were brought into a nearby tent, where I measured coloration on various parts of their body using a spectrophotometer and then photographed their backs, sides, and stomachs. Naturally, the lizards continuously attempted to escape by squirming, biting, and defecating; however, when I placed them on their backs, gently holding them down for two to five seconds in order to photograph their bellies, the lizards went limp, relaxing their limbs, head, and tail, curling their toes, and in many cases continued to defecate. Further, some lizards would arch their heads back, leaving their mouth slightly agape. Lizards initiated this behavior only after several seconds of being overpowered and while I quantified this behavior by placing lizards on their back, many lizards also initiated this defense strategy when they were overpowered right-side-up. Of the 96 lizards photographed, 74 initiated thanatosis when they were first held on their backs. The remaining 22 lizards displayed this behavior on the second or third try. Once limp, clapping my hands close to the lizards did not elicit any reaction. In fact, the only movement I observed during this behavior was their breathing and defecating. Once thanatosis initiated, 84 lizards remained in this position until I walked ca. 2 m away, at which time the majority of them promptly turned over and tried to escape. 41 of these 84 lizards remained in thanatosis for over two minutes, and in three cases, lizards remained on their backs for an excess of five minutes, turning over only when I gently poked their belly with my index finger. The remaining 12 lizards remained limp on their backs for 20 seconds or less, trying to escape before I walked away from them.

Although the adaptive significance of this behavior is not investigated here, presumably this behavior is an anti-predatory adaptation intended to confuse predators that have managed to catch a lizard (Gehlbach 1970, *op. cit.*; Pasteur 1982. Ann. Rev. Ecol. Syst. 13:169–199). This is a risky strategy, as lacertid lizard bellies are one of the softest parts of their body (pers. obs.); however, from my observations, it is a strategy that they adopt only after being overpowered—perhaps a strategy of last resort.

Patterns of thanatosis in other taxa suggest that individuals who exhibit death-feigning behavior maximize their probability of survival even after being captured. For example, Sargent and Eberhardt (1975, *op. cit.*) found that ducks who feigned death in response to being captured by red foxes increased the likelihood of their survival when compared with ducks that did not feign death because staying still seemed to minimize further attacks. It seems reasonable that death feigning in lizards could similarly affect their predators and increase the likelihood of a lizard's survival after capture. By going limp, a lizard might convince a predator that it is dead and, as a result be left alone long enough to escape. In conjunction with the visual immobility tactic, I observed that most of the lizards defecated before or during their death feigning response. Various other animals combine visual and olfactory cues to deter predators. For example, Doody et al. (1996. Herpetol. Rev. 27:82–83) found that the Mud Snake (*Farancia abacura*) defecates during or just before playing dead. Using both strategies together might maximize an individual's likelihood of survival.

It is well known among experienced herpetologists and pet keepers that many lizards seem to relax when they are turned on their backs. This behavior, referred to as tonic immobility or animal hypnosis, is characterized by a state of intense unresponsiveness and apparent temporary paralysis produced by a form of physical restraint (Gallup 1973, op. cit.). However, I believe that the death-feigning behavior exhibited by *P. pityusensis* is distinct from this commonly observed "relaxing" behavior. First, as defecation is an anti-predatory behavior used across many taxa, its employment in conjunction with putative death-feigning suggests that the strategy displayed in *P. pityusensis* is in fact an anti-predatory behavior. Additionally, the lizards in this study seemed to gather environmental cues to determine the duration with which they remained immobile. The duration of thanatosis in *P. pityusensis* was affected by how close I was to the lizards. As I moved farther away, lizards were more likely to terminate death-feigning and attempted to escape. Similar reports have been described of the recovery time from immobility in juvenile Eastern Hognose Snakes (*Heterodon platirhinos;* Burghardt and Greene 1988. Anim. Behav. 36:1842–1844) and the Green Anole (*Anolis carolinensis*; Gallup 1973, *op. cit.*). Finally, some lizards arched their heads back and opened their mouth during this behavior. Snakes that display thanatosis, such as *H. platirhinos,* also lie on their backs with their mouth open (Burghardt and Greene 1988, *op. cit.*). Although *P. pityusensis* do not leave their tongues protruding like snakes do, this open mouth display has not been described in other lizards that that exhibit tonic immobility. Together, these observations strongly suggest that the visual immobility displayed by *P. pityusensis* should be categorized as thanatosis, making this one of the first documented cases of lizards employing this behavior.

This may be a strategy common in other, closely related lizards (Gallup 1973, *op. cit.*). Future research should investigate the presence of this behavior in related lizard species and interperet its adaptive significance. Predator diversity among different populations living on various islands within this chain has not been quantified, however, differences in predation pressure is suggested in the striking color variation observed among populations of *P. pityusensis* with cryptic lizards representing some populations and conspicuously colored in others (Cirer and Martinez-Rica 1990, *op. cit.*; Dappen, unpubl. data). Moreover, predator regimes have been found to vary dramatically among Northern Balearic Islands, and these differences have affected other aspects of anti-predatory behavior in lizard populations such as the employment of caudal autonomy, or the minimum distance to which these lizards will allow potential predators to approach them before es-

caping (Pafilis et al. 2007. Naturwissenschaften 7:320–325). As I observed variation in both the initiation and duration of thanatosis in *P. pityusensis*, a logical next step would be to investigate the employment of this behavior among populations of lizards that are exposed to varying degrees of predation pressure.

Many thanks to the Balearic Park Service for transportation to and from various islands and permission to work with these lizards (Permit #Exp: 513/2009). I thank Matthias Kuhn for allowing me access to his private island and Jochen Krieg for transportation to and from Tagomago. Also, thanks to Sara D'Anzeo, Neil Losin,Yoel Stuart, and Jackson Shedd for help in improving the quality of this note. Lastly, I thank Valentin Perez-Mellado for helping introduce me to this species.

XENOSAURUS PHALAROANTHEREON (Chin-spotted Knob-scaled Lizard). **LITTER SIZE.** All species in the lizard genus *Xenosaurus* are viviparous (Ballinger et al. 2000. Cat. Amer. Amphib. Rept. 712:1–3). Our understanding of reproduction and reproductive variation among species and populations of *Xenosaurus* has been increasing recently, however our knowledge of reproductive traits (e.g., litter size, age at maturity, etc.) of each species is frequently limited and based on only one or two populations of each species. Here we report on the litter size of a population of *X. phalaroanthereon*, a recently described species (Nieto-Montes de Oca et al. 2001. Herpetologica 57:32–47) from Oaxaca, Mexico. Some basic information on the reproduction of *X. phalaroanthereon* has been published, but has been limited to observations on age at maturity (Lemos-Espinal and Smith 2005. Phyllomedusa 4:133–137) and limited observations of litter size and relative litter mass (Zamora-Abrego et al. 2007. J. Herpetol. 41:630–637).

We examined specimens of *X. phalaroanthereon* from the collection of the Laboratorio de Ecología, UBIPRO – FES-Iztacalal UNAM (N = 26). These specimens were collected from the vicinity of Santa Maria Ecatepec, Oaxaca, Mexico (16.245444°N, 95.960722°W, datum WGS84; 2185 m elev.) (see Lemos-Espinal and Smith 2005, *op. cit.* for description of the general area). We measured SVL for each specimen. We then dissected lizards to obtain information on litter size based on the presence of embryos.

Mean litter size was 2.00 ± 0.36 (N = 6). There was a marginally significant trend for litter size to decrease with increasing SVL (N = 6, r^2 = 0.60, P = 0.07; LS = 26.5 – 2.1 SVL). This litter size is slightly smaller than that reported for a small sample of *X. phalaroanthereon* (2.34) in Zamora-Abrego et al. (2007, *op. cit.*). The litter size reported here is among the smallest reported for any *Xenosaurus* (e.g., Ballinger et al. 2000. Stud. Neotrop. Fauna Environ. 35:179–183; Lemos-Espinal and Rojas-González 2000. Herpetol. Rev. 31:153; Lemos-Espinal et al. 2003. J. Herpetol. 37:192–196; Lemos-Espinal et al. 2004. Amphibia-Reptilia 25:204–210; Zamora-Abrego et al. 2007, *op cit.*; Rojas-González et al. 2008. J. Herpetol. 42:332–336). The influence of female SVL on litter size in *Xenosaurus* appears to be variable, with some populations and species showing a positive relationship (e.g., Ballinger et al. 2000, *op. cit.*; Rojas-González et al. 2008, *op. cit.*) and others showing no relationship (e.g., Ballinger et al. 2000, *op. cit.*; Lemos-Espinal et al. 2004, *op. cit.*). However, no previous study has found a negative relationship.

XENOSAURUS PHALAROANTHEREON (Chin-spotted Knob-scaled Lizard). **DIET.** Lizards in the genus *Xenosaurus* appear to be opportunistic foragers, with diets that can include a variety of prey, such as arthropods and vertebrates, but consist primarily of insects (e.g., Ballinger et al. 1995. Biotropica 27:128–132; García-Vázquez et al. 2009. Herpetol. Rev. 40:93; Lemos-Espinal et al. 2003. Southwest. Nat. 48:119–122; Lemos-Espinal et al. 2004. Amphibia-Reptilia 25:204–210; Presch 1981. Herpetol. Rev. 12:81). Our knowledge of the ecology of *Xenosaurus* has rapidly increased in the past 10 years, however our knowledge of individual species is still relatively limited, and frequently confined to one or two populations for each species. For some species, we still know very little about their diet. Here we report on the diet of a population of the fairly recently described *X. phalaroanthereon* (Nieto-Montes de Oca et al. 2001. Herpetologica 57:32–47) from Oaxaca, Mexico. Information on the ecology and biology of *X. phalaroanthereon* is limited to aspects of its thermal biology, microhabitat use, sex ratio, age at maturity (Lemos-Espinal and Smith 2005. Phyllomedusa 4:133–137), some aspects of its reproduction based on a small sample (Zamora-Abrego et al. 2007. J. Herpetol. 41:630–637), and a note on its consumption of a mammal (García-Vázquez et al. 2009, *op. cit.*).

We examined specimens of *X. phalaroanthereon* from the collection of the Laboratorio de Ecología, UBIPRO – FES-Iztacalal UNAM (N = 26). These specimens were collected from the vicinity of Santa Maria Ecatepec, Oaxaca, Mexico (16.245444°N, 95.960722°W, datum WGS84; 2185 m elev.) (see Lemos-Espinal and Smith 2005, *op. cit.* for description of the general area). We dissected lizards to obtain information on diets. We identified each prey item to order or family as possible, and measured the length and width of each item using an electronic caliper (to nearest 0.1 mm). We estimated prey volume using the formula for a prolate spheroid.

Of the 26 lizards examined, only 15 (58%) contained prey items. The diet of *X. phalaroanthereon* is summarized in Table 1. Numerically, the most important diet items were ants (Formicidae), and volumetrically the most important items were coleopterans. Ants and dipteran larvae were found in the most stomachs. This diet is similar to previous reports on the diets of *Xenosaurus* that have found that they consume primarily insects (Ballinger et al. 1995, *op. cit.*; Lemos-Espinal et al. 2003, *op. cit.*; Lemos-Espinal et al. 2004, *op. cit.*). We found no evidence of vertebrates in the

SQUAMATA — SNAKES

AGKISTRODON PISCIVORUS (Cottonmouth). **INTERSEXUAL COMBAT.** Male-male combat has been thoroughly described in many snake species, and is recognized as a form of competition for access to mates (Carpenter and Gillingham 1990. *In* Gloyd and Conant [eds.], Snakes of the *Agkistrodon* Complex, pp. 523–531. Contributions in Herpetology, No. 6, SSAR, Oxford, Ohio.). Combat behavior between males and females has never been described in nature, although reports of intersexual combat have been described from adders kept in semi-natural outdoor enclosures (e.g., *Vipera berus*—Kelleway 1982. Brit. J. Herpetol. 5:225–230). The sequence of behaviors listed in Table 1 occurred between an adult male (SVL = 64 cm; 265 g) and adult female (SVL = 60 cm; 220 g) *Agkistrodon piscivorus*, and was observed while conducting long-term, mark-recapture research on a population in Alabama, USA (Tuskegee National Forest, Macon County; 32.430613°N, 85.647406°W, WGS84) on 03 May 2007 (ca. 1845 h). Both snakes were sexed (by probing) and had been previously marked (PIT tagged). Their sex had been identified consistently during previous captures. Both snakes were of mature body size (Gloyd and Conant 1990, *op. cit.*). After processing, both snakes were released at their point of capture.

The behavioral sequence described in Table 1 is nearly identical to that of male-male combat in snakes (Gillingham 1987. *In* Seigel et al. [eds.], Snakes: Ecology and Evolutionary Biology, pp. 184–209. Macmillan Publ. Co., New York). We observed behaviors typical of combat (e.g., head, neck, and trunk raised from substrate, topping, apparent chasing and retreating; Table 1), yet few of the aspects typical of courtship (e.g., chin rubbing, mounting, tongue flicking the dorsal surface of female; components of the tactile chase and any component of the tail searching copulatory attempt). The chasing behavior observed is common to the late phase of combat and the early phase of courtship, although in our observation they were followed by vertical trunk raising and topping, not mounting. Head jerking by males is usually indicative of courtship, although males occasionally exhibit this behavior toward other males during the late phases of combat (G. W. Schuett, pers. comm.).

If the interaction described in Table 1 is interpreted as courtship, it suggests the courtship sequence in *A. piscivorus* (which has not been thoroughly described; Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Inst. Press, Washington D.C. 668 pp.) can be very different from that of other pitvipers and its congener, *A. contortrix* (Copperhead). This raises the possibility that earlier literature reports of ritualized "dances" in this species (e.g., Carr and Carr 1942. Proc. New England Zool. Club 20:1–6) could indeed be describing a component of courtship between males and females (which most authors have discounted—Lowe 1948. Herpetologica 4:129–135; Gillingham 1987, *op. cit.*). This could function as some sort of mate assessment by females (e.g., Schuett and Duvall 1996. Anim. Behav. 51: 367–373). It is also possible that *A. piscivorus* occasionally engage in intersexual combat, as reported in adders (Kelleway 1982, *op cit.*).

In *Vipera berus*, combat behavior outside the mating period includes intersexual combat and may represent competition for food (Kelleway 1982, *op. cit.*). Our observation took place much later in spring than the apparent spring mating season in *A. piscivorus* (i.e., March—Beyer 1898. Am. Nat. 32:17–24; Wharton 1966. Copeia 1966:149–161; Johnson et al. 1982. Herpetologica 38:16–25), and too early for the late summer/fall mating period (i.e., August-September—Zaidan et al. 2003. Copeia 2003:231–240; Graham et al. 2008. Gen. Comp. Endocrinol. 159:226–235). However, the mating season of *A. piscivorus* is equivocal (Graham et al. 2008, *op. cit.*), and combat behavior in *A. piscivorus* has been reported in March (Carr and Carr 1942, *op. cit.*), June (Ramsey 1948. Herpetologica 4:228), August (Hill and Beaupre 2008. Copeia 2008:105–114), and September (Martin 1984. Copeia 1984:772–774; Fogleman et al. 1986. Bull. Chicago Herpetol. Soc. 21:26–28). We suggest the possibility that combat sometimes occurs for motives other than mating in this species (see Blem 1987. J. Herpetol. 21:64–65), and that intersexual combat may sometimes occur in *A. piscivorus*.

We thank G. W. Schuett, C. Guyer, and J. C. Godwin for comments and helpful suggestions on this note. This observation was made while conducting research funded by NIH grant #R01-A149724 to T. Unnasch under ADCNR Permit #4268.

TABLE 1. Interaction sequence between a male and female *Agkistrodon piscivorus* from Tuskegee National Forest, Alabama, USA. Interpretations are based upon Gillingham (1987. *In* Seigel et al. [eds.], Snakes: Ecology and Evolutionary Biology, pp. 184–209. Macmillan, New York).

Time (CST)	Male behavior	Female behavior	Microhabitat	Distance between snakes	Interpretation
1845	swimming movements, similar to "craning-cruising," e.g., Savitsky, 1992. *In* Campbell and Brodie (eds.), Biology of the Pitvipers, pp. 347–369. Selva, Tyler, Texas.	in water, body submerged, head held at ca. 75º angle	beaver dam pool	4 m

ALSOPHIS SIBONIUS (NCN). **COPULATION.** *Alsophis sibonius* is a diurnal, actively foraging snake inhabiting the Commonwealth of Dominica, West Indies. The snake was formerly considered a subspecies of *A. antillensis* but was recently elevated to full species status (Hedges et al. 2009. Zootaxa 2067:1–28). In general, little is known about mating behavior for *Alsophis* (*sensu stricta* Hedges et al. 2009, *op.cit*.) and to our knowledge, no accounts for mating behavior exist for *A. sibonius* (Henderson and Powell *In press*. Natural History of West Indian Reptiles and Amphibians. University Press of Florida, Gainesville). Here we report a field observation of copulation for *A. sibonius* from the Caribbean side of Dominica.

At 1125 h on 27 April 2009, we discovered a mating pair of *A. sibonius* on the forest floor in the Batali River Valley (15.44999°N, 61.44223°W, datum: WGS84), ca. 550 m from the Caribbean Sea. The snakes were partially concealed by leaf litter and were thus captured for identification before realizing they were in coitus. The pair differed both in color and size (Fig. 1). The male (SVL = 563 mm; total length = 772 mm) was black with a double alternating series of white blotches anteriorly, which graded to solid black posteriorly. The female (SVL = 683 mm; total length = 859 mm) had a stub tail and exhibited the same dorsal pattern as the male but with a light brown ground color and tan blotches.

The pair remained in coitus while they were manipulated for photographs and measured. When released on the ground for brief periods, the female attempted to escape while dragging the smaller male behind her. After 20 minutes the snakes disengaged and moved apart. Throughout the observation period, the female exhibited a swollen body cavity ca. 5 cm anterior to the cloaca (Fig. 1). Timing of this copulation event is consistent with a 6 April report for *Alsophis manselli* (*sensu* Hedges et al. 2009, *op. cit.*) on Montserrat (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville, Florida. 720 pp.).

We thank Robert Henderson for advice and comments concerning this account. This observation was made while conducting *Iguana delicatissima* research on Dominica funded through the San Diego Zoo's Institute for Conservation Research.

BOA CONSTRICTOR OCCIDENTALIS (Argentine Boa). **DIET.** *Boa constrictor occidentalis* is the southernmost subspecies of *Boa constrictor* and is distributed from 33º–36º S. It is found in extreme climates in the semiarid plains of the Phytogeographic regions of Chaco, Monte, and Espinal of Argentina (Chiaraviglio et al. 1998. Gayana Zool. 62:83–85; Di Cola et al. 2008. Amphibia-Reptilia 29:299–310). In central-eastern San Juan Province, this subspecies occurs in Chaco Árido, an ecotonal region between the Chaco and Monte Phytogeographic regions (Acosta et al. 2000. Cuad. Herpetol. 14:163). In Argentina, *B. c. occidentalis* is considered a "threatened" species (Lavilla et al. 2000. Categorización de Anfibios y Reptiles de la República Argentina. Asoc. Argentina Herpetol. 79 pp.) due to hunting pressure and habitat loss related to human population growth and agricultural expansion. Sightings of this species in Argentina are uncommon and data on trophic ecology are limited.

On 15 December 2008, we observed a free-ranging adult *B.*

FIG. 1. *Boa constrictor occidentalis* consuming a *Chunga burmeisteri* in Sierra de Guayaguas, Argentina (photo by JM).

c. occidentalis (total length ca. 3 m) in Sierra de Guayaguas, 25 de Mayo Department, corresponding to the Chaco Árido Phytogeographic Region in Argentina (31.85°S, 67.17°W, datum WGS84; elev. 557 m). The snake was apparently in an ambush posture on the ground beneath the canopy of *Ximenia americana* (albaricoque) shrubs along a trail used by "walking birds" (*Chunga burmeisteri*; "chuña patas negras," Cariamidae). Later, a *C. burmeisteri* that was passing along the trail was caught by a fast strike from the snake and was subsequently constricted and ingested over the course of ca. 25 min (Fig. 1). *Boa constrictor* are opportunistic predators that are known to feed on a variety of mammals, birds, and lizards, and are sit-and-wait foragers (Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. of Chicago Press, Illinois, 934 pp.; Solorzano 2004. Snakes of Costa Rica. Instituto Nacional de Biodiversidad, Costa Rica, 791 pp.). This note constitutes a first record of predation on *C. burmesteri* by *B. c. occidentalis* and confirms that this snake uses ambush foraging to feed on "walking birds."

Submitted by **ALEJANDRO LASPIUR** (e-mail: laspiursaurus@gmail.com), **JUAN CARLOS ACOSTA, JUSTO MÁRQUEZ,** and **GRACIELA BLANCO,** Departamento de Biología, Facultad de Ciencias Exactas, Físicas y Naturales, Universidad Nacional de San Juan. Avenida Ignacio de la Roza 590 (N), Caixa Postal 5400, San Juan, Argentina.

BOTHROPS MOOJENI (Brazilian Lancehead). **DIET.** The pitviper *Bothrops moojeni* occurs throughout the Cerrado region of central and southeastern Brazil, mainly in open and forested riparian areas (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere, Vol. I. Cornell Univ. Press, Ithaca, New York. 475 pp.; Nogueira et al. 2003. J. Herpetol. 37:654–659). This terrestrial lancehead has a variable diet that includes mammals, frogs, lizards, snakes, birds and even centipedes, with adults preying more frequently on mammals (Nogueira et al. 2003, *op. cit.*). On 5 December 2008 at 1930 h, we captured an adult male *B. moojeni* (SVL = 958 mm) in a palm swamp ("vereda") site in Área de Proteção Ambiental do Rio Pandeiros (15.43ºS, 44.81º W, datum SAD1969), a conservation unit in municipality of Januária, north of Minas Gerais State, southeastern Brazil. After dissection, we found an adult *Leptodactylus fuscus* (SVL = 41.7 mm) in snake's stomach, that had been ingested head-first. *Leptodactylus fuscus* has been recorded in the diet of *B. moojeni* and *B. atrox*, an Amazonian lancehead closely related to *B. moojeni* (França et al. 2008. Copeia 2008:23–28; Macedo-Bernarde and Bernarde 2005. Herpetol. Rev. 36:456; Nogueira et al. 2003, *op. cit.*). This observation supports the hypothesis of diet similarity between these species and corroborates the idea that despite ontogenetic dietary shifts, adult *B. moojeni* do not eliminate small prey from their diets (Martins et al. 2002. *In* Schuett et al. [eds.], Biology of the Vipers, pp. 307–328. Eagle Mountain Publ., Eagle Moutain, Utah). Voucher specimens were deposited in the herpetological collection of Museu de Zoologia João Moojen, Universidade Federal de Viçosa, in Viçosa, Minas Gerais, Brazil (*B. moojeni*, MZUFV 1639; *L. fuscus* MZUFV 9258).

We thank Henrique Caldeira Costa for valuable comments on the manuscript, Conselho Nacional de Desenvolvimento Científico e Tecnológico for financial support through project MCT/CNPq/MMA/MI/CT-Hidro nº 035/2006, Instituto Estadual de Florestas for logistical support and Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA) for providing collecting permits (10504-1).

COLUBER CONSTRICTOR (North American Racer). **PULL-TAB ENTANGLEMENT.** Entanglement of reptiles and amphibians in human-made materials is increasingly evident (reviewed by Vann et al. 2005. Herpetol. Rev. 36:322; Dean et al. 2005. Herpetol. Rev. 36:179–180; Stuart et al. 2001. Herpetol. Rev. 32:162–164). Most previous reports have involved entanglement in plastic materials (but see Dean et al., *op. cit.;* Herrington 1985. Herpetol. Rev. 16:11). Here I report the first case of girdling of a snake by an aluminum pull-tab, apparently from a soft drink can.

On 5 July 2009, I discovered a male *Coluber constrictor* (total length = 121 cm) in a window well at my rural residence (Indiana, Wayne Co., USA, ca. 7 km WSW Richmond: 39.7978°N, 84.9658°W, datum: WGS84). Although it was typically robust and feisty, its torso was encircled by an aluminum pull-tab at a point ca. 30 cm from the tip of the snout (Fig. 1). The pull-tab was the removable kind used on soft drink cans in the USA between 1962 and 1975 (www.squidoo.com/canpulltab), but with only the circular ring left intact. Based on the apparent health of the snake and the evident (but not extensive) external damage to the snake, it must have been girdled for only a short time (estimated at 2–4 weeks). Upon removal of the pull-tab, the snake was released; it moved into a forest edge quickly with no apparent long-term locomotor damage. This observation demonstrates that although

FIG. 1. Aluminum pull-tab girdling a male *Coluber constrictor* from Wayne Co., Indiana, USA.

contemporary pull-tabs remain attached to drink cans, the older removable types remain a danger to wildlife, even in rural settings with minimal access to human refuse. Notably, this site was an agricultural field adjacent to a middle growth forest until 1997.

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). **NOXIOUS WEEDS AS A HAZARD TO SNAKES.** Invasive species and their deleterious effects on native species are well known (e.g., Cox 2004. Alien Species and Evolution. The Evolutionary Ecology of Exotic Plants, Animals, Microbes, and Interacting Native Species. Island Press, Washington DC. 377 pp.). However, the direct effects of noxious plants on native snakes have not been described. Here I report the presence of seed heads of an invasive species, the Longspine Sandbur Grass (*Cenchrus longispinus*), in the buccal cavity of a *Crotalus viridis viridis*.

While processing a rattlesnake from a den site in Weld Co., Colorado, USA, a tumor-like lump was observed in the floor of the mouth. After venom extraction and PIT-tagging, the mouth of the restrained snake was held open by an assistant, and a soft greyish mass approximately 12.5 x 22 x 10 mm was removed. This mass covered much of the rear buccal cavity, from ca. 5 mm posterior to the glottal opening to the back of the mouth. Upon cleaning the soft flocculent material from the surface of the harder core, two spiny seed heads (mature inflorescences) of the noxious grass *Cenchrus longispinus* were revealed (Fig. 1).

Cenchrus has long been recognized as a noxious invasive species in the western United States (California Department of Food and Agriculture Encycloweedia: Data Sheets - http://www.cdfa.ca.gov/phpps/ipc/weedinfo/cenchrus.htm). It has more recently become widespread in eastern Colorado, often in association with overgrazing and soil disturbance. Although we have occasionally found rattlesnakes in the field with plant spines (commonly the small spines of *Opuntia* sp.) imbedded in their skin, this is the first observation of a noxious weed causing internal injury to a snake. It is unclear how the seeds were ingested, but it is likely that they were consumed along with rodent prey and became lodged in the mouth. The nature of the soft grey matter covering the seed heads is unknown, but the end effect was to provide a soft surface over the spines of the seeds which were anchored to the floor of the mouth by embedded spines. The snake appeared to suffer no long-term ill effects of the embedded seed heads, but it is difficult to imagine that swallowed seed heads would remain benign. This observation underscores the fact that invasive species can affect native species in multiple ways; *Cenchrus* could lead to decreases in prey abundance as it displaces native grasses and its seed heads can directly impact snake foraging activities. Further, because this species appears to be increasing in abundance northward from a more subtropical distribution (Parker and Boydston 2008. Longspine Sandbur, *Cenchrus longispinus*. PNW Regional Extension Publication 0353. http://www.ars.usda.gov/research/publications/publications.htm?seq_no_115=231551), climate change may exacerbate its effects on snakes by favoring its establishment in more northern habitats such as northeastern Colorado and elsewhere across the plains states.

I thank R. Malecki for assistance with processing snakes, C. Rex for photography, and R. Loose for allowing access to his property.

DRYMOBIUS MARGARITIFERUS FISTULOSUS (Central American Speckled Racer). **DIET**. *Drymobius margaritiferus* is a terrestrial colubrid inhabiting lowland tropical and subtropical areas from southern Texas to Colombia (Campbell 1998. Amphibians and Reptiles of Northern Guatemala, the Yucatan, and Belize. Univ. Oklahoma Press, Norman. 212 pp.). As anurans are the most important prey of *D. margaritiferus* (86% of their diet), this species generally inhabits wet or moist habitats. Additionally, *D. maragritiferus* is most active during the wet season when amphibians are most active (Henderson and Hoevers 1977. Copeia 1977:349–355).

Between 1100 and 1300 h on 6 June 2008, we observed a *D.*

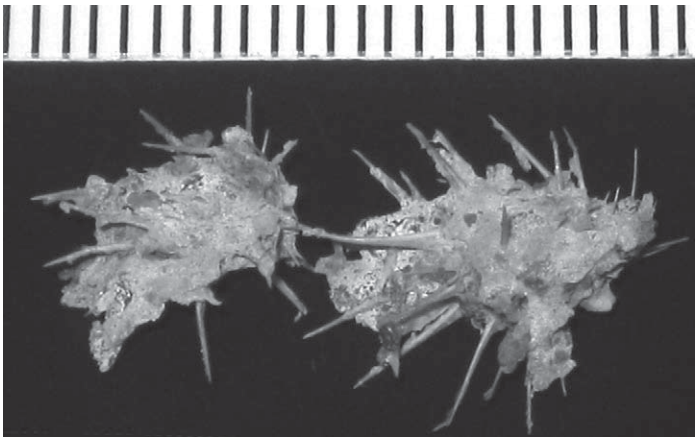

FIG. 1. Longspine Sandbur (*Cenchrus longispinus*) seed heads removed from the mouth of a *Crotalus viridis viridis* in Weld Co., Colorado, USA. Bars at top represent 1 mm gradations.

FIG. 1. A *Drymobius margaritiferus fistulosus* preying upon a *Hyla loquax* in Toledo District, Belize.

m. fistulosus consuming an anuran at the Aguacaliente Wildlife Sanctuary (16.1492667°N, 88.7718167°W, datum WGS84; elev. 15.2 m), Big Falls, Toledo District, Belize (Fig. 1). This event took place during the wet season about 38 m away from the nearest lagoon, viewed from a boardwalk, 1 m off the ground. Upon discovery, the frog's head was inside the mouth of the snake yet it still appeared alive. The snake was continuously biting the frog, a behavior executed by *D. m. fistulosus* to kill its prey (Werler and Dixon 2000. Texas Snakes. Univ. Texas Press, Tyler. 437 pp.). Although the head of the prey was not observed, examination of its feet and physical morphology identified the frog as *Hyla loquax* (Red-footed Treefrog). This observation represents the first documentation of *H. loquax* as a prey species for *D. m. fistulosus*.

Young Dr. S., Los Angeles, California 90095, USA (e-mail: marisa_tellez@sbcglobal.net); and **CHERIE CHENOT-ROSE,** American Crocodile Education Sanctuary, P.O. Box 108, Punta Gorda, Toledo, Belize (e-mail: cherie@americancrocodilesanctuary.org).

DRYMOBIUS MELANOTROPIS (Black Forest Racer) and ***DRYMOBIUS RHOMBIFER*** (Esmarald Racer). **ENDOPARASITES**. *Drymobius melanotropis* ranges from eastern Honduras through southeastern Costa Rica at 35–1000 m elevation. *Drymobius rhombifer* occurs from Nicaragua south through Central America, Colombia, Venezuela, and the Guianas, and much of the Amazon basin to southern Peru and northern Bolivia at 13–1200 m elevation (Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. Chicago Press, Chicago, Illinois. 934 pp.). To our knowledge, there are no reports of helminths from these snakes. The purpose of this note is to establish initial helminth lists for *D. melanotropis* and *D. rhombifer*.

Four *D. melanotropis* (SVLs = 850, 794, 572, 220 mm) and two *D. rhombifer* (SVLs = 543, 453 mm) from Costa Rica were examined: *D. melanotropis* LACM 150529–150532 (collected 1974, 1985, 1986); *D. rhombifer* LACM 150533, 150534 (collected 1964, 1972). A mid-ventral incision was made in the posterior third of the body cavity and the coelomic cavity was searched for helminths. Nematodes and acanthocephalans were cleared in lactophenol and identified from wet-mounts.

Found in both *D. melanotropis* and *D. rhombifer* were nematode larvae (*Porrocaecum* sp.) in cysts, and acanthocephalan larvae (oligacanthorhynchid cystacanths). Prevalence of infection (number hosts infected/number hosts examined x 100) for *D. melanotropis*: 25% each for both *Porrocaecum* sp. (N = 5 helminths) and acanthocephalan cystacanths (N = 10); prevalence for *D. rhombifer*: 50% each for both *Porrocaecum* sp. (N = 2) and acanthocephala cystacanth (N = 1). Helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland, USA as *D. melanotropis: Porrocaecum sp.* (USNPC 102145), acanthocephala cystacanth (USNPC 102146; *D. rhombifer*: *Porrocaecum* sp. (USNPC 102147), acanthocephala cystacanth (USNPC 102148).

Species of *Porrocaecum* are parasites of the intestines of birds; earthworms serve as intermediate hosts and small animals that consume earthworms may serve as paratenic (= transport) hosts (Anderson 2000. Nematode Parasites of Vertebrates. Their Development and Transmission. 2nd ed. CABI Publishing, Oxon, UK. 650 pp.). Because the larvae occurred in cysts, we believe these snakes serve as transport hosts. Acanthocephalans require an arthropod intermediate host in which the cystacanth stage develops (Kennedy 2006. Ecology of the Acanthocephala. Cambridge University Press, Cambridge, UK. 249 pp.). Again, because the cystacanths occurred in cysts, snakes likely serve as paratenic hosts. Larvae of *Porrocaecum* and oligacanthorhynchid cystacanths are common in Central American snakes (Goldberg and Bursey 2004. Carib. J. Sci. 40:62–69) and have both been reported in the congener *D. margaritiferus* from Costa Rica (Goldberg and Bursey 2005. Texas J. Sci. 57:103–106). *Drymobius melanotropis* and *D. rhombifer* represent new host records for both larvae of *Porrocaecum* and oligacanthorhynchid cystacanths.

We thank C. Thacker (LACM) for permission to examine snakes which are part of the CRE (= Costa Rica Expeditions Collection) donated to LACM by J.M. Savage in 1998.

HETERODON PLATIRHINOS (Eastern Hog-nosed Snake). **OVIPOSITION**. Snake oviposition in the wild is seldom observed or described. In *Heterodon platirhinos*, nesting behavior was recently reported from four nests at the northern limits of the species' distribution (Cunnington and Cebek 2005. Am. Midl. Nat. 154:474–478). We observed nesting, nest chamber configuration, and clutch success after captive incubation for an *H. platirhinos* from Bryan, Brazos Co., Texas, USA. The female was first observed on 9 June 2007 at 1000 h at the entrance to a hole using her snout to push dirt out using side to side head movements. The hole began at 4 cm diameter in sandy loam, achieving 5 cm x 4.5 cm by the morning of 10 June 2007. Depth was unknown at that time. The female exited the nest at 1600 h on 13 June 2007, moving to shelter beneath a piece of tin 6.1 cm from the entrance. The entrance hole was completely refilled and was not apparent to the casual observer at that time. The female exited the site early on the morning of 12 June 2007. On 15 June 2007 the nest was excavated (Fig. 1) and found to contain 13 eggs. Eggs were found at depths ranging from 5 cm deep closest to the entrance to 12.7 cm deep 43 cm from the entrance hole. The eggs were incubated in vermiculite at 27.7°C in a Brinsea Octagon 20 (Brinsea Products Inc., Titusville, Florida, USA). After 65 days, on 14 Aug 2007, slits were observed in all but one of the eggs (92% hatch success). By 16 Aug 2007 the clutch had emerged and hatchlings were measured on 24 Aug 2007 after all had completed post-emergence ecdysis. The clutch means were 232.6 mm SVL, 40.3 mm tail length and 17.3 g. The sex ratio was 5M:7F; 8 of 12 (67%) were red in color with the remainder predominantly tan. All snakes were subsequently released at the nest site.

Our observations are in agreement with those of Cunnington

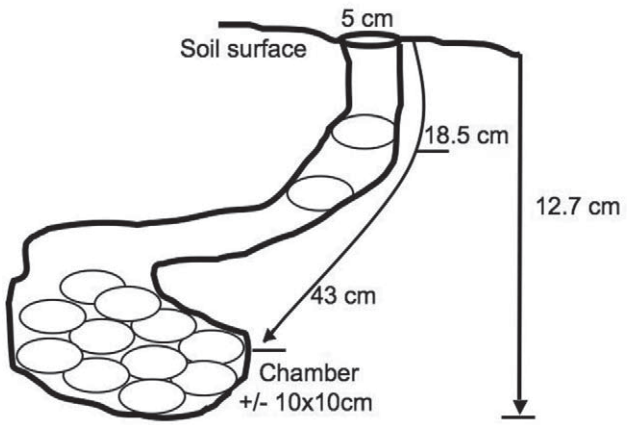

FIG. 1. *Heterodon platirhinos* nest cavity details after oviposition in central Texas, USA.

and Cebek (2005) with their report of 2–4 days for nest excavation to a depth of 10–15 cm. Our hatching success was higher (92%) than any Cunnington and Cebek (2005) reported from the wild (33–74%) or captivity (85%). As expected, our nesting dates were nearly one month earlier than their observations and, interestingly, our incubation times agree with two of their wild clutches, despite the dramatic difference in latitude between the sites.

Submitted by **MICHAEL R. J. FORSTNER,** Texas State University, Department of Biology, San Marcos, Texas 78666, USA (e-mail: mf@txstate.edu); and **JAMES R. DIXON**, Texas Cooperative Wildlife Collection, Texas A&M University, College Station, Texas 77843, USA.

HETERODON PLATIRHINOS (Eastern Hog-nosed Snake). **PREDATOR/PREY MASS RATIO**. Snakes are renowned for their ability to consume large prey relative to their body size. However, a recent review indicated that reported anuran prey items were always smaller than the snake predator (Toledo et al. 2007. J. Zool. 271:170–177). Herein we report two observations in which prey mass was greater than predator mass.

On 26 May 2009, we captured a *Heterodon platirhinos* within a box trap (Burgdorf et al. 2005. Herpetol. Rev. 36:421–424) on Eglin Air Force Base, Okaloosa Co., Florida, USA, that regurgitated a live 36 g *Scaphiopus holbrookii* (Eastern Spadefoot), despite attempts by us to minimize disturbance. Several days after this event, the *H. platirhinos* weighed 34 g, yielding a prey/predator mass ratio of 1.06. On 24 September 2008, we captured a 6 g *H. platirhinos* along a drift fence at Fort Benning, Chattahoochee Co., Georgia, USA. This snake regurgitated an 8 g *Anaxyrus terrestris* (Southern Toad; AUM 34804), a prey/predator mass ratio of 1.33. Although colubrid snakes may often consume large prey relative to their body size, they rarely take prey larger than themselves; the predator/prey mass ratios presented here are considerable.

LAMPROPELTIS CALLIGASTER CALLIGASTER (Prairie Kingsnake). **THERMAL ECOLOGY.** Although the thermal ecology of some species of snakes has been studied, the thermal ecology of many more snake species has not. Kapfer et al. (2008. J. Therm. Biol. 33:174–179) attributed this lack of emphasis on thermal ecology to the decline in the number of publications reporting natural history or field-based research on herpetofauna. The thermal ecology of snake species deserves more attention because maintenance of body temperature is important for the ecology and fitness of snakes (Blouin-Demers and Weatherhead 2008. Isr. J. Ecol. Evol. 54:361–372). My main objective was to investigate diurnal variation in body temperature of *Lampropeltis calligaster calligaster* associated with sex of the snake, month of sampling, and behavior.

Temperature-sensitive transmitters (Models SB-2T and SI-2T; Holohil Systems Ltd., Carp, Ontario, Canada) were surgically implanted by veterinarians (after Reinert and Cundall 1982. Copeia 1982:702–705; Blouin-Demers and Weatherhead 2001. Ecology 82:2882–2896), into six male and four female *L. c. calligaster* caught at Jim Edgar Panther Creek (JEPC) State Fish and Wildlife Area, in Cass Co., Illinois, USA (40.01°N, 90.04°W, datum WGS84). Snakes emerged from hibernation in late March and entered hibernation mid-October (Richardson et al. 2006. J. Herpetol. 40:423–428), so I tracked snakes for periods ranging from 14 to 193 d (mean = 120 d) from 10 May to 16 October 2004 and 29 March to 3 May 2005 to complete one annual activity cycle. I located each snake every 2 d between 0550 and 2022 h to incorporate variation in diurnal body temperature. Upon locating a snake, I recorded its body temperature and behavior (i.e., exposed aboveground, under cover aboveground, or underground). Means throughout are reported ± 1 SE.

I measured the body temperature of snakes 526 times from

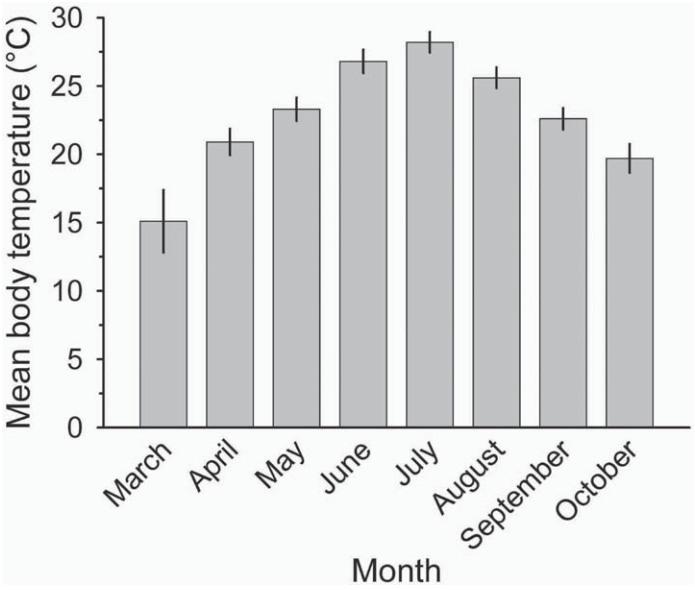

FIG. 1. Mean monthly body temperature (± 1 SE) of radio-tracked *Lampropeltis calligaster* from Cass County, Illinois, USA.

2004 to 2005. Females had a mean body temperature nearly two degrees higher than males across the active season (23.6 ± 0.67°C vs. 21.9 ± 0.63°C, respectively). Gravid females of other snake species often have higher body temperatures than males, but non-gravid females also may have higher body temperatures that promote rapid growth and ultimately achieve earlier reproductive maturity or larger clutch sizes (Blouin-Demers and Weatherhead 2008. Isr. J. Ecol. Evol. 54:361–372). The mean body temperature of both sexes combined increased from March through July and then steadily declined through October when snakes entered hibernation (Fig. 1), which may be influenced by ambient temperatures at the field site. The mean body temperature of snakes was similar aboveground, regardless of whether snakes were exposed or under cover (24.4 ± 0.86°C; 23.5 ± 0.79°C, respectively), indicating that snakes can thermoregulate under cover while being concealed from predators. However, body temperature of snakes was several degrees lower when snakes were underground (20.4 ± 0.55°C).

I thank P. J. Weatherhead and J. D. Brawn for their advice, G. Brummet and M. Allender for performing snake surgeries, and D. Skinner, Z. Stahlschmidt, and L. A. Kammin for assistance with fieldwork. Research was funded by a grant from the Illinois Department of Natural Resources to J. D. Brawn (Federal Aid Project Number W-136-R-04 to 05). The research protocol was approved by the Institutional Animal Care and Use Committee at UIUC.

LEPTODEIRA MACULATA (Southwestern Cat-eyed Snake). **DIET.** *Leptodeira maculata* occurs in the Pacific coastal lowlands and adjacent slopes of the Sierra Madre Occidental, Mexico, from southern Sinaloa southeastward to the Rio Balsas, and inland in the Balsas Basin in Michoacán and Guerrero to elevations of ca. 2000 m (Duellman 1958. Bull. Am. Mus. Nat. Hist. 114:1–151). Although little is known about the diet of this species, it is presumed to feed primarily on amphibians. Known prey taxa include *Bufo* (= *Incilius*) *mazatlanensis*, *Hypopachus oxyrrhinus*, and *Smilisca baudinii* (Duellman 1961. Univ. Kansas Publ. Mus. Nat. Hist. 15:1–148; Duellman and Trueb 1966. Univ. Kansas Publ. Mus. Nat. Hist. 17:281–375; Hardy and McDiarmid 1969. Univ. Kansas Publ. Mus. Nat. Hist.18:39–252). Here we report a novel prey species for *Leptodeira maculata*, *Lithobates neovolcanica* (Transverse Volcanic Leopard Frog), a ranid frog that is found in the states of Jalisco, Guanajuato, and Michoacán, Mexico (Hillis and Frost 1985. Occas. Pap. Nat. Hist. Mus. Univ. Kansas 117:1–14).

On 16 November 2008, we discovered a *L. maculata* while conducting a survey of the herpetofauna in the largest mangrove forest in Mexico, "Marismas Nacionales," in the state of Nayarit. While traveling between San Vicente-Unión de Corrientes, near "Los Espejos" ranch, Municipality of Tuxpan (21.9955556°N, 105.4386111°W, datum NAD27), a loud calling sound attracted our attention to a pond on the side of the road. Upon closer examination, we observed a *L. maculata* (total length ca. 70 cm) preying upon an adult *L. neovolcanica*. The animals were neither disturbed, nor collected.

P. 66450, México.

LEPTOTYPHLOPS GOUDOTII (Black Blind Snake). **UNUSUAL MICROHABITAT.** *Leptotyphlops goudotii* is a small fossorial snake distributed along the Mexican Pacific coastal and foothill regions of Colima, Michoacán, Guerrero, and Oaxaca, and slopes of the Gulf of Mexico from Tamaulipas and Veracruz, México, southward to Central America, Colombia and Venezuela (modified from McDiarmid et al. 1999. Snake Species of the World, a Taxonomic and Geographic Reference. Vol. 1. Herpetologists' League, Washington, DC. 511 pp.). Here, we report a specimen of *L. goudotii* collected from a microhabitat that is atypical for the species.

On 20 April 2002, we collected a specimen of *L. goudotii* in Punta Delgada, Municipality of Alto Lucero de Gutierrez Barrios, Veracruz, México (19.5129°N, 96.2732°W, datum WGS 84; elev. 2 m). The location was a rocky area of beach by the seashore. We believe the specimen reached the area by means other than overland dispersal; probably it was washed up on shore, because the species is typically found in vegetative debris, or under logs or rocks (Pérez-Higareda et al. 2007. Serpientes de la Región de Los Tuxtlas, Veracruz, México: Guía de Identificación. Instituto de Biología, UNAM), but not by the seashore. The specimen was deposited in the herpetological collection of Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo (CH CIB 0410).

Submitted by **JUDITH T. PAMPA-RAMÍREZ**, Centro Universitario de Ciencias Biológicas y Agropecuarias, Carretera a Nogales Km. 15.5 Las Agujas, Nextipac, Zapopan, Jalisco, México (e-mail: judithpampa@gmail.com); and **IRENE GOYENECHEA,** Centro de Investigaciones Biológicas (CIB), Universidad Autónoma del Estado de Hidalgo, A.P. 1-69 Plaza Juárez, Pachuca, Hidalgo, México (e-mail: ireneg@uaeh.edu.mx).

LIOPHIS POECILOGYRUS (Yellow-bellied Liophis). **DIET.** *Liophis poecilogyrus* is distributed across the South American continent and preys on a wide variety of animals, including anurans, lizards, fishes, insects, and rodents (Michaud and Dixon 1989. Herpetol. Rev. 20:39–41). Here I report an observation of *L. poecilogyrus* feeding upon two additional anuran species, *Leptodactylus bufonius* and *Physalaemus biligonigerus.*

At 2315 h on 15 March 2009 and at 2155 h on 20 March 2009, two *L. poecilogyrus* (SVL = 604 mm; tail length = 94 mm; 75 g post prey removal and SVL = 536 mm; tail length = 98 mm; 93 g post prey removal, respectively) were captured in a temporary pool in the Isoceño community of Yapiroa, Provincia Cordilleria, Departmento Santa Cruz, Bolivia (19.6000°S, 62.5667°W, datum

WGS84). The stomach contents of both snakes were checked by forced regurgitation. The snake captured on 15 March contained the posterior portion of a *L. bufonius*) and the individual captured on 20 March had a *P. biligonigerus* in its stomach. Both snakes were released the night following their capture.

As with *L. poecilogyrus*, both *L. bufonius* and *P. biligonigerus* are associated with temporary pools in the Gran Chaco (Cei 1980. Monitore Zool. Ital. Monogr. 2:1–609; pers. obs.), however this is the first record of either of these species in the diet of *L. poecilogyrus*.

Funding for this research was provided by the Applied Biodiversity Science National Science Foundation Integrated Graduate Education and Research Traineeship doctoral program (NSF-IGERT Award #0654377) at Texas A&M University.

Submitted by **CHRISTOPHER M. SCHALK,** Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843-2258, USA; e-mail: cschalk@tamu.edu.

LIOPHIS VANZOLINII (NCN). **CLUTCH SIZE.** *Liophis vanzolinii*, a colubrid snake belonging to the *Liophis "anomalus"* complex (Nixon 1985. Copeia 1985:565–573), is distributed in the San Luis and Córdoba provinces of central-eastern Argentina. This species occurs in mid-elevation mountain ranges, where grassy and rocky streams are common. No reproductive data exist for *L. vanzolinii* (Cei 1993. Reptiles del Noroeste, Nordeste y Este de la Argentina. Herpetofauna de las Selvas Subtropicales, Puna y Pampas. Museo Regionale di Scienze Naturali Torino. Monografie XIV. 944 pp.). Here we report the first data on clutch size for *L. vanzolinii*.

On 12 October 2008, we captured a gravid female (total length = 460 mm) *L. vanzolinii* at Estancia Las Verbenas, Valle de Pancanta (32.9°S, 66.1°W, datum WGS84; elev. 1650 m). The snake was maintained in a 120 x 60 x 40 cm terrarium with abundant leaves and gravel and it laid five eggs on 16 November 2008. The length and width of each egg were measured with Vernier calliper and the volume of each egg was calculated using the formula for volume of an ellipsoid sphere (Dunham 1983. *In* Huey et al. [eds.], Lizard Ecology, pp. 261–280. Harvard University Press, Cambridge, Massachusetts). The eggs averaged 30.8 mm (s = 1.17) in length; 14.7 mm. (s = 0.46) in width; and 4025.4 mm^3 (s = 404.7) in volume. Cei (*op. cit.*) reports clutch sizes of 6–15 for *L. anomalus* and *L. elegantissimus*, similar to more northerly *Liophis* species. Thus, typical clutch size for *L. vanzolinii* may be small in comparison with the other species in this group.

We deposited the eggs in the herpetological collection of Universidad Nacional de San Juan. We thank Rodrigo Acosta and Sol Acosta for capturing and care of the specimen.

Submitted by **JUAN CARLOS ACOSTA** (e-mail: jcacostasanjuan@gmail.com)**, ALEJANDRO LASPIUR,** and **GRACIELA BLANCO,** Departamento de Biología, Facultad de Ciencias Exactas, Físicas y Naturales, Universidad Nacional de San Juan. Avenida Ignacio de la Roza 590 (N), Caixa Postal 5400, San Juan, Argentina.

MASTIGODRYAS BIFOSSATUS (Swamp Racer). **PREDATION AND ECTOPARASITES**. *Mastigodryas bifossatus* is a large colubrid snake that occurs predominantly in open areas of South America. This species is active during the day and eats mainly frogs, small mammals and lizards (Leite et al. 2007. Rev. Bras. Zool. 24:729–734). On 15 September 2007 at 1643 h, we observed a snake being harassed by two Crab-eating Foxes (*Cerdocyon thous*) at the edge of a temporary pond in the Pantanal biome, Fazenda Nhumirim, municipality of Corumbá, State of Mato Grosso do Sul, Brazil (18.9927ºS, 56.6477ºW, datum WGS84). The foxes bit the snake one at a time, until one of them carried the snake to a forest near the pond. The other fox also ran toward the forest, but when approached, both foxes fled. Upon close examination, the snake was identified as *M. bifossatus* and was found to host 13 ticks, which we collected and preserved in 70% alcohol. The ticks were identified as *Amblyomma dissimile* (10 males and 3 females) and were deposited in the Laboratório de Parasitologia of the Instituto de Pesquisas Veterinárias Desidério Finamor, Rio Grande do Sul State, Brazil (NI 333). After collecting the ticks and photographing the snake we left the forest and the Crab-eating Foxes resumed feeding on the snake. Although Crab-eating Foxes are omnivorous, opportunistic hunters and commonly feed on small reptiles and other vertebrates (Gatti et al. 2006. J. Trop. Ecol. 22:227–230), this is the first record of them preying upon *Mastigodryas bifossatus*.

We thank CNPq/PELD (Process 520056/98-1) for financial support, Embrapa Pantanal for logistical support, Idea Wild for donation of a digital camera and laptop for the first author, Vanda Lúcia Ferreira for snake identification, and Valeria Castilho Onofrio and João Ricardo Martins for identification of ticks.

MICRURUS IBIBOBOCA (Caatinga Coral Snake). **PREDATION**. Spiders are potential predators of a number of small vertebrates, including amphibians (Del-Grande and Moura 1997. Herpetol. Rev. 28:147; Menin et al. 2005. Phyllomedusa 4:39–47) and birds (Peloso and Sousa 2007. Rev. Bras. Ornitol. 15:461–463; Teixeira et al. 1991. Ararajuba 2:69–74). However, predation events are rarely observed in the wild or published (Martins et al. 1993. Amphibia-Reptilia 4:273–296), and we are unaware of any report of predation on *Micrurus ibiboboca* by spiders. Here we report on the attempted predation of a juvenile *M. ibiboboca* by a spider, *Pachistopelma rufonigrum* (Araneae, Theraphosidae).

The event was observed on 27 March 2009, in an area of Atlantic Forest within the Serra de Itabaiana National Park (10.7489°S, 37.3419°W, datum SAD-69) in the Brazilian state of Sergipe. The spider immobilized the snake in leaf litter on the forest floor for four minutes. Subsequently, the snake writhed vigorously and was eventually able to escape. A video and four photographs documenting the event were deposited in the

NERODIA SIPEDON INSULARUM (Lake Erie Watersnake). **OFFSPRING RETENTION AND MORTALITY.** We observed several instances of mortality in gravid female *Nerodia sipedon insularum* following retention of fully formed embryos over the hibernation period. The first occurrence was on 5 June 2006, when we captured an adult female *N. s. insularum* (SVL = 990 mm; 564 g) on Green Island (Lake Erie, Ottawa Co., Ohio, USA) that was extremely lethargic and visibly emaciated except for a large swelling in the posterior third of her body. Upon further examination, we noted scrape wounds on both the dorsal and ventral sides surrounding this swelling. Palpation revealed the presence of distinct lumps within the swollen area similar in feel to developing embryos in gravid females. Because Lake Erie Watersnakes give birth between late August and early October (King 1986. Copeia 1986:757–772), any offspring she might have been carrying would have been retained from the previous year. The snake was held for observation for 17 days, during which time she refused food and remained lethargic. On 23 June 2006, we chose to euthanize the snake via injection of sodium pentobarbital, and performed a gross necroscopy. Fourteen fully developed deceased offspring were removed from both oviducts, confirming that this snake had retained offspring from the previous year.

On 31 May 2007, we encountered another female *N. s. insularum* (SVL = 737 mm; 198 g) from the South Bass Island State Park (Lake Erie, Ottawa Co., Ohio, USA) that appeared as though she had retained offspring. We noted this within our capture records, but chose to release her. We also noted possible retained offspring in three other females captured within this same week, but released them as well. We captured the State Park female again 9 June 2007 and on 20 June 2007, at which time we noted that she had visible trauma to the cloaca (heavy abrasion and oozing) and had lost almost 50 g (from 198 g to 153 g). After cleaning the abraded area we found a fully formed, partially decayed offspring protruding from the cloaca and blocking the passage of feces and urates. We successfully removed the offspring and held the female for observation but she died prior to receiving veterinary care. Post-mortem examination revealed four additional offspring (three of which were clumped together in an elongate mass) and one undeveloped yolk retained within her reproductive tract.

On 18 June 2009, we encountered yet another adult female *N. s. insularum* on the beach at the South Bass Island State Park (Lake Erie, Ottawa Co., Ohio, USA) that appeared to be near death (limp, lethargic, no righting response). This snake died during transport back to our laboratory. We palpated the lower third of the body and felt several large hard masses. Gross necroscopy revealed 12 full term offspring, one partially developed offspring with a small yolk attached, and one large unfertilized yolk retained within the reproductive tract.

The frequency of our observations (three different confirmed

FIG. 1. A dead *Nerodia sipedon insularum* from Pelee Island, Ontario, Canada, was found to contain 21 retained offspring from the previous year.

instances in the past four years and four other suspected, but unconfirmed cases), led us to search for other researchers who might also have unreported observations of this type of mortality. These queries resulted in an additional case of offspring retention in *N. s. insularum* noted in Lake Erie by one of us (DDJ). On 19 April 2004, an adult female *N. s. insularum* (SVL = 870 mm; 500 g) was captured on the northeast corner of Pelee Island (Lake Erie, Essex Co., Ontario, Canada). This snake appeared unusually heavy-bodied for so early in the season, and had a noticeable bulge on her right side, mid way down the thickened portion of her body, about 3 cm in size. Immediately anterior to this bulge was a small puncture wound, ca. 0.5 cm in diameter, that was dried around the edges (no blood or fluid present), presumably representing an old injury. The female was weighed, measured, PIT tagged, and released at the site of capture. On 5 May 2004 during a survey of the same location, the snake was found in the open and appeared to be basking, but was freshly deceased. Collection of this female was not possible, but a quick dissection was performed in the field. Twenty-one neonates were removed from this female, the most posterior of which was in a hardened egg-shaped mass (Fig. 1). The other neonates were in various states of decay, with the anterior young seeming more decomposed than the posterior. Many were noted as appearing to be shedding.

Other researchers have observed the retention of embryos by viviparous snakes but have not reported any adverse affects on the female. Shine (1977. Aust. J. Zool. 25:655–666) recorded the presence of ectopic embryos in several species of elapid snakes (*Notechis scutatus*, *Pseudechis porphyriacus*, and *Austrelaps superbus*) but noted that they were in the process of resorption. He further postulated the retention of these offspring may have been caused by an injury in the previous breeding season, as may have been the case in the *N. s. insularum* observed in 2004. Another instance of offspring retention in *Acrochordus javanicus* was noted in which a female was found to contain three full term embryos that had been encapsulated in a damaged oviduct and retained for at least six months (Shine et al. 1995. J. Herpetol. 29:352–360). Magnusson (1979. Copeia 1979:744–745) recorded an instance of a "mummified" embryo inside an *Acrochordus arafurae* that had been isolated for seven years. Shine et al. (*op. cit.*) hypothesized that female acrochordids may have the ability to maintain these dead encapsulated offspring for long periods of time.

The reasons why these particular female *N. s. insularum* retained offspring are unknown (e.g., previous injury, blockage by a hardened yolk mass, or lack of adequate gestation time), however, the consequences (lethargy, visible emaciation, external trauma, and subsequent death) suggest that this is a previously unrecognized source of mortality for female *N. s. insularum* and potentially other natricines. Notably, three of the four additional adult females suspected of having retained offspring were not seen again in subsequent surveys. This source of mortality could impose selection on reproductive timing in temperate snake species, and affect the relative benefits of viviparity vs. oviparity, especially at northern latitudes.

OXYBELIS AENEUS (Brown Vinesnake). **REPRODUCTION**. *Oxybelis aeneus* is an arboreal colubrid snake that occurs from Arizona, USA to southeastern Brazil. Clutch sizes from populations in the USA and Mexico range from 3–8 (Goldberg 1998. Texas J. Sci. 50:51–56) and in Costa Rica from 2–6 (Goldberg 2005. Herpetol. Rev. 36:70; Solórzano 2004. Snakes of Costa Rica. Distribution, Taxonomy and Natural History. Instituto Nacional de Biodiversidad, Santo Domingo de Heredia, Costa Rica. 791 pp.). Herein, we present information on clutch sizes of *O. aeneus* from the state of Ceará, Brazil. We examined three females that contained oviductal eggs from the herpetology collection of Universidade Federal do Ceará (CHUFC). One female (CHUFC 213), collected in June 1971 from Limoeiro do Norte Municipality (5.14598°S, 38.09835°W, datum WGS84), SVL = 955 mm, contained seven oviductal eggs (maximum length = 36 mm). The second female (UFC 3148), collected in January 2008 from São Gonçalo do Amarante Municipality (3.60764°S, 38.96868°W), SVL = 790 mm, contained three oviductal eggs (maximum length = 35 mm). The third female (UFC 3215), collected in January 2009 from Pentecoste Municipality (3.79320°S, 39.27063°W), SVL = 1030 mm, contained nine oviductal eggs (maximum length = 27 mm). The clutch of nine eggs represents a new maximum clutch size for *O. aeneus*.

We thank Stephen R. Goldberg for providing valuable suggestions on the manuscript.

OXYBELIS FULGIDUS (Green Vinesnake). **FORAGING BEHAVIOR**. Adopting efficient foraging behavior is important for snakes, given that the time spent pursuing, capturing, and handling prey all affect the profitability of a prey item (Cooper and Anderson 2006. Herpetologica 62:356–365). There is immense variation in the behaviors used by snakes to locate and capture prey (Shine et al. 2004. Funct. Ecol. 18:16–24). Their behavioral repertoire ranges from ambushing to active foraging, and from constriction to the use of mild or toxic venoms. *Oxybelis fulgidus* has a widespread distribution from Mexico to Argentina; however, it is considered uncommon in Costa Rica (Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. Chicago Press, Chicago, Illinois. 934 pp.). At the Organization for Tropical

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. *Oxybelis fulgidus* seizing an *Ameiva festiva* lizard from the fork of a small limb.

Studies' La Selva Biological Station, one of the most heavily studied sites in the Neotropics, *O. fulgidus* has been observed only a few times (Guyer and Donnelly 2005. Amphibians and Reptiles of La Selva, Costa Rica and the Caribbean Slope. Univ. California Press, Berkeley. 299 pp.). Its semiarboreal habits, high speed, and extremely cryptic coloration make observing *O. fulgidus* in its natural habitat difficult.

At 1115 h on 3 August 2008, in Tirimbina Rainforest Center, Heredia Province, Costa Rica (10.4167ºN, 84.1167ºW, datum WGS84; elev. 180 m), two *O. fulgidus* were observed foraging in a light-gap of a late successional secondary forest near a swamp with abundant palms and a few small trees. The first individual (SVL ca. 125 cm) was lying horizontally with the posterior two-thirds of its body in two small bushes but with its head and the anterior one-third of its body held vertically from the fork of a small limb (Fig. 1). In that position, the snake had seized a very large (SVL ca. 13 cm) *Ameiva festiva* (Central America Whiptail Lizard) laterally by the head and was lifting it 0.5 m off the ground. Although the lizard kicked with its hind feet and moved its body frantically during the next 15 minutes, the snake showed no movement whatsoever. I observed blood on the snake's head and jaws, likely resulting from envenomenation of the lizard. Once the prey was dead, the snake, still in a vertical position, briefly released it. Then, using alternate movements of the lower and upper jaws, the snake started to swallow the prey headfirst. Once the snake reached the hind limbs of the lizard, it retracted its head to the limb fork, and holding its head in a horizontal position, swallowed the rest of the lizard in about 10 min. While the first individual was swallowing its prey, another *O. fulgidus* (SVL ca. 100 cm) was observed about 3 m away. This snake subsequently captured a small (SVL ca. 6 cm) *A. festiva* from the ground with a lateral bite on the neck, and then climbed up a 2-m tall tree. The snake then repositioned the lizard, and swallowed it in approximately five minutes.

From these observations, some comments are of note. First, both *O. fulgidus* were using the same microhabitat at the same time, probably because the high abundance of prey available at the site at that particular time made it especially suitable for foraging. Second, the larger *O. fulgidus* used the limb fork to facilitate ingestion of the prey (as in Norris and Burtt 1998. Herpetol. Rev. 29:243) and to help seize and lift the large prey item that might be have been risky to handle on the ground. Although this observation adds to our knowledge of the foraging behavior of *O. fulgidus*, microhabitat selection and feeding behavior of this species warrant further study.

I acknowledge Tirimbina Rainforest Center staff for support and permissions, and M. Barquero, M. Sasa, R. LaVal, and B. Flaherty for suggestions on the manuscript.

OXYRHOPUS PETOLA DIGITALIS (NCN). **PREDATION.** The dipsadids *Oxyrhopus petola* and *Philodryas patagoniensis* are widely distributed in South America, with *O. petola* ranging from southern South America to Mexico, and *P. patagoniensis* ranging from Brazil to Bolivia, Paraguay, Argentina, and Uruguay (Peters and Orejas-Miranda 1970. Bull. U.S. Natl. Mus. 297:1–347). *Oxyrhopus* are nocturnal and terrestrial, feeding primarily on lizards and rodents (França et al. 2008. Copeia 2008:23–38; Strussmann and Sazima 1993. Stud. Neotrop. Fauna Environ. 28:157–168). *Philodryas patagoniensis* is a diurnal and predominantly terrestrial species that feeds on a wide variety of small vertebrates, particularly amphibians, lizards, mammals, birds, and occasionally snakes (Hartmann and Marques 2005. Amphibia-Reptilia 26:25–31; Rocha and Vrcibradic 1998. Ciência e Cultura 50:364–368). Here we report an adult female *O. petola* suffering a predation attempt by *P. patagoniensis* in a patch of restinga (coastal sand dune shrubland habitat) in the municipality of Iguaba Grande (22.8547°S, 42.1955°W, datum WGS 84), state of Rio de Janeiro, southeastern Brazil.

At 1630 h on 2 November 2008 one of us (MBV) and L. Freire found an adult *P. patagoniensis* (total length ca. 140 cm) with the anterior portion of its body (ca. 30 cm) inserted in a cavity on a 40 cm high bank of sand bordering a narrow dirt road. When the snake was spotted, we suspected that it might be preying on something inside the cavity. However, as soon as the snake noticed us, it fled rapidly to the nearest bush. We then checked the cavity and found the tip of a snake tail exposed. After digging a bit, we removed a live *O. petola* (SVL = 71 cm; total length = 91 cm) from the hole. There were several bite marks on the posterior

part of its body, and it is probable that the *P. patagoniensis* had already started to swallow it tail-first when we arrived. We kept the wounded snake under veterinary care, but it died two days later and was deposited at the reptile collection of the Museu Nacional, Rio de Janeiro (MNRJ 17927).

In southern Brazil (state of Rio Grande do Sul), Hartmann and Marques (*op. cit.*) reported the colubrids *Liophis poecilogyrus* and *Pseudablabes agassizi*, as well as a conspecific, as prey of *P. patagoniensis*. Two other cannibalistic events were reported by Pontes et al. (2003. Herpetol. Rev. 34:154) in the same state. In northeastern Argentina, Lopez and Giraudo (2008. J. Herpetol. 42:474–480) recorded a relatively high frequency of snakes in the diet of *P. patagoniensis* (13 of a total of 92 food items were snakes); nevertheless, only two snake species could be identified: *L. jaegeri* and *L. dilepis*. Thus, although some cases of ophiophagy have previously been reported for *P. patagoniensis*, our record from Iguaba Grande is the first one involving a species of the genus *Oxyrhopus*.

We are grateful to Luiz Freire for assistance in field, to A. L. Silveira for confirming the identification of the *O. petola*, and to D. Vrcibradic for contributions to the manuscript and for reviewing the English. M. B. Vecchi received a postdoctoral fellowship from FAPERJ (E-26/100.162/2008).

PANTHEROPHIS ALLEGHANIENSIS (Eastern Ratsnake). **DIET.** At 0830 h on 12 May 2009, a *P. alleghaniensis* was observed in the act of constricting a live bat (Fig. 1). The bat was almost certainly a Northern Yellow Bat (*Lasiurus intermedius*) but could potentially be an Eastern Red Bat (*L. borealis*). The bat was struggling and emitting a high-pitched cry as the snake constricted its torso. The snake was ca. 60 cm in total length and the bat was an adult male with a forearm length near the species average of 48 mm (Webster et al. 1980. Mammal. Species 132:1–3). The two were on the edge of a sidewalk along Museum Road on the campus of the University of Florida, in Gainesville, Florida USA. The sidewalk was adjacent to a Sabal Palm (*Sabal palmetto*) and also near several holly bushes (*Ilex* sp.).

The most likely scenario that led to this observation is that the snake captured the bat in the palm tree (ca. 5 m tall) and the two subsequently fell together to the sidewalk, where their struggle continued. When the two were revisited at 0850 h, the bat was dead and the snake was attempting to consume it. The snake appeared small relative to the bat and consumption of the large bat did not appear possible unless the snake managed to fold the wings significantly. At 0856 h both snake and deceased bat were moved out of harm's way from the sidewalk to the holly bushes.

Prior records of ratsnakes feeding on bats were limited to *Eptesicus*, *Myotis*, *Pipistreullus*, and *Tadarida* (Ernst and Ernst 2003. Snakes of the U.S. and Canada. Smithsonian Inst. Press, Washington, DC. 668 pp.). A Mexican Freetail Bat, *Tadarida brasiliensis*, was found in the gut of a *P. obsoletus* (Ridlehuber and Silvy 1981. Southwest. Nat. 26:70–71). In addition, *P. alleghaniensis* has been recorded feeding upon Big Brown Bats, *Eptesicus fuscus fuscus* (Boyles and Storm 2007. Behaviour 144:1019–1032; Silver 1928. J. Mammal 9:149) as well as bats of the genus *Myotis* (e.g., Indiana Bat, *M. sodalis*: Barr and Norton 1965. J. Mammal. 46:672; Cary et al. 1981. Trans. Kansas Acad. Sci. 84:223–224). Predation of the Georgian Bat, *Pipistrellus subflavus*, by a captive ratsnake has also been noted (Fowler 1947. Copeia 1947:210). This is the first published evidence of a wild *Pantherophis* preying upon a bat of the genus *Lasiurus*.

PANTHEROPHIS OBSOLETUS (Texas Ratsnake). **DIET AND FORAGING BEHAVIOR**. The contents of bird nests are important prey for *Pantherophis obsoletus* (Fitch 1963. Copeia 1963:649–658), a major nest predator in some areas (Stake et al. 2005. J. Herpetol. 39:215–222). *Pantherophis* are known to be intraspecifically social during certain activities such as male-male combat (Stickel et al. 1980. Am. Midl. Nat. 103:1–14), but we are not aware of any recorded instances of group nest depredation in this species.

On 15 July 2007, we filmed two *P. obsoletus* simultaneously engaged in the depredation of an Indigo Bunting (*Passerina cyanea)* nest (http://www.biosci.missouri.edu/avianecology/cox/video.htm). We recorded the event using an infrared camera system that continuously monitored the nest on the Baskett Research and Education Area in Boone Co., Missouri, USA. The nest was located 0.45 m above the ground in a small shrub near a forest edge. A single *P. obsoletus* began depredation of the nest at 2048 h. A second *P. obsoletus* arrived at the nest at 2053 h. The video sequence demonstrated that both individuals engaged in foraging behavior (i.e., consumption of nestlings or a search of the nest interior). The depredation event ended at 2057 h after

both the nestlings were consumed.

The field of view of the camera was insufficient to determine if the snakes hunted cooperatively, though the 5 min lag between the onset of the event and the arrival of the second individual suggests that this is unlikely. *Pantherophis* are attracted to edge habitats (Blouin-Demers and Weatherhead 2001. Ecology 82:2882–2896) such as the site of this observation, so it is possible that the activities of the first *P. obsoletus* attracted a nearby individual. To our knowledge, this is the first documented occurrence of a songbird nest being depredated by multiple individuals of *P. obsoletus.*

PHILODRYAS MATTOGROSSENSIS (Two-colored Racer). **DIET.** *Philodryas mattogrossensis* is a medium-sized, terrestrial colubrid found in Argentina, Bolivia, Brazil, and Paraguay (Thomas 1976. Unpubl. PhD. thesis. Texas A&M University). Life history data on this species are lacking. Here I report a new anuran diet item for *P. mattogrossensis*.

At 1300 h on 29 April 2009, a *P. mattogrossensis* (SVL = 1014 mm; tail length = 440 mm; 270 g post prey removal) was captured in a pile of adobe bricks in the Isoceño community of Yapiroa, Provincia Cordilleria, Departmento Santa Cruz, Bolivia (19.6000°S, 62.5667°W, datum WGS84). When the snake's stomach was checked for food by forced regurgitation, it regurgitated an adult *Leptodactylus bufonius* (Shovel-nosed Chamber Frog; SVL = 60 mm). *Philodryas mattogrossensis* has been described as an opportunistic feeder (Amaral 1933. Bol. Bio. 1:2–4), but this is the first record of *L. bufonius*, an anuran commonly found in the Gran Chaco (Cei 1980. Monitore Zool. Ital. Monogr. 2:1–609; pers. obs.), in the diet of *P. mattogrossensis*.

Funding for this research was provided by the Applied Biodiversity Science National Science Foundation Integrated Graduate Education and Research Traineeship doctoral program (NSF-IGERT Award #0654377) at Texas A&M University.

PSEUDOERYX PLICATILIS (South American Pond Snake). **DIET**. The aquatic colubrid snake *Pseudoeryx plicatilis* is distributed in Amazon lowland rainforests and also in the Chaco of northern Argentina and Paraguay (Peters and Orejas-Miranda 1970. Catalogue of the Neotropical Squamata. Part I. Snakes. Bull. U.S. Nat. Mus. 297, Washington D.C. 347 pp.). Despite its wide distribution, *P. plicatilis* is seemingly rare and little is known about its natural history (Schargel et al. 2007. Herpetologica 63:236–244). Fishes and frogs are reported to compose the diet of *P. plicatilis* (Amaral 1978. Serpentes do Brasil: Iconografia Colorida. Editora da Universidade de São Paulo, Melhoramentos, São Paulo. 248 pp.; Starace 1998. Guide des Serpents et Amphisbènes de Guyane. Ibis Rouge Editions, Guadeloupe. 452 pp.), but there are few specific reports of this species' diet in the literature. Here we report an observation of a freshwater eel, *Synbranchus* sp. (Teleostei: Synbranchidae), as prey of *P. plicatilis*.

On 8 May 2009, at 1400 h, an adult male *P. plicatilis* (SVL = 714 mm; tail length = 162 mm) was seen in the water ingesting a freshwater eel headfirst. The snake was collected near the Unini River's southern margin (01.7658°S, 62.2247°W, datum WGS 84), Barcelos, Amazonas, Brazil, and was maintained in a snake bag for ca. 10 min. During that time, the snake regurgitated a *Synbranchus* sp. (total length = 349 mm). Both specimens were deposited at their respective collections at the Instituto Nacional de Pesquisas da Amazônia (*P. plicatilis* = INPA-H 25370; *Synbranchus* sp. = INPA 32629).

We thank Albertina P. Lima and Niro Higuchi for providing us with field opportunities at Rio Unini, and Jansen S. Zuanon for the fish identification.

Submitted by **IGOR LUIS KAEFER** (e-mail: igorkaefer@hotmail.com), and **ANELISE MONTANARIN** (e-mail: aneta_bio@yahoo.com.br), Coordenação de Pesquisas em Ecologia, Instituto Nacional de Pesquisas da Amazônia, CP 478, 69011-970, Manaus, Amazonas, Brazil.

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Gartersnake). **HIBERNACULA.** On 14 April 2008 at 1400 h we counted 25 *Thamnophis s. sirtalis* crawling out of a hole under an oak leaf located at the Bartlett Arboretum in Stamford, Fairfield Co., Connecticut, USA (41.1338°N, 73.7955°W, datum NAD 83). The day was partially sunny and the temperature was 11°C. We removed the leaf when snakes stopped emerging and observed that the hole was smaller than the diameter of a US quarter (23.5 mm). At first this opening seemed too small to permit the passage of these adult snakes. However, measurements of a random sample of 18 Fairfield Co. adult *T. sirtalis* from the Yale Peabody Museum of Natural History yielded an average head width of 11.90 mm at widest point and an average of 8.57 mm in head height (measured from the posterior-most end of the chin shields to the parietal). Thus, this inconspicuous hole would easily provide these snakes with access to the surface from their hibernaculum.

The hole was embedded in loamy soil surrounded by a labyrinth of decomposing root channels in a northeastern deciduous forest comprised primarily of beech, birch, and oak trees. This hole was located 26.5 m NW of a southerly flowing brook, ca. 1.5 m above the water level. Excavation of a test hole and probing with flexible fiberglass sticks revealed a vertical depth of 55.9 cm. Lateral side tunnels 19.1 cm long were observed at a vertical depth of 15.2 cm. Two additional surface holes were found in close proximity of our test hole, 86.4 cm and 71.1 cm away. These had vertical depths of 21.6 cm and 22.9 cm, respectively. Such a mesophytic habitat can provide a moist and humid environment that is covered in the fall by a leaf mat that traps moist warm air. This may help to insulate the holes and underground labyrinth, preventing desiccation or freezing in the winter. In the past, ant mounds with numerous small (6–25 mm diameter) entrances

have been reported to provide access to tunnels for yearling and adult *T. sirtalis* in Michigan (Carpenter 1953. Ecology 34:74–80), and Carpenter's account is consistent with the size of the hole we report here. Hibernation is a critical but poorly-understood aspect of the natural history of many snake species and knowledge of situations that provide suitable hibernacula improves our ability to conserve important habitats for these species.

We thank the students of the Western Connecticut State University Herpetology Class for their observations, and Greg Watkins-Colwell, Yale Peabody Museum of Natural History, for reviewing the manuscript and help in accessing specimens.

WAGLEROPHIS MERREMII (Wagler's Snake). **FEEDING BEHAVIOR.** Snakes of the monotypic genus *Waglerophis* occur in South America and feed mainly on bufonid anurans (Jordão 1996. Estudo Comparativo da Alimentação e da Reprodução de *Waglerophis merremii* e *Xenodon newiedii* (Serpentes: Colubridae). USP-SP. 93 pp.). In the Brazilian Caatinga biome, *W. merremii* preys primarily on *Rhinella jimi* (Lima-Verde 1991. Estado Atual do Conhecimento da Fauna Reptiliana do Ceará. Universidade Federal do Ceará, Fortaleza. 209 pp.). On 2 June 2008 we observed a *W. merremii* (CHUFC 3040) in coastal vegetation ("mata de tabuleiro") of São Gonçalo do Amarante Municipality, Ceará, Brazil (03.304856ºS, 38.552752ºW, datum WGS84), preying on an adult *Rhinella jimi*. We captured the snake for studies at the Núcleo Regional de Ofiologia da Universidade do Ceará (NUROF-UFC), Brazil. When we examined the snake's cage the following day, we found a pile of viscous material (Fig. 1A) containing parts of coleopterans (Family Scarabeidae; Fig. 1B), typical prey of *Rhinella jimi* (Cei 1972. *In* Blair [ed.] Evolution of the Genus *Bufo*, pp. 82–92. Univ. Texas Press, Austin). We offered additional *R. jimi* to the same snake on 2 July 2008 and to another *W. merremii* (CHUFC3041) from the "mata de tabuleiro" of Caucaia, Ceará (03.282088ºS, 38.552752ºW) on 18 August 2008. The toads also were originally from the same coastal vegetation of Caucaia Municipality. In both cases, the snakes began ingestion at the prey's head, as expected, but around eight minutes after deglutition, regurgitated material similar to that noted in the first observation. We observed that during the ingestion phase, the snakes regurgitated only the toad's stomach contents and never any part of the anuran.

We believe that the likely mechanism for this behavior is that the toad regurgitates within the snake's stomach. The snake subsequently regurgitates the coleopterans, which are probably toxic. Many instances of snakes regurgitating whole prey have been reported in the literature; but, to our knowledge, none report regurgitation of only the prey's stomach contents. Although the behavior has been observed on three occasions in two individual *W. merremii*, it is not always exhibited when a *Waglerophis* consumes a toad.

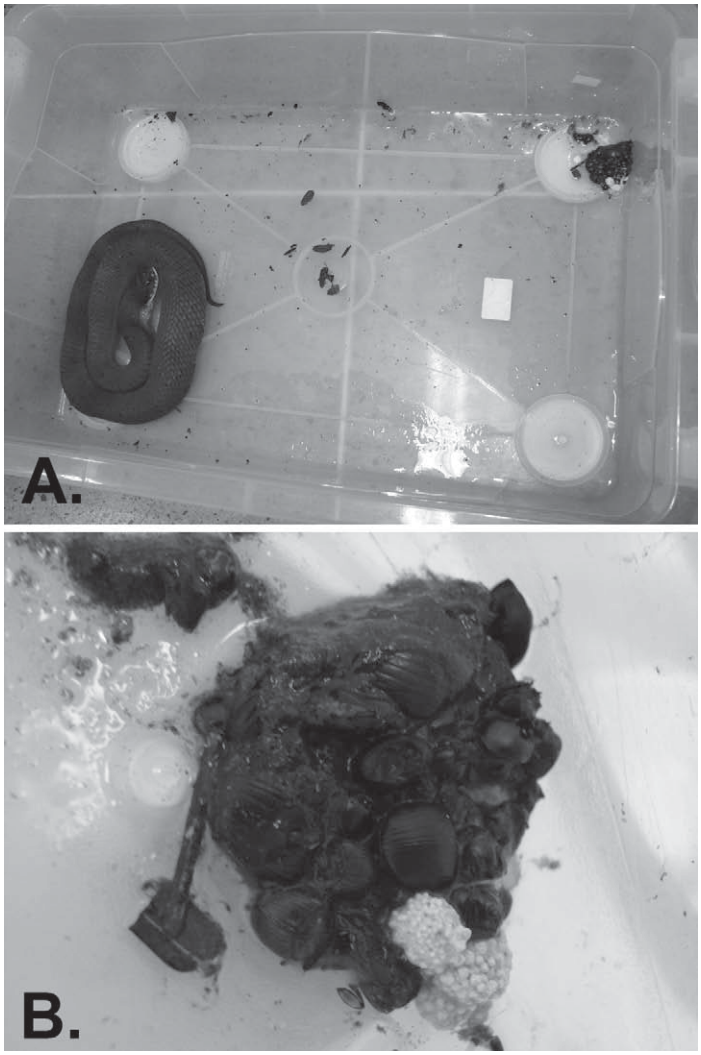

FIG. 1. *Waglerophis merremii* with material regurgitated soon after ingesting a *Rhinella jimi* (A). Close examination of the material reveals parts of coleopterans (Scarabeidae) but no anuran material (B), suggesting that the material represents the toad's stomach contents.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 41, Number 1 (March 2010, p. 102). Please note that the responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extension reports unless a thorough literature review has been completed.

CAUDATA — SALAMANDERS

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: ARKANSAS: Craighead Co.: Lake City Township: 0.01 km N of St. Hwy 18 (35.82098ºN, 90.43948ºW; NAD 83). 14 March 2008. Phillip Jordan. Verified by Stan Trauth. Arkansas State University Museum of Zoology (ASUMZ 30959). New county record (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.); known previously from adjacent Greene County and seven other eastern Arkansas counties and from eight southern Arkansas counties.

Submitted by **PHILLIP N. JORDAN**, 91 Skylark Lane, Lake City, Arkansas 72437, USA; e-mail: phillipnjordan03@hotmail.com.

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). USA: ARKANSAS: Howard Co.: Mine Creek, 2.4 km SE Nashville (more detailed specifics not available). 23 July 1953. H. S. Sublette. Henderson State University (HSU 521). Clark Co.: SE of Arkadelphia, Deceipher Creek near jct. with Ouachita River. August 1998. Collector name not recorded. HSU 833. Both specimens verified by Stan Trauth. Specimens each represent first county records. Clark Co. record extends range ca. 65 km NNW nearest record in Union Co., and Howard Co. record extends range ca. 65 km N of the nearest record in Lafayette Co. (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press. Fayetteville. 421 pp.)

Submitted by **RENN TUMLISON**, Department of Biology, Henderson State University, Arkadelphia, Arkansas 71999, USA.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: ARKANSAS: Woodruff Co.: Specimens were found near Brushy Lake Road on the Cache River National Wildlife Refuge 0.2 miles S of AR 260 W (35.21080ºN, 91.26437ºW; WGS84; elev. 53 m). 21 May 2010. Thomas J. Belford. University of Kansas Natural History Museum (KUDA 012136). Verified by William E. Duellman. First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas, Univ. Of Arkansas Press, Fayetteville. 421 pp.). Extends range ca. 22 km from nearest known record from White Co., Arkansas. Two specimens were found beneath a decaying log on the forest floor.

Submitted by **THOMAS J. BELFORD**, 701 W Academy Avenue, Searcy, Arkansas 72143, USA; e-mail: thomasbelfordiniraq@yahoo.com.

PLETHODON ALBAGULA (Western Slimy Salamander). USA: ARKANSAS: Prairie Co.: Near Holloway Memorial Natural Area, 0.54 miles N of State Highway 11 on Allred Drive (35.06930ºN, 91.54400ºW; WGS84; elev. 64 m). 07 May 2010. Thomas J. Belford. University of Kansas Natural History Museum (KUDA 011949). Verified by William E. Duellman. First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Of Arkansas Press, Fayetteville. 421 pp.). Extends range 20.5 km from nearest known record inWhite Co., Arkansas. Single specimen was found beneath a rotting log on a flatwoods forest floor.

Submitted by **THOMAS J. BELFORD**, 701 W Academy Avenue, Searcy, Arkansas 72143, USA; e-mail: thomasbelfordiniraq@yahoo.com.

ANURA — FROGS

ANAXYRUS AMERICANUS (American Toad). USA: INDIANA: Clay Co.: northeast of Clay City (39.30762ºN, 87.06380ºW; NAD 83). 15 April 2010. Sarabeth Klueh and Jason Mirtl. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2010f). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii–404 pp.) Individuals were calling from farm pond along with *Anaxyrus fowleri*. This species occurs commonly throughout most of Indiana but appears to be largely absent from a pocket of counties in the southwest part of the state (Minton, *op. cit*.). This record partially fills a gap in the range of this species in southwest Indiana.

Submitted by **SARABETH KLUEH** (e-mail: sklueh@dnr.in.gov) and **JASON MIRTL**, Wildlife Diversity Section, Indiana Department of Natural Resources Division of Fish and Wildlife, 553 E. Miller Drive, Bloomington, Indiana 47401, USA.

ANAXYRUS AMERICANUS (American Toad). USA: INDIANA: Vermillion Co.: Clinton Township (39.62180°N, 87.51672°W; NAD 83). 30 March 2010. Sarabeth Klueh and Jason Mirtl. Illinois Natural History Survey (INHS 2010b). Vouchers for a second Vermillion Co. location were also obtained (INHS 2010c). Both specimens verified by Chris Phillips. New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii–404 pp.). Adults in Clinton Twp. were calling from a vernal pool in a farm field. Adults in Highland Twp. were calling from a small pond in the front yard of a farmhouse. These records partially fill a gap in the range of this species in western Indiana.

Submitted by **SARABETH KLUEH** (e-mail: sklueh@dnr.in.gov) and **JASON MIRTL**, Wildlife Diversity Section, Indiana Department of Natural Resources Division of Fish and Wildlife, 553 E. Miller Drive, Bloomington, Indiana 47401, USA; and **NATHAN ENGBRECHT**, 135 Holmstedt Hall, Indiana University School of Medicine-Terre Haute, Indiana State University, Terre Haute, Indiana 47809, USA (e-mail: nengbrecht@indstate.edu).

ANAXYRUS FOWLERI (Fowler's Toad). USA: INDIANA: Clay Co.: northeast of Clay City (39.30762°N, 87.06380°W; NAD 83). 15 April 2010. Sarabeth Klueh and Jason Mirtl. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2010g). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii–404 pp.). Individuals were calling from farm pond along with

Anaxyrus americanus.

Submitted by **SARABETH KLUEH** (e-mail: sklueh@dnr.in.gov) and **JASON MIRTL**, Wildlife Diversity Section, Indiana Department of Natural Resources Division of Fish and Wildlife, 553 E. Miller Drive, Bloomington, Indiana 47401, USA.

ELEUTHERODACTYLUS COQUI (Puerto Rican Coquí). COSTA RICA: CARTAGO: Distrito Turrialba, Barrio Jorge Debravo (09.900001°N, 83.666768°W; datum not available; 622 m elev.). 01 July 2009. A. García-Rodríguez, C. Chaves, M. Wainwright, and A. Villegas. Verified by Rafael L. Joglar. UCR 20746–47. First records of *E. coqui* in Costa Rica (Frost 2009. Amphibian Species of the World: an Online Reference. Version 5.3 [12 February 2009]) and both were part of a chorus of over 100 males in an area of about 100 x 400 m in size within a residential neighborhood. Originally a Puerto Rican endemic, *E. coqui* has invaded the Bahamas, the Dominican Republic, Ecuador, Guam, New Zealand, and parts of the United States (Global Invasive Species Database [http://www.issg.org/database], downloaded 13 July 2009). We know of no other population in Costa Rica, but the dispersal of this exotic species or its introduction to other areas of the country are of concern to wildlife biologists alarmed with the effects of invasive species on local ecosystems.

Submitted by **ADRIÁN GARCÍA-RODRÍGUEZ** (e-mail: garciar.adrian@gmail.com), **GERARDO CHAVES** (e-mail: cachi13@gmail.com), **MARK WAINWRIGHT** (e-mail: markwainwright@racsa.co.cr), and **ALEXANDER VILLEGAS** (e-mail: alexmont@costarricense.cr), Museo de Zoología, Departamento de Biología, Universidad de Costa Rica, San José, Costa Rica.

HYLA WRIGHTORUM (Arizona Treefrog). USA: NEW MEXICO: McKinley Co.: Marquez Wildlife Area. 250 m E of Ojo de Marquez, Cañon de Marquez and 3.2 km WNW of Marquez, Sandoval Co.. (35.3246°N, 107.3353°W; WGS84; elev. 2224 m). 30 July 2009. J Tomasz Giermakowski, Cassandra M Wilson, and Howard L Snell. Verified by Michael J. Sredl. University of New Mexico Museum of Southwestern Biology (MSB 76435 [lot of two tadpoles]). New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque, xix + 431 pp.). First record in the Chivato Mesa/Mount Taylor region of Cibola, McKinley, and Sandoval counties of New Mexico. Extends the known range by ca. 80 km ENE of the nearest verified locality at El Malpaís National Monument, Cibola Co., New Mexico (Monatesti et al. 2005. Herpetol. Rev. 36:74–75; USGS Biological Surveys Collection BS/FC 7837–39, now MSB 87837–39, listed in *op. cit*. as BS/FC 7818–20). These records, as well as an unidentifiable 19th century specimen from Nutria, McKinley Co. (Gehlbach 1965. Proc. U.S. Nat. Mus. 116[3505]:243–332), indicate that the species may be present throughout other relatively isolated mountains in the region.

Collection was made under New Mexico Department of Game and Fish authorization #3329.

Submitted by **J. TOMASZ GIERMAKOWSKI (**e-mail: tomas@unm.edu), **CASSANDRA M. WILSON**, and **HOWARD L. SNELL**, Museum of Southwestern Biology, MSC03 2020, University of New Mexico, Albuquerque, New Mexico 87131-0001, USA.

HYPSIBOAS EXASTIS. BRAZIL: PERNAMBUCO: Municipality of Jaqueira: Reserve Private Frei Caneca (08.73061°S, 35.84606°W; WGS 84; elev. 600 m). 10 November 2007. S. P. Lima dos Santos and E. Maranhão dos Santos. Coleção Herpetologica da Universidade Federal Rural de Pernambuco, Unidade Acadêmica de Serra Talhada, Serra Talhada, Pernambuco, Brazil (CHUFRPE 904, adult specimen SVL 70.2 mm). Verified by M. Trefault Rodrigues. Previously known only from the type locality: Fazenda Unacau, Municipality of São José da Vitoria, State of Bahia (Caramaschi and Rodrigues 2003. Arq. Mus. Nac., Rio de Janeiro 61[4]:255–260). First state record, extends the known distribution 800 km northeast from type locality.

Submitted by **SUENY PALOMA LIMA DOS SANTOS,** Universidade Federal de Pernambuco, Centro de Ciências Biológicas Av. Prof. Moraes Rego, 1235 - Cidade Universitária, 50670-901, Recife, PE, Brazil; and **EDNILZA MARANHÃO DOS SANTOS**, Unidade Acadêmica de Serra Talhada, Universidade Federal Rural de Pernambuco, 56900-000, Serra Talhada, PE, Brazil.

HYPSIBOAS ROSENBERGI (Medium Gladiator Frog). PANAMÁ: COLON: Barro Colorado Island: Barro Colorado Nature Monument, upper lab clearing (9.16298ºN, 79.83795ºW; NAD83). 06 July 2009. Robert V. Horan III and Edward Hurme. Verified by Roberto Ibáñez. Smithsonian Tropical Research Institute Digital File Manager, reference numbers 30522–30525. First records (two males and a female) from Barro Colorado Island (Rand and Myers 1990. *In* Gentry [ed.], Four Neotropical Forests, pp. 386–409. Yale Univ. Press, New Haven, Connecticut). Because the herpetofauna of Barro Colorado Island has been surveyed extensively over the last 80 years (Rand and Myers 1990, *op. cit.*) and because the mating call of this species is loud and conspicuous (the two males were vocalizing), we view the species as being a recent colonist to the island. The addition of *H. rosenbergi* to Barro Colorado Island raises the number of amphibian species occurring there to 35 (Ibáñez et al., 1999. The Amphibians of Barro Colorado Nature Monument, Soberania National Park and Adjacent Areas. Mizrachi and Pujol Editorial, Panama). The vegetation community at the site is tropical moist forest.

Submitted by **ROBERT VINCENT HORAN III,** D. B. Warnell School of Forestry and Natural Resources, University of Georgia, Athens, Georgia 30602, USA (e-mail: rvhoran@uga.edu); and **EDWARD R. HURME**, Department of Ecology and Evolutionary Biology, Princeton University, Princeton, New Jersey 08544, USA (e-mail: ehurme@princeton.edu).

LITHOBATES SEPTENTRIONALIS (Mink Frog). CANADA: ONTARIO: Michipicoten Island Provincial Park: Forested beaver dam complex (47.72777°N, 85.82694°W, NAD 83). 09 May 2010. Benjamin Kuchta. Verified by Stephen Hecnar and Amy Lathrop. Royal Ontario Museum (ROMdm 00268, digital photograph). First island record (Oldham and Weller 2000. Ontario Herpetofaunal Atlas. National Heritage Information Centre, Ontario Ministry of Natural Resources. http://nhic.mnr.gov.on.ca/MNR/nhic/herps/ohs.html [updated 10-01-2010]).

Several individuals were observed in a large, lowland beaver dam complex. Mink Frogs were not previously known to inhabit Michipicoten Island, the third largest island in Lake Superior. The island is 16 km from shore at its nearest point and the record is 40 km SW of the nearest confirmed Mink Frog location. These populations are likely genetically isolated and may represent novel opportunities for study.

Submitted by **BENJAMIN KUCHTA**, Department of Natural Resources Management, Lakehead University, 955 Oliver Road, Thunder Bay, Ontario, Canada, P7B 5E1; e -mail: bkuchta@lakeheadu.ca.

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). USA: FLORIDA: Nassau Co.: Fort Clinch State Park, Fernandina Beach, 0.2 km E of Willow Pond (30.69816°N, 81.445638°W; WGS 84; elev. 1 m). 04 August 2009 and 21 October 2009. Lisa M. Wilson. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 157779–84). New county record. Extends the range ca. 45 km north of the closest known verified locality in Duval Co. (UF 140832; also see Krysko et al. 2005. Herpetol. Rev. 36:85–87). Six gravid females collected from PVC refugia.

Submitted by **LISA M. WILSON** and **DAVID L. BECHLER**, Department of Biology, College of Arts and Sciences, Valdosta State University, Valdosta, Georgia 31698, USA (e-mail: dbechler@valdosta.edu).

PHYSALAEMUS AGUIRREI (Linhares Dwarf Frog). BRAZIL: MINAS GERAIS: Municipality of Periquito, Fazenda Coqueria (19.1°S, 42.183°W; SAD 69; elev. 174 m). 16–19 September 2008. M. A. S. Canelas and R. Filogonio. Verified by L. B. Nascimento. Museu de Ciências Naturais, Pontifícia Universidade Católica de Minas Gerais, Belo Horizonte, Minas Gerais (MCNAM 11207–11031, 11036, and 11043). This represents the most inland record for the species and extends known distribution ca. 220 km airline W from Linhares and 240 km SW from Nanuque. *P. aguirrei* was only known from the type locality at Refúgio Sooretama, Linhares, Espírito Santo, Brazil (Frost 2009. Amphibian Species of the World: an Online Reference. Version 5.3, 12 February 2009. Electronic database accessible at http://research.amnh.org/herpetology/amphibia/); Caravelas, Bahia, Brazil (Van Sluys 1998. Herpetol. Rev. 29:49); and Nanuque, Minas Gerais, Brazil (Carvalho-Jr and Nascimento 2005. Herpetol. Rev. 36:200).

Submitted by **MARCO ANTÔNIO SCHETTINO CANELAS**, Herpeto Consultoria Ambiental LTDA, Rua Caraça 539, Serra, 30220-260, Belo Horizonte, MG, Brazil (e-mail: marcocanellas@hotmail.com); and **RENATO FILOGONIO**, Programa de Pós-Graduação em Zoologia, Universidade Estadual Paulista "Júlio de Mesquita Filho," Instituto de Biociências, Departamento de Zoologia, Avenida 24A, n.1515, Bela Vista, 13506-900, Rio Claro, SP, Brazil (e-mail: renatofilogonio@gmail.com).

PSEUDACRIS CLARKII (Spotted Chorus Frog). USA: TEXAS: DeWitt Co.: near Gonzales Co. Road 296 ca. 3.5 km NE of Cheapside, Texas (29.29131°N, 97.36864°W; WGS84). 12 April 2010. Romey Swanson and Christian Swanson. Verified by Travis LaDuc, Texas Natural History Collection (TNHC 82801). First county record (Dixon 2000. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station Texas. 421 pp.). On a night after heavy rains several choruses of *P. clarkii* were heard while we were working on the Carr Ranch located on the Gonzales/DeWitt county line. A single adult male was captured by hand in flooded hay field heavily encroached by mesquite (*Prosopis glandulosa*) and huisache (*Acacia farnesiana*). Specimen measured 2.8 cm SVL.

Submited by **ROMEY L. SWANSON** (e-mail: romeyswanson@gmail.com), **CHRISTIAN SWANSON,** and **THOMAS R. SIMPSON** (e-mail: r_simpson@txstate.edu), Department of Biology, Texas State University, San Marcos Texas 78666, USA.

SCINAX AROMOTHYELLA. BRAZIL: RIO GRANDE DO SUL: Munipalitity of Sertão: Parque Natural Municipal de Sertão (28.045665°S, 52.214153°W; WGS84; 650 m elev.). 30 May 2008. N. Zanella. Universidade de Passo Fundo, Passo Fundo, Rio Grande do Sul (CAUPF 2147). Verified by C. Haddad and J. Faivovich. Previously known from Chapecó, Santa Catarina (Lucas and Fortes 2008. Biota Neotrop. 8[3]:51–59), São Domingos and Ipuaçu, Santa Catarina, Brazil (Hartmann et al. 2008. *In* J. J. Cherem and M. Kammers [eds.], A Fauna das Áreas de Influência da Usina Hidrelétrica Quebra Queixo, pp. 89–110. Habilis Editora, Erechim), and Misiones Province, Argentina (Faivovich 2005. Herpetologica 61[1]:69–77). First state record, extends range ca. 250 km E from Misiones Province, Argentina and ca. 111 km S from Floresta Nacional de Chapecó, Santa Catarina, Brazil.

Submitted by **CARMEN SILVIA BUSIN** (e-mail: carmen@upf.br), **NOELI ZANELLA, SAMARA ARSEGO GUARAGNI, ALMIR DE PAULA,** and **MARIA CRISTINA KURTZ DE LIMA,** Instituto de Ciências Biológicas, Universidade de Passo Fundo, Campus I, Bairro São José, Passo Fundo, Rio Grande do Sul, 99001-970, Brazil.

XENOPUS RUWENZORIENSIS (Ruwenzori Clawed Frog). DEMOCRATIC REPUBLIC OF THE CONGO: NORTH KIVU: Ndjuma [= Djuma], Virunga National Park, Northern Sector (00.4919ºN, 29.4701ºE; WGS 84; 1174 m elev.). 9–10 July 2008. E. Greenbaum, C. Kusamba, M. M. Aristote, and W. M. Moniga. Laboratory of Environmental Biology, University of Texas at El Paso (UTEP 20008–09). ORIENTALE: Mayimbili, near Epulu (01.2382ºN, 28.3515ºE; WGS 84; 742 m elev.). 18 July 2009. E. Greenbaum, C. Kusamba, M. M. Aristote, and W. M. Moniga. (UTEP 20010). Verified by Ben Evans. First country record (Tinsley and Kobel 1996. The Biology of *Xenopus*. Clarendon Press, Oxford, United Kingdom. xxii + 440 pp.). Verification supported with mitochondrial data from 12S and 16S ribosomal DNA, transfer RNAVal, and the cytochrome c oxidase subunit I (CO1) gene, and nuclear data from the RAG1 gene (Evans, Greenbaum, Kusamba and colleagues, unpubl. data). Species described from lowland rainforest at Bundibugyo in Semliki Valley, Uganda, at foothills of Ruwenzori Mountains. New localities extend range ca. 45 km west (Ndjuma) and 180 km northwest (Mayimbili) from type locality.

Submitted by **ELI GREENBAUM**, Department of Biological Sciences, University of Texas at El Paso, El Paso, Texas 79968,

USA (e-mail: egreenbaum2@utep.edu); and **CHIFUNDERA KUSAMBA**, Laboratoire d'Herpétologie, Département de Biologie, Centre de Recherche en Sciences Naturelles, Lwiro, République Démocratique du Congo (e-mail: chifundera@yahoo.co.uk).

TESTUDINES — TURTLES

KINOSTERNON SUBRUBRUM (Mississippi Mud Turtle). USA: ARKANSAS: Logan Co.: ~5 km N of Magazine, AOR crossing AR 109 (35.1845°N, 93.8047°W; WGS 84). 05 April 2009. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 31319). New county record. Hand captured adult. Fills a distributional hiatus between previous records in Franklin, Johnson, Yell, and Scott counties in west-central Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MATTHEW B. CONNIOR,** Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467, USA; e-mail: mconnior@astate.edu.

KINOSTERNON SUBRUBRUM HIPPOCREPIS (Mississippi Mud Turtle). USA: ARKANSAS: Lee Co.: near Lee County Wildlife Management Area 3.4 miles E Haynes (34.89067ºN, 90.73201ºW; WGS84; elev. 73 m). 31 May 2010. Thomas J. Belford. University of Kansas Natural History Museum (KUDA 012137–012138). Verified by William E. Duellman. First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.). Extends range 22.4 km from nearest known record from St. Francis Co. Single specimen was found crossing AR 131 mid-morning.

Submitted by **THOMAS J. BELFORD**, 701 W Academy Avenue, Searcy, Arkansas 72143, USA; e-mail: thomasbelfordiniraq@yahoo.com.

PELODISCUS SINENSIS (Chinese Soft-shelled Turtle). PHILIPPINES: MINDANAO PROVINCE: South Cotabato; Municipality: Tupi (6.200939°N, 124.563437°E; no datum available). 19 March 2010. Pierre Fidenci. California Academy of Sciences photo voucher (CAS-HPV 63). Verified by Jérome Maran. First confirmed record for South Cotabato (Diesmos et al. 2008. Chelon. Cons. Biol. 7:157–177), and ca. 500 km from only record in Mindanao. Adult observed at fish pond within city limits of Tupi.

Submitted by **PIERRE FIDENCI,** Endangered Species International, 77 Brady St., San Francisco, California 94108, USA; e-mail: pfidenci@endangeredspeciesinternational.org.

STERNOTHERUS MINOR PELTIFER (Stripe-necked Musk Turtle). USA: ALABAMA: Chilton Co.: 7.4 km S of CR 25 on CR 73 (33.01586°N, 87.52242°W; WGS84). 01 March 2009. J. Burling and J. Wicknick. University of Montevallo Collection of Vertebrates (UMCV-RT0021). Verified by Joseph R. Mendelson III. Two males (8.4, 7.5 cm straight-line carapace length) and one female (8.4 cm). First county record; fills a gap among Shelby, Bibb, Perry, Coosa, and Elmore counties (Mount 1975. The Reptiles and Amphibians of Alabama. University of Alabama Press, Tuscaloosa. 347 pp. We also searched *Herpetological Review* records from 1967–March 2010 and all museums on www.herpnet.org).

Collection was made under the authority of Alabama Department of Conservation and Natural Resources collecting permit # 4784 (JAW).

Submitted by **JOHN W. BURLING**[1] and **JILL A. WICKNICK**[2], Departments of Psychology[1] and Biology[2], University of Montevallo, Montevallo, Alabama 35115, USA; e-mail: wicknickja@montevallo.edu.

STERNOTHERUS ODORATUS (Eastern Musk Turtle). USA: TENNESSEE: Chester Co.: Henderson, Freed-Hardeman University (35.4387°N, 88.6338°W; WGS84). 16 October 2009. Benjamin M. Reese, Jared Symonds, Lamont Otey, Tiffany N. Odom, Sequina Robinson, and David Tidwell. Verified by A. Floyd Scott. Austin Peay State University's David H. Snyder Museum of Zoology (APSU 19007 color photo). First record for county (Scott and Redmond 2008. Atlas of Reptiles in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available from http://www.apsu.edu/reptatlas; accessed 09 February 2010). Specimen was collected from one of FHU's research ponds using a mesh hoop net baited with sardines. The pond is surrounded by dense hardwoods and boarders a swamp. Voucher collected under Tennessee Wildlife Resources Agency Permit 1494.

Submitted by **BENJAMIN M. REESE** (e-mail: ben.reese@students.fhu.edu), **JARED SYMONDS**, **LAMONT OTEY**, **TIFFANY N. ODOM**, **DAVID TIDWELL**, **SEQUINA ROBINSON**, and **BRIAN P. BUTTERFIELD**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340, USA (e-mail: bbutterfield@fhu.edu).

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: INDIANA: Pike Co.: Patoka River National Wildlife Refuge and Management Area (38.35046ºN, 87.12078ºW; NAD 83). 16 April 2009. Sarabeth Klueh, Angela Garcia, and Alisha Maves. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2009ai). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii–404 pp.) Adult male caught in hoop trap.

Submitted by **SARABETH KLUEH** (e-mail: sklueh@dnr.in.gov) and **ANGELA GARCIA**, Wildlife Diversity Section, Indiana Department of Natural Resources Division of Fish and Wildlife, 553 E. Miller Drive, Bloomington, Indiana 47401, USA; **ALISHA MAVES** and **LINDSEY LANDOWSKI** (e-mail: Lindsey_Landowski@fws.gov), US Fish and Wildlife Service, Patoka River National Wildlife Refuge, 510 1/2 West Morton Street, P.O. Box 217, Oakland City, Indiana 47660, USA.

TRACHEMYS SCRIPTA SCRIPTA (Yellow-bellied Slider). USA: GEORGIA: Wilkes Co.: Tignall, Jane Hill Road, 0.48 km NE Newtown Road (33.83098°N, 82.80704°W; WGS84; elev. 5 m). 29 April 2010. Justin T. Oguni. Verified by Kenneth L. Krysko. Florida Museum of Natural History (photographic voucher UF 157776). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575

pp.). Observed basking on a log in a wetland surrounded mostly by mixed hardwood forest at 1723 h.

Submitted by **JUSTIN T. OGUNI**, College of Veterinary Medicine, University of Georgia, Athens, Georgia 30602, USA; e-mail: goonie16@gmail.com.

SQUAMATA — LIZARDS

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: ALABAMA: Tuscaloosa Co.: Northport, 3550 Watermelon Road (33.238706°N, 87.552747°W; WGS84). 25 September 2009. Christopher Thawley. University of Alabama Herpetological Collection (UAHC 16363). Verified by Kenneth L. Krysko. New county record (Mount 1975. Amphibians and Reptiles of Alabama. Auburn University Agricultural Experiment Station, Auburn, Alabama. 347 pp.). The nearest known record is from Jefferson Co., Alabama (Marion and Bosworth 1982. Herpetol. Rev. 13:52) 74 km NE. Juvenile, captured by hand, observed along with two adults, suggesting presence of potential breeding population. Anecdotal reports place additional populations in some dormitories on the University of Alabama main campus in Tuscaloosa, less than 3 km S and in Cottondale, ca. 10 km SE.

Submitted by **CHRISTOPHER J. THAWLEY**, Department of Biological Sciences, University of Alabama, Box 870345, Tuscaloosa, Alabama 35487, USA; e-mail: cjthawley@crimson.ua.edu.

LEIOCEPHALUS CARINATUS (Northern Curly-tailed Lizard). USA: FLORIDA: St. Lucie Co.: Port Saint Lucie, SW Biltmore Street & SW Molloy Street (27.28645°N, 80.36385°W, WGS84; elev. 5 m). 04 April 2010. Kenneth L. Krysko, Steve A. Johnson, Kyle E. Giddens, Kurt H. Gielow, Travis S. Lowke, William M. Moore, Eric Suarez, Cailey D. Thomas. Verified by Kevin M. Enge. Florida Museum of Natural History (UF 157453). New county record and extends the range ca. 44 km northwest of the closest known verified locality in Martin Co. (Hauge and Butterfield 2000. Herpetol. Rev. 31:53).

Submitted by **KENNETH L. KRYSKO** (e-mail: kenneyk@flmnh.ufl.edu), **KYLE E. GIDDENS, KURT H. GIELOW, TRAVIS S. LOWKE, WILLIAM M. MOORE, ERIC SUAREZ, CAILEY D. THOMAS**, Division of Herpetology, Florida Museum of Natural History, Dickinson Hall, University of Florida, Gainesville, Florida 32611, USA; and **STEVE A. OHPHISAURUS ATTENUATUS ATTENUATUS (Western Slender Glass Lizard). USA: TEXAS: Tyler Co.: Big Thicket National Preserve, Turkey Creek Unit (30.58471ºN, 94.33588ºW; WGS 84). 28 November 2008. P. Crump, R. Rommel, and H. Pate. Verified by Carl Franklin. University of Texas Arlington UTADC 4015 – 4017. New county record (Dixon, J.R., 2000. Amphibians and Reptiles of Texas. 2nd ed. TAMU Press, College Station, Texas. 432 pp.).

Submitted by **PAUL CRUMP** (e–mail: pcrump@houstonzoo.org), **RACHEL ROMMEL** (e–mail: rrommel@houstonzoo.org), Department of Conservation and Science, Houston Zoo, 1513 North Macgregor Way, Houston, Texas 77030, USA; and **HAIGLER PATE**, National Park Service, Big Thicket National Preserve, 6044 FM 420, Kountze, Texas 77625, USA (e-mail: Haigler_Pate@nps.gov).

PLESTIODON LATICEPS (Broad-headed Skink). USA: ARKANSAS: Ouachita Co.: ~23 km W of Camden (33.584058°N, 93.085246°W; WGS 84). AOR on Ouachita Co. Rd. 76, 1.5 km W Junction Co. Rd. 76/AR 57. 29 May 2010. K. Roberts and M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (photo voucher ASUMZ 31528). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.). The species has also been collected from neighboring Columbia and Union counties in southern Arkansas.

Submitted by **MATTHEW B. CONNIOR**, Health and Natural Sciences, South Arkansas Community College, 300 S. West Avenue, El Dorado, Arkansas 71730, USA (e-mail: mconnior@southark.edu); **KORY ROBERTS**, Rogers High School, 2300 South Dixieland Road, Rogers, Arkansas 72758, USA; and **IDUN GUENTHER**, Fisheries and Wildlife Biology, Arkansas Tech University, Russellville, Arkansas 72801, USA.

SQUAMATA — SNAKES

AGKISTRODON CONTORTRIX MOKASEN (Northern Copperhead). USA: GEORGIA: Whitfield Co.: Heritage Point Park (34.7942972ºN, 84.9445944ºW; no datum available). 19 May 2010. Chris Manis and John Patrick. Verified by John Jensen. University of Tennessee at Chattanooga Museum of Natural History (UTC Digital Collection 4667TPW-GMU). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 570 pp.) Specimen was found in an open fairway of a canopied disc golf course.

Submitted by **CHRIS MANIS** and **THOMAS P. WILSON**, Department of Biological and Environmental Sciences, University of Tennessee at Chattanooga, 215 Holt Hall, Department 2653, 615 McCallie Avenue, Chattanooga, Tennessee 37403, USA; and **JOHN PATRICK**, Dalton Middle School, 1250 Cross Plains Trail, Dalton, Georgia 30721, USA.

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). USA: TENNESSEE: Lewis Co.: Buffalo River, 6.3 km downstream from Natchez Trace Parkway (35.4687°N, 87.5027°W; NAD 83). 10 July 2008. Todd Crabtree and Dwayne Estes. David H. Snyder Museum of Zoology, Austin Peay State University (APSU 18924, 18925, color photos). Verified by Nathan Parker. New county record (Scott and Redmond. 2008 [latest update: 14 July 2008]. Atlas of Reptiles in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available from http://apsu.edu/reptatlas/ [accessed 23 July 2008]). Range extension of ca. 150 river km up the Buffalo River drainage from the nearest downstream record in Humphreys Co. Adult on log overhanging water and juvenile on lower ledge of shale bluff along river; sky overcast with light rain, 1346 h.

Submitted by **TODD CRABTREE,** Division of Natural

Areas, Tennessee Department of Environment and Conservation, Nashville, Tennessee 37243, USA; **DWAYNE ESTES** and **A. FLOYD SCOTT**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee, USA (e-mail: scotta@apsu.edu).

CEMOPHORA COCCINEA (Scarletsnake). USA: ARKANSAS: Ouachita Co.: ~25 km W of Camden; (33.566811°N, 93.094641°W; WGS 84). Under a board 1 km N jct Ouachita Co. Rd. 27 and Hwy 278. 29 May 2010. I. Guenther. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (photo voucher ASUMZ 31527). New county record. This species has also been collected from neighboring Columbia and Union counties in southern Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MATTHEW B. CONNIOR**, Health and Natural Sciences, South Arkansas Community College, 300 S. West Avenue, El Dorado, Arkansas 71730, USA (e-mail: mconnior@southark.edu); **KORY ROBERTS**, Rogers High School, 2300 South Dixieland Road, Rogers, Arkansas 72758, USA; and **IDUN GUENTHER**, Fisheries and Wildlife Biology, Arkansas Tech University, Russellville, Arkansas 72801, USA.

CLONOPHIS KIRTLANDII (Kirtland's Snake). USA: OHIO: Brown Co.: Washington Twp: 13413 Wardlow Road (39.0080°N, 83.8506°W; WGS 84). 20 September 2008. Todd Rosenhoffer. Verified by John W. Ferner and Jeffrey G. Davis. Cincinnati Museum Center Herpetology Collection (CMC HP 5222–5223 [digital files and prints]). New county record (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contrib. No. 10, Columbus).

Submitted by **TODD ROSENHOFFER**, Greater Cincinnati Herpetological Society, P.O. Box 14783, Cincinnati, Ohio 45250, USA (e-mail: trosenhoffer@msn.com); and **PAUL J. KRUSLING**, Geier Collections and Research Center, Cincinnati Museum Center, 1301 Western Avenue, Cincinnati, Ohio 45203, USA (e-mail: pkrusling@gmail.com).

COLUBER (=MASTICOPHIS) FLAGELLUM FLAGELLUM (Eastern Coachwhip). USA: ARKANSAS: Ouachita Co.: near White Oak Lake State Park 5.9 miles S Bluff City (33.68647ºN, 93.09792ºW; WGS84; elev. 82 m). 15 Apr 2010. Thomas J. Belford. University of Kansas Natural History Museum (KUDA 911879). Verified by William E. Duellman. First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.). Single specimen was found on the forest floor along a woodland trail.

Submitted by **THOMAS J. BELFORD**, 701 W Academy Avenue, Searcy, Arkansas 72143, USA; e-mail:thomasbelfordiniraq@yahoo.com.

CONIOPHANES IMPERIALIS IMPERIALIS (Tamaulipan Black-striped Snake) USA: TEXAS: Starr Co.: approximately 7 km NNE of Roma, along N. Ebony Ave. (26.46343°N, 98.98797°W; WGS 84). 27 March 2010. Gilbert Martinez Jr. and Edwin Quintero. Verified by Frank W. Judd. University of Texas – Pan American Vertebrate Museum (UTPA 03101, photographic voucher). First county record. Westernmost record in the United States, ca. 70 km WNW of the nearest published record. Previously reported in adjacent Hidalgo Co. (Dixon 2000. Amphibians and Reptiles of Texas. 2nd ed. Univ. of Texas A&M Press, College Station. viii + 421 pp.; Werler and Dixon 2000. Texas Snakes: Identification, Distribution, and Natural History. University of Texas Press, Austin. xv + 437 pp.). Male (24.4 cm SVL, 32.0 cm TL) found under cardboard box on moist, loose soil. Nearby habitat was typical thorn scrub with tall grasses.

Submitted by **GILBERT MARTINEZ Jr., EDWIN QUINTERO, JOSÉ MANUEL CANTÚ MARTÍNEZ,** and **FREDERIC ZAIDAN III**, Department of Biology, University of Texas – Pan American, 1201 W. University Drive, Edinburg, Texas 78539, USA (e-mail: fzaidan@utpa.edu).

DIADOPHIS PUNCTATUS (Ring-necked Snake). USA: CALIFORNIA: Inyo Co.: Ninemile Canyon Rd, 0.5 rd mi. E of Inyo/Tulare Co. line (35.85645°N, 118.00072°W, WGS84; elev. 1848 m). 06 June 2010. D. Tobler. Verified by N. Camacho. Natural History Museum of Los Angeles County, LACM PC 1509 (photo voucher). Second record for Inyo Co. and first occurrence for eastern slope of Sierra Nevada. Nearest records are for Death Valley National Monument, 143 airline km NE of this record (Emmerich and Cunningham 2003. Herpetol. Rev. 34:169), and Kern River Canyon at Cow Flat Creek (MVZ 56716, 59979), 74 airline km to the SW. Present specimen was an adult male encountered AOR at 1650 h. This species has remained undetected until now despite long-running (1982–2010) herpetofaunal surveys in this canyon (RWH and colleagues, unpubl. data).

Submitted by **ROBERT W. HANSEN**, 16333 Deer Path Lane, Clovis, California 93619, USA (e-mail: herpreview@gmail.com); and **DAVID TOBLER**, Fresno Chaffee Zoo, 894 West Belmont Avenue, Fresno, California 93728, USA (e-mail: dtobler@fresnochaffeezoo.com).

DIADOPHIS PUNCTATUS (Ring-necked Snake). USA: WASHINGTON: Whitman Co.: Wawawai Grade Rd, 3.2 km E of Wawawai County Park (46.6211667ºN, 117.3335333ºW; WGS 84, 460 m elev.). 23 May 2009. Edward A. Myers and Kari Maupin. Verified by Hugo Alamillo. Charles R. Conner Museum (CRCM-09-84), School of Biological Sciences, Washington State University. Adult female collected DOR (48.9 cm SVL and 15.4 g). First documented specimen in 71 years. Some regional field guides indicate *Diadophis punctatus* as being fairly common in southeastern Whitman Co. (Nussbaum et. al., 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. of Idaho Press, Moscow. 367 pp.). However, no individuals have been documented with either photo or specimen vouchers in this region of Washington state since the 1930s (Svihla 1938. Copeia 1938:47).

Submitted by **EDWARD A. MYERS,** School of Biological Sciences, Washington State University, Pullman, Washington 99164, USA (e-mail: edward_myers@wsu.edu); **KARI A. MAUPIN,** 1510 NW Turner Dr. #5, Pullman, Washington 99163, USA (e-mail: kari_maupin@yahoo.com); and **ROBERT E. FARANCIA ABACURA ABACURA (Eastern Mudsnake). USA: ALABAMA: Elmore Co.: Hwy 14 near the town of Elmore (32.541900°N, 86.310283°W; WGS84/NAD83). 5 May 2010. R. Birkhead. DOR. AUM 38652. Verified by Craig Guyer. New county record. *Farancia a. abacura* has been previously documented to the south in Montgomery Co., to the southeast in Macon Co., and to the west in Autuaga Co. (Mount 1996. The Amphibians and Reptiles of Alabama. University of Alabama Press, Auburn. xi + 347 pp.). A warm, heavy rain occurred two days prior to finding this specimen.

Submitted by **ROGER D. BIRKHEAD**, Alabama Science In Motion, Auburn University, Alabama 36849-5414, USA; e-mail: birkhrd@auburn.edu.

LAMPROPELTIS GETULA HOLBROOKI (Speckled Kingsnake). USA: ARKANSAS: Pope Co.: 11.3 km S Ben Hur off St. Hwy. 16 (34.290126°N, 94.072151°W; WGS 84). 22 April 2010. C. T. McAllister. Verified by R. Tumlison. Henderson State University Herpetological Collection (HSU 1516). New county record filling a distributional hiatus among Johnson (Robison and McAllister. 2008. Herpetol. Rev. 39:244–245) and Van Buren counties (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). This snake has now been documented from 74 of 75 Arkansas counties; only Grant Co. remains.

Submitted by **CHRIS T. McALLISTER**, RapidWrite, 102 Brown Street, Hot Springs National Park, Arkansas 71913, USA (e-mail:drctmcallister@aol.com); and **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

LAMPROPELTIS TRIANGULUM (Milksnake). USA: ALABAMA: Marshall Co.: Collected near Union Grove ca. 2.71 km SW of the Tennessee River. 18 May 2005. Raymond N. Little and Carmen Barnard. Auburn University Museum AHAP-D 274. Verified by George Cline. First county record. Male was observed and captured in leaf litter at the base of a limestone rock outcropping at ca. 0915 h. Rock outcropping was located in a power line cut. This specimen helps fill a distribution gap for this species in north-central Alabama.

Submitted by **RAYMOND N. LITTLE**, P.O. Box 5013, Everglades City, Florida 34139, USA; e-mail: Raymond_Little@nps.gov.

LAMPROPELTIS TRIANGULUM GENTILIS (Central Plains Milksnake). USA: KANSAS: Norton Co.: Hwy 36, 1.3 rd mi. E of Rd E7 (39.8298417°N, 99.7354278°W; WGS84; elev. 2281 ft.). A second specimen was located at 39.8297389°N, 99.7349556°W. 04 May 2010. Brian Hinds. University of Texas at Arlington photo vouchers (UTADC 6721, 6722). Verified by J. W. Streicher. New county record (http://webcat.fhsu.edu/ksfauna/herps/index.asp?page=kansas). Snakes were found under rocks in an area of prairie grass and sandstone rock ridges (habitat photo UTADC 6723). I thank Brian Hubbs for confirming the absence of previous records for Norton Co.

Submitted by **BRIAN HINDS,** 14530 Mulberry Drive, Whittier, California 90604, USA; e-mail: fundad@kingsnake.org.

LAMPROPELTIS TRIANGULUM SYSPILA (Red Milksnake). USA: ARKANSAS: Searcy Co.: vic. Mull, ~3 km S of jct AR 14/ Ramblewood Trail (36.052048°N, 92.594601°W; WGS 84). 21 May 2010. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 31524). First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.). Hand caputured male (SVL 164 mm). Species has also been collected from neighboring Marion and Stone counties in northern Arkansas.

Submitted by **MATTHEW B. CONNIOR,** Health and Natural Sciences, South Arkansas Community College, 300 S. West Avenue, El Dorado, Arkansas 71730, USA; e-mail: mconnior@southark.edu.

LICHANURA TRIVIRGATA ROSEOFUSCA (Coastal Rosy Boa). USA: CALIFORNIA: Los Angeles Co.: Sierra Pelona, Lake Hughes Rd, ca. 17.6 km by air NNE of jct with Interstate

5 (34.5844444°N, 118.5602778°W; datum WGS84), 555 m elev. 3 June 2010. DOR male. J. Lauermann and Z. West. A second specimen (adult female) was found on 5 June 2010, ca. 1.2 km by air NNW from the first locality (34.5941667°N, 118.5638889°W), 585 m elev. J. Lauermann and D. Lawrence. Verified by N. Camacho. Los Angeles County Museum photo vouchers (LACM PC 1505, 1506). These are the first records for the Sierra Pelona and help define the distribution of this species along the northwestern edge of the range. SDNHM 5563 (collected by F. E. Walker in 1931), listed as having been obtained in Castaic (presumably from the hills near that city), lies ca. 12 km by air SSW from LACM PC 1505. Habitat at the Sierra Pelona collection sites is chaparral vegetation with numerous rock outcrops and talus.

Submitted by **ZACK WEST**, 12507 Appleton Way, Los Angeles, California 90066, USA (e-mail: ectoredexotics@gmail.com); and **JOHN LAUERMANN**, 28002 Woodstock Ave, Castaic, California 91384, USA (e-mail: ricrabt@aol.com).

NERODIA RHOMBIFER (Diamond-backed Watersnake). USA: ALABAMA: Limestone Co.: Intersection of Harris Station Rd. and Lucas Ferry Rd. (34.68862°N, 87.00095°W; WGS 84). 12 May 2010. R. King. AUM 38893. Verified by Craig Guyer and Harry W. Greene. New county record (Mount 1975. Amphibians and Reptiles of Alabama. Auburn Printing Co., Auburn. 347 pp.). First record from the Tennessee River drainage in Alabama (Gibbons and Dorcas 2004. North American Watersnakes: A Natural History. University of Oklahoma Press, Norman. 438 pp.), and extends its range ca. 150 km NE from the nearest Alabama locality (Tuscaloosa Co.), and ca. 100 km SE from the nearest Tennessee River drainage locality (Hardin Co., Tennessee).

We thank C. Guyer and H. W. Greene for verifying this record. S. Graham is supported in part by NIH grant R01-A149724 to T. Unnasch.

Submitted by **SEAN P. GRAHAM**, Auburn University Department of Biological Sciences, 331 Funchess Hall, Auburn, Alabama 36849, USA (e-mail: grahasp@auburn.edu); **ERIC C. SOEHREN,** Alabama Department of Conservation and Natural Resources, State Lands Division, 64 North Union Street, Montgomery, Alabama 36130, USA; and **RITCHIE L. KING**, 1004 7th Ave., Athens, Alabama 35611, USA.

OPHRYACUS UNDULATUS (Mexican Horned Pitviper). MÉXICO: PUEBLA: Municipality of Tlatlauquitepec: Xocayucan (19.53479°N, 97.28437°W, estimated from map, 1493 m elev.). 27 May 2005. Israel Solano Zavaleta. Verified by Edmundo Pérez Ramos. Colección Herpetológica del Museo de Zoología Alfonso L. Herrera, UNAM (MZFC 17663). New municipality record. Second record for Puebla, and a state range extension of 180 km SE of Coyomeapan (Canseco-Márquez et al. 2000. Herpetol. Rev. 31:259–263) and an extension of 93 km NW of Tenango de Doria, Hidalgo (Flores-Villela et al. 1992. Texas J. Sci. 44:249–250) and 92.5 km SE of Pico de Orizaba, Veracruz (Pérez-Higareda and Smith 1999. Inst. Biol. Publ. Espec. [7]:1–122. The snake was found in pine forest.

Submitted by **ISRAEL SOLANO-ZAVALETA** (e-mail: crotalus.viper@gmail.com)**, ANDRÉS ALBERTO MENDOZA-HERNÁNDEZ** (e-mail: andreasmeher@gmail.com), and **LUIS CANSECO-MÁRQUEZ,** Museo de Zoología, Facultad de Ciencias, UNAM, A. P. 70-399, México D. F. 04510, México (e-mail: lcanseco@gmail.com).

OXYRHOPUS LEUCOMELAS. VENEZUELA: ESTADO TÁCHIRA: Las Delicias, Municipio Rafael Urdaneta, northeastern versant of the Cordillera Oriental de Colombia (07.0056666ºN, 72.4388333ºW; SAD 69, elev. 1688 m). 12 March 2010. D. Calcaño. Colección de Vertebrados, Universidad de los Andes, Mérida, estado Mérida (CVULA 7499). Verified by E. Smith and W. Lamar. First country record and northernmost for the species. Its occurrence in Venezuela was expected as there is a close report from Departamento Norte de Santander between Arboledas and Salazar (Pérez-Santos and Moreno 1988. Ofidios de Colombia. Museo Regionale de Science Naturali Torino. 517 pp.; Lynch 2009. Papeis Avulsos Zool. 49:319–337) at ca. 26 km SW from the locality reported herein. *Oxyrhopus leucomelas* remains a rare species only known from a few specimens in Colombia (Lynch 2009, *op. cit.*), Peru, and Ecuador (http://www.jcvi.org/reptiles/species.php?genus=Oxyrhopus&species=leucomelas; accessed 13 March 2010).

Submitted by **DANIEL CALCAÑO,** Serpentario los Llanos, Avda Intercomunal 13, Barinitas, 5206 Barinas, Venezuela (e-mail: serpentariolosllanos@hotmail.com); and **CÉSAR L. BARRIO-AMORÓS,** Fundación Andígena, Apartado 210, Mérida 5101-A, Venezuela (e-mail: cesarlba@yahoo.com).

OXYRHOPUS PETOLA (Calico False Coral Snake). BRAZIL: DISTRITO FEDERAL: Brasília municipality: Parque Nacional de Brasília (15.594167ºS, 48.029722º; SAD 69). 10 February 2008. T. Barros. Coleção Herpetológica da Universidade de Brasília (CHUNB 51437). Verified by G. Colli. New state record. This widely distributed species is found from Mexico to northeast Argentina (Peters and Orejas-Miranda 1986. Catalogue of the Neotropical Squamata. Part I – Snakes, 2nd ed. Smithsonian Inst. Press, Washington. 174 pp.). It principally inhabits forest habitats of Amazonia and Atlantic Forest (Jorge da Silva and Sites 1995. Conserv. Biol. 9 [4]:873–901; Pontes and Rocha 2008. Serpentes da Serra do Mendanha, RJ. Technical Books Ed. 147 pp.). There are sparse records from Brazilian Cerrado (Strussmann 2000. *In* C. J. R. Alho et al. [ed.], Fauna Silvestre da Região do Rio Manso MT, pp. 153–189. IBAMA; Valdujo and Nogueira 2001. Herpetol. Rev. 32:128–130; Vaz-Silva et al. 2007. Checklist 3 [4]:338–345). Extends the known distribution ca. 470 km NE of the nearest locality, Espora Hydroeletric Power Plant, GO (Vaz-Silva et al. 2007, *op. cit.*) and increases the number of snake species known from the Distrito Federal to 62 (França et al. 2008. Copeia 2008:20–36).

PANTHEROPHIS GUTTATUS (Red Cornsnake). USA: TENNESSEE: Rutherford Co.: Hwy 70S, (35.808208ºN, 86.187722ºW; NAD83). 14 May 2010. Brian T. Miller. Verified

by M. L. Niemiller. Herpetology Collection at Middle Tennessee State University (MTSU 182S). First record for county. (Scott and Redmond 2008 [latest update: 18 February 2010]. Atlas of Reptiles in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. http://apsu.edu/reptatlas/(accessed 10 June 2010). Adult female found DOR ca. 12 km NW of Cannon Co. record which decreases the size of the hiatus in records for middle Tennessee (Miller and Miller 1993. Herpetol. Rev. 24:156).

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA (e-mail: bmiller@mtsu.edu); and **JOYCE L. MILLER**, MIMIC, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA (e-mail: jlmiller@mtsu.edu).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blindsnake). USA: FLORIDA: Escambia Co.: 9933 Hillview Road, Pensacola (30.54027°N, 87.22084°W; WGS84; elev. 15 m). 18 May 2010. Elizabeth Barber. Florida Museum of Natural History (UF 157774 photographic voucher). New county record. Extends the range ca. 290 km W of the closest known verified locality in Leon Co. (UF 140540–41; Krysko et al. 2005. Herpetol. Rev. 36:85–87).

Submitted by **KENNETH L. KRYSKO**, Division of Herpetology, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA (e-mail: kenneyk@flmnh.ufl.edu); and **MELVIN P. GRAMKE,** Division of Herpetology, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA (e-mail: gramkem@ufl.edu).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blindsnake). USA: FLORIDA: St. Lucie Co.: Port Saint Lucie, Southwest Biltmore Street, 0.24 km N of Sea Holly Terrace (27.29151°N, 80.36685°W; WGS84; elev. 5 m). 04 April 2010. Kenneth L. Krysko, Steve A. Johnson, Kyle E. Giddens, Kurt H. Gielow, Travis S. Lowke, William M. Moore, Eric Suarez, Cailey D. Thomas. Verified by Kevin M. Enge. Florida Museum of Natural History (UF 157451). New county record. Extends the range ca. 68 km NW of the closest known verified locality in Palm Beach Co. (UF 101766; also see Delorey and Mushinsky 1987. Herpetol. Rev. 18:56).

Submitted by **KENNETH L. KRYSKO** (e-mail: kenneyk@flmnh.ufl.edu), **KYLE E. GIDDENS, KURT H. GIELOW, TRAVIS S. LOWKE, WILLIAM M. MOORE, ERIC SUAREZ, CAILEY D. JOHNSON**, Gulf Coast REC-Plant City Center and Department of Wildlife Ecology & Conservation, 1200 N. Park Road, Plant City, Florida 33563, USA.

SIBON ANNULATUS (Ringed Snail Sucker). COLOMBIA: CESAR: San Martín: Alto de La Paz (7.956254°N, 73.348031°W; WGS84; 1402 m elev.). 21 February 2009. R. Moreno-Arias. Colección de reptiles Instituto de Ciencias Naturales-Universidad Nacional de Colombia, Bogotá D.C, Cundinamarca, Colombia (ICN 12020). Verified by J. E. Carvajal-Cogollo. First record from South America and Colombia. This Central Amerian snake was known from Atlantic premontane slopes and lowlands of Honduras, Nicaragua, Costa Rica, and Panamá (Savage and McDiarmid 1992. Copeia 1992:421–432; http://www.jcvi.org/reptiles/species.php?genus=Sibon&species=annulatus). Extends known range to "Cordillera Oriental" in Colombia ca. 500 km W from nearest locality (Darién, Panamá; Savage and McDiarmid, *op. cit.*).

Submitted by **RAFAEL MORENO-ARIAS,** Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Apartado Aéreo 55187, Bogotá D.C. Colombia; e-mail: rafamorearias@gmail.com.

TANTILLA GRACILIS (Flat-headed Snake). USA: ARKANSAS: Howard Co.: 2.4 km W of Umpire off St. Hwy. 278 (34.290126°N, 94.072151°W; WGS 84). 23 March 2006. H. W. Robison. Verified by R. Tumlison. Henderson State University Herpetological Collection (HSU 1520). New county record. Partially fills a distributional hiatus among Polk and Sevier counties (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

Submitted by **CHRIS T. McALLISTER**, RapidWrite, 102 Brown Street, Hot Springs National Park, Arkansas 71913, USA (e-mail:drctmcallister@aol.com); **CHRISTA BRUMMETT** and **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas, 71754, USA (e-mail: hwrobison@yahoo.com).

TANTILLA OOLITICA (Rim Rock Crowned Snake) USA: FLORIDA: Monroe Co.: Big Pine Key (24.680°N, 81.352°W; NAD 83). 18 December 2007. Michael A. Yirka, Joseph N. Flowers, Michael D. Martin, Kevin R. Messenger, and Nathan A. Shepard. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF photograph 152546). Island record. Extends the range 26.7 km W of the closest known locality on Vaca Key (Krysko and Decker 1996. Herpetol. Rev. 27:215.). Only known Lower Keys record outside of questionable Key West specimen (Telford 1966. Bull. Florida St. Mus. Biol. Ser. 10:261–304). Specimen was found under artificial cover in an upland hardwood hammock 0.28 km from the ocean.

Submitted by **MICHAEL A. YIRKA**, 6016 Countryview Lane, Raleigh, North Carolina 27606, USA; **JOSEPH N. FLOWERS**, 66 Lyon Drive, Sparta, North Carolina 28675, USA; **MICHAEL D. MARTIN**, University of South Carolina, Department of Biological Sciences, Coker Life Sciences Room 706, Columbia, South Carolina 29208, USA; **KEVIN R. MESSENGER** and **NATHAN A. SHEPARD,** Marshall University, Department of Biological Sciences, One John Marshall Drive, Huntington, West Virginia 25703, USA.

THAMNOPHIS PROXIMUS (Western Ribbonsnake). USA: ARKANSAS: Nevada Co.: ~8 km S of Bluff City (33.648175°N, 93.115576°W; WGS 84), AOR Nevada Co. Rd. 447. 30 May 2010. K. Roberts and M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (photo voucher ASUMZ 31526). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421pp.).This species

has also been collected from neighboring Calhoun, Columbia, and Union counties in southern Arkansas.

Submitted by **MATTHEW B. CONNIOR,** Health and Natural Sciences, South Arkansas Community College, 300 S. West Avenue, El Dorado, Arkansas 71730, USA (e-mail: mconnior@southark.edu); and **KORY ROBERTS**, Rogers High School, 2300 South Dixieland Road, Rogers, Arkansas 72758.

THAMNOPHIS RADIX (Plains Gartersnake). USA: MINNESOTA: Nicollet Co.: Minnesota Hwy 99 ca. 4.15 km E of Nicollet (44.282455°N, 94.135587°W; WGS 84). 3 April 2010. Found DOR, photographic records were deposited in the James Ford Bell Museum (JFBM P355a –c). Verified by Kenneth H. Kozak and Amy M. Luxbacher. Updated county record. Oldfield and Moriarty (1994. Amphibians & Reptiles Native to Minnesota. University of Minnesota Press, Minneapolis. 237 pp.) list a vouchered record dated pre-1960. A single specimen collected in Nicollet Co. in 1939 is the only other specimen from this county accessioned at the James Ford Bell Museum.

Submitted by **NOAH T. MARTYN,** 1218 Oak Street, New Ulm, Minnesota 56073, USA (e-mail: Noah.Martyn@gmail.com); and **CHRISTOPHER E. SMITH**, Wildlife Research & Consulting Services, LLC, 348 Bankers Drive, Saint Paul, Minnesota 55127, USA (e-mail: Christopher.Smith@WildlifeRCS.com).

THAMNOPHIS RADIX (Plains Gartersnake). USA: MINNESOTA: Olmsted Co.: County Hwy 19 ca. 12 km SE of jct I-90 (43.906580°N, 92.257339°W; WGS 84). 12 June 2009. Photographic records were deposited in the James Ford Bell Museum (JFBM P354a – d). Verified by Kenneth H. Kozak and Amy M. Luxbacher. New county record and the first vouchered specimen for Olmsted Co. (Oldfield and Moriarty 1994. Amphibians & Reptiles Native to Minnesota. University of Minnesota Press, Minneapolis. 237 pp.). Found by flipping rocks along highway.

Due to an earlier bioblitz competition's success at documenting new county records in the Talladega Uplands of Georgia in the spring of 2007 (Graham et al. 2007), we organized an additional contest in the same region during the following fall. To increase participant turnout and enthusiasm, the second bioblitz competition was touted as a rematch between the participants from Auburn University and the University of Georgia. As a result of this survey (mostly 5–7 October 2007), we documented 25 new county records (Jensen et al. 2008), surpassing the first competition's total. Severe drought conditions appeared to increase our success, as amphibians and reptiles were frequently found under moist cover objects at drying bodies of water. Localities were recorded using handheld GPS units with datum settings of WGS 84 and confirmed using Google Earth. The results presented below illustrate how the spirit of competition can be exploited for quick and useful presence-absence surveys, and the utility of surveying during multiple seasons.

Unless otherwise noted, all records were verified by Craig Guyer. AHAP-D indicates digital photo vouchers, AUM indicates specimens collected.

Caudata — Salamanders

Desmognathus monticola (Seal Salamander). Paulding Co.: Collected along headwaters of Raccoon Cr. ~100 m W of US Hwy 278 (33.939672°N, 84.981411°W). 06 October 2007. S. Hoss and D. Steen. AUM 37566–37567. Verified by George Folkerts.

Eurycea guttolineata (Three-lined Salamander). Polk Co.: Collected in Sewell Cr. 10 m W of Barrett/Wilson Rd. bridge

(33.952913°N, 85.284356°W). 07 October 2007. D. McMoran. AUM 37569.

Notophthalmus viridescens (Eastern Newt). Heard Co.: Found AOR on Roosterville Rd. at Centralhatchee Cr. bridge (33.391166ºN, 85.175040°W). 04 October 2007. S. Graham. AHAP-D 44.

Anura – Frogs

Lithobates palustris (Pickerel Frog). Heard Co.: Collected DOR on Barr Farm Rd. E of Ephesus at Centralhatchee Cr. bridge (33.412723°N, 85.208393°W). 04 October 2007. S. Graham. AUM 37494. Haralson Co.: Found under rock along Watermill Cr. 50 m S of Watermill Cr./Coppermine Rd. bridge (33.854506°N, 85.085676°W). 06 October 2007. S. Graham and V. Johnson. AHAP-D 48.

Testudines – Turtles

Apalone spinifera (Spiny Softshell). Haralson Co.: Found in Lake Olympia, a small drying reservoir along State Rt. 120 at VFW Post 7402 ~ 4.8 km E of Buchanan (33.811200°N, 85.141821°W). 06 October 2007. S. Graham and V. Johnson. AHAP-D 55. Paulding Co.: Found along Raccoon Cr., 0.05 km N of intersection with Braswell Mountain Rd. (34.007853°N, 84.892615°W). 06 October 2007. S. Cox. APAP-D 43.

Chrysemys picta picta (Eastern Painted Turtle). Haralson Co.: Found in Lake Olympia (33.811200°N, 85.141821°W). 06 October 2007. S. Graham and V. Johnson. AHAP-D 54.

Pseudemys concinna (River Cooter). Haralson Co.: Found in Lake Olympia (33.811200°N, 85.141821°W). 06 October 2007. V. Johnson and S. Graham. AHAP-D 52–53.

Sternotherus odoratus (Eastern Musk Turtle). Heard Co.: Captured in crayfish trap in beaver marsh 50 m S of intersection of US Hwy 27 and State Rt. 34 (33.288574°N, 85.087331°W). 05 October 2007. S. Graham and V. Johnson. AHAP-D 49. Haralson Co.: Captured in crayfish trap in Lake Olympia (33.811200°N, 85.141821°W). 07 October 2007. S. Graham and V. Johnson. AHAP-D 56.

Trachemys scripta (Pond Slider). Haralson Co.: Shell collected in Lake Olympia (33.81120034°N, 85.14182165°W). 07 October 2007. S. Graham and V. Johnson. AHAP-D 57. Paulding Co.: Found in private farm pond to the east of power line cut, south of intersection with Braswell Mountain Rd. (34.007109°N, 84.890804°W). 06 October 2007. S. Cox, A. Durso, E. Susko. AHAP-D 89.

Squamata – Snakes

Agkistrodon contortrix (Copperhead). Heard Co.: Found DOR on Roosterville Rd. (33.387313°N, 85.171920°W). 04 October 2007. S. Graham. AHAP-D 45.

Coluber constrictor (North American Racer). Haralson Co.: Found DOR on Mt. View Rd. (33.888953°N, 85.146418°W). 07 October 2007. S. Graham and V. Johnson. AHAP-D 59. Polk Co.: Found AOR along logging road ~ 4.7 km N of Braswell (34.023600°N, 84.949600°W). 06 October 2007. K. Nelson. AHAP-D 84.

Lampropeltis getula getula (Eastern Kingsnake). Haralson Co.: Found DOR at intersection of State Rt. 120 and 113 (33.827837°N, 85.046283°W).06 October 2007. S. Graham and V. Johnson. AHAP-D 61–63.

Nerodia erythrogaster (Plain-bellied Watersnake). Paulding Co.: Found in dry creek bed of Right Prong Cr., ~ 1.77 km W of Corley Lake (34.022497°N, 84.945434°W). 06 October 2007. K. Nelson. AHAP-D 85.

Opheodrys aestivus (Rough Greensnake). Heard Co.: Found DOR on State Rt. 100, 0.3 km NW of Franklin (33.284879°N, 85.109545°W). 05 October 2007. S. Graham and V. Johnson. AHAP-D 50.

Pantherophis alleghaniensis (Eastern Ratsnake). Haralson Co.: Collected DOR on State Rt. 120 at mile marker 15 (33.816196°N, 85.108115°W). 06 October 2007. S. Graham and V. Johnson. AUM 37496. See comments under *Pantherophis spiloides*.

Pantherophis guttata (Red Cornsnake). Bartow Co.: Found DOR on Stamp Creek Rd., 1.6 km E of US Hwy 411 intersection (34.274876°N, 84.735115°W). 06 October 2007. S. Graham and V. Johnson. AHAP-D 59. Paulding Co. Collected DOR on US Hwy 278 at intersection with Hulseytown Rd. (33.914859°N, 84.917788°W). 07 October 2007. S. Graham and V. Johnson. AUM 37497. Polk Co.: Collected freshly shed skin from power line cut at intersection with dirt logging road ~ 5 km N of Braswell (34.026953°N, 84.958205°W). 06 October 2007. A. Durso. AHAP-D 81–82.

Pantherophis spiloides (Gray Ratsnake).: Haralson Co.: Collected DOR at intersection of US Hwy 27 and State Rt. 120 in Buchanan. 07 October 2007. D. McMoran. AUM 34795. The genetic affinities of the *E. alleghaniensis* and *E. spiloides* listed above were not determined; AUM 37496 has a color pattern consistent with the formerly recognized taxon *Elaphe obsoleta obsoleta*; AUM 37495 is an adult (> 150 cm SVL) with a color pattern consistent with the formerly recognized taxon *Elaphe obsoleta spiloides*. Both individuals were collected in the same county on the same highway ~6–7 km apart within the same 24 h period.

Thamnophis sirtalis sirtalis (Eastern Gartersnake). Haralson Co.: Found DOR on State Rt. 120, 1.6 km SW of Buchanan at intersection with Matt Dillion Rd. (33.786517°N, 85.209427°W). 07 October 2007. S. Graham and V. Johnson. AHAP-D 61–63.

Acknowledgments.— We thank C. Guyer and G. Folkerts for verifying these records and J. Jensen for his assistance with logistics. We dedicate this contribution to the late George Folkerts.

New County Records of Amphibians and Reptiles from the Northern Coastal Plain of South Carolina, USA

JEFFREY D. CAMPER
Department of Biology, Francis Marion University
Florence, South Carolina 29506, USA
e-mail: jcamper@fmarion.edu

The southern Atlantic Coastal Plain of North American is known for having a very high species richness of herpetofauna with approximately 100 native species (Conant and Collins 1991). A single study, at only one location, in the northern South Carolina Coastal Plain yielded 72 species of amphibians and reptiles (Leiden et al. 1999). As part of a larger project on the reptiles of the state of South Carolina, documentation of the fauna of this relatively poorly studied part of the state has been undertaken. Previous locality records for this region have been published by Broach and McMahan (2009), Camper (2001), Camper and Knowles (2007), Camper and Brooks (2005) and Camper and Cloninger (2005).

All specimens represent new county records. All specimens have been deposited in the Charleston Museum (CA, CR) or the Vertebrate Collection of the Campbell Museum of Natural History at Clemson University (CUSC). All specimens deposited in the Charleston Museum were verified by A. Sanders and those in the Clemson collection by S. Miller. Nomenclature and common names follow Crother (2008). Unless stated otherwise, all specimens were collected by the author. Locality coordinates are in decimal degrees in WGS 84.

Caudata – Salamanders

Siren lacertina (Greater Siren). DARLINGTON CO.: Back Swamp, Pee Dee Research and Education Center, 7 km N Florence. 19 October 1999. CA 4545. Caught in a funnel trap in permanent water at the edge of a swamp. FLORENCE CO.: Lynches River County Park, 11 km S Florence. 3 October 2008. CUSC 2611. Caught in a funnel trap in a flooded ditch in hardwood forest.

Anura – Frogs

Acris gryllus (Southern Cricket Frog). FLORENCE CO.: Woods Bay State Natural Area, 4 km W Olanta. CA 4561. One specimen taken along the edge of an artificial pond. WILLIAMSBURG CO.: Wee Tee State Forest, NW end of Wee Tee Lake, 12.5 km E St. Stephen. 29 March 2008. CUSC 2595.

Hyla gratiosa (Barking Treefrog). FLORENCE CO.: Lynches River County Park, 11 km S Florence. 11 September 2008. Caught in a funnel trap along a drift fence in pine barrens habitat. CUSC 2608

Pseudacris crucifer (Spring Peeper). DARLINGTON CO.: Pee Dee Research and Education Center, 7 km N Florence. 12 May 1999. CA 4553.

Testudines – Turtles

Apalone spinifera aspera (Gulf Coast Spiny Softshell). CHESTERFIELD CO.: Sand Hills State Forest, Woodduck Pond, 11 km SE Patrick. 29 October 2006. CR 2777. B. T. Camper and J. D. Camper. Ten ribs and four vertebrae found on the pond dam.

Chelydra serpentina serpentina (Eastern Snapping Turtle). DARLINGTON CO.: Pee Dee Research and Education Center, 7 km N Florence. 21 June 1999. CR 2713. MARLBORO CO.: Blenheim (34.40158°N, 79.64535°W). CR 2818. R. J. Brooks, J. E. Krebs, and J. D. Camper.

Clemmys guttata (Spotted Turtle). MARLBORO CO.: Blenheim, AOR on Highway 38. 18 April 2004. CR 2807. R. J. Brooks.

Kinosternon subrubrum subrubrum (Eastern Mud Turtle). MARLBORO CO.: Bennettsville, AOR on Lightwood Road. 18 April 2004. CR 2809. R. J. Brooks.

Pseudemys concinna (River Cooter). CLARENDON CO.: Woods Bay State Natural Area, 4 km W Olanta (33.947617° N, 79.978314° W). CUSC 2603. M. Nordgren. DARLINGTON CO.: Pee Dee Research and Education Center, 7 km N Florence. 30 March 2000. CR 2712. FLORENCE CO.: Florence. CR 2711. New county record.

Sternotherus odoratus (Eastern Musk Turtle). WILLIAMSBURG CO.: Wee Tee State Forest, NW end of Wee Tee Lake, 12.5 km E St. Stephen. 29 March 2008. CUSC 2599.

Terrapene carolina carolina (Eastern Box Turtle). MARLBORO CO.: DOR on County Road 312 4 km NE junction with US Highway 1. CR 2775.

Trachemys scripta scripta (Yellow-bellied Slider). MARLBORO CO.: Bennettsville DOR on County Road 47 at Wallace Lake. 23 July 2004. CR 2819. R. J. Brooks, J. E. Krebs, and J. D. Camper. WILLIAMSBURG CO.:CR 2808. 33.685921°N, 79.853636° W. C. W. Morris.

Squamata – Lizards

Anolis carolinensis (Green Anole). FLORENCE CO.: Lynches River County Park, 11 km S Florence. 16 October 2008. CUSC 2612. LANCASTER CO.: Forty-Acre Rock Heritage Preserve, 21 km ESE Lancaster. 9 November 2008. CUSC 2628. B. T. Camper and J. D. Camper.

Aspidoscelis sexlineata sexlineata (Eastern Six-lined Racerunner). CLARENDON CO.: Woods Bay State Natural Area, 4 km W Olanta. CR 2763. New county record. G. Haught. One individual collected on the south sand rim of the bay. MARLBORO CO.: 1 km E Fulton. 6 July 2000. CR 2702.

Ophisaurus ventralis (Eastern Glass Lizard). MARLBORO CO.: Blenheim (34.40793° W, 79.54321° W). CR 2817. R. J. Brooks.

Plestiodon fasciatus (Common Five-lined Skink). CLARENDON CO.: Woods Bay State Natural Area, 4 km W Olanta. 18 March 2000. CR 2719. One individual collected on the south sand rim of the bay.

Plestiodon inexpectatus (Southeastern Five-lined Skink). DILLON CO.: Little Pee Dee State Park Bay Heritage Preserve. 3 April 2004. CR 2822. Two specimens collected along the south sand rim of the bay. FLORENCE CO.: Lynches River County Park, 11 km

S Florence. 11 September 2008. CUSC 2609.

Plestiodon laticeps (Broad-headed Skink). Marlboro Co.: Bennettsville, 4554 Lightwood Road. 18 April 2004. CR 2820. R. J. Brooks.

Sceloporus undulatus (Eastern Fence Lizard). Clarendon Co.: Woods Bay State Natural Area, 4 km W Olanta. 18 March 2000. CR 2715. One individual collected on the south sand rim of the bay.

Scincella lateralis (Little Brown Skink). Lancaster Co.: Forty-Acre Rock Heritage Preserve, 21 km ESE Lancaster. 9 November 2008. CUSC 2630. B. T. Camper and J. D. Camper.

Squamata – Snakes

Agkistrodon contortrix (Copperhead). Marlboro Co.: Blenheim, DOR on Highway 38. 16 April 2004. CR 2803. R. J. Brooks. Williamsburg Co.: 33.547349°N, 79.760276°W. 28 May 2004. CR 2826. C. W. Morris.

Agkistrodon piscivorus piscivorus (Eastern Cottonmouth). Marlboro Co.: Blenheim (34.38842° N, 79.64011° W). 13 August 2004. CR 2815. R. J. Brooks.

Carphophis amoenus amoenus (Eastern Wormsnake). Chesterfield Co.: Sand Hills State Forest, 2.8 km W Patrick. 26 June 1997. CR 2397. Darlington Co.: Great Pee Dee River Heritage Preserve, 19.6 km NNE Florence. 25 March 2000. CR 2706. Marlboro Co.: Bennettsville. 17 April 2004. CR 2825. R. J. Brooks.

Coluber constrictor (North American Racer). Williamsburg Co.: DOR on Highway 512 9 km E of 34.78366°N, 79.76848°W. 1 July 2003. CR 2773.

Coluber flagellum flagellum (Eastern Coachwhip). Marlboro Co.: DOR on Highway 177, 4.8 km S North Carolina State Line. 6 July 2000. CR 2776.

Crotalus horridus (Timber Rattlesnake). Marion Co.:. 1 km N Britton's Neck, DOR on Highway 908. 9 October 1996. CR 2652. First voucher specimen for Marion County. Marlboro Co.: 5.7 km SSE Blenheim. 8 September 1999. CR 2708. Williamsburg Co.: DOR on Highway 521 (33.549845°N, 79.759195°W). 15 May 2004. CR 2828. C. W. Morris

Diadophis punctatus punctatus (Southern Ring-necked Snake). Darlington Co.: Pee Dee Research and Education Center, 7 km N Florence. 30 March 2000. CR 2710. Marlboro Co.:Bennettsville. 17 April 2004. CR 2824.. R. J. Brooks.

Farancia erytrogramma (Rainbow Snake). Florence Co.: Lynches River County Park, 11 km S Florence. 2 April 2008. CUSC 2606. P. Johnson. DOR on County Park Road at park entrance gate.

Nerodia erythrogaster erythrogaster (Red-bellied Watersnake). Marlboro Co.: DOR on Highway 38, 6.6 km S Bennettsville. 6 July 2000. CR 2704. Williamsburg Co.: Wee Tee State Forest, NW end of Wee Tee Lake, 12.5 km E St. Stephen. 1 April 2006. CR 2796.

Nerodia fasciata fasciata (Banded Watersnake). Darlington Co.: Pee Dee Research and Education Center, 7 km N Florence. 28 August 1998. CR 2672.

Nerodia taxispilota (Brown Watersnake). Darlington Co Pee Dee Research and Education Center, 7 km N Florence. 1 October 1999. CR 2705. Marlboro Co.: Blenheim, DOR on Highway 38. 16 April 2004. CR 2802. R. J. Brooks.

Opheodrys aestivus aestivus (Northern Rough Greensnake). Darlington Co.: Lauther's Lake, 13.3 km NE Florence. 29 March 2006. CR 2792. Williamsburg Co.: DOR on Highway 512 15 km E of 34.78366°N, 79.76848°W. 1 July 2003. CR 2771.

Pantherophis guttatus (Red Cornsnake). Marlboro Co.: Wallace, DOR on County Road 165. 18 April 2004. CR 2801. R. J. Brooks.

Pantherophis alleghaniensis (Eastern Ratsnake). Williamsburg Co.: 33.69558°N, 79.847886°W. June 2004. CR 2806. C. W. Morris.

Tantilla coronata (Southeastern Crowned Snake). Florence Co.: Lynches River County Park, 11 km S Florence. 20 April 2000. CR 2707.

Thamnophis sauritis sauritis (Common Ribbonsnake): Williamsburg Co.: Wee Tee State Forest, NW end of Wee Tee Lake, 12.5 km E St. Stephen. 1 April 2006. CR 2793.

Virginia valeriae valeriae (Eastern Smooth Earthsnake). Darlington Co.: Dargan Farm, 3.2 km N junction County Roads 173 and 35. 22 October 2001. CR 2769. D. Daniel.

Acknowledgments.—All specimens were collected under South Carolina Scientific Collecting Permits. I thank J. Stowe of SC-DNR for access to the South Carolina Heritage Preserves. I am grateful to B. Kittrell and G. Askew for allowing me to work at the Pee Dee Research and Education Center. I am indebted to several students and alumni for providing specimens including R. J. Brooks, D. Daniel, C. W. Morris, and M. Nordgren. Funding was provided by faculty development grants from Francis Marion University.

The distribution records reported here are the results of drift fence/pitfall trap sampling coupled with dip-netting, funnel trapping, and random encounters at several localities in southwestern Indiana during 2009. Several of these records fill in gaps between counties where the individual species had not previously been reported (see Minton 2001). The coordinates given for each species were recorded with a handheld Garmin® GPSMAP 76CSx. Datum for the GPS was set at NAD 83. Specimens were verified by Christopher A. Phillips at the Illinois Natural History Survey (INHS). All new county records are backed by vouchered photographs housed at INHS.

Caudata — Salamanders

Ambystoma opacum (Marbled Salamander). Greene Co.: Hillenbrand Fish and Wildlife Area, ca. 0.34 km SW of the intersection of 600N and 1500W (39.11066°N, 87.22505°W). 25 March 2009. Vanessa C. Kinney and Jennifer L. Heemeyer. INHS 2009ab. Adult specimen captured in a pitfall trap outside of an ephemeral wetland.

Ambystoma tigrinum (Eastern Tiger Salamander). Clay Co.: Approximately 9.1 km WNW of Clay City (39.290601°N, 87.218976°W). 07 April 2009. Nathan J. Engbrecht. INHS 2009ac. Single adult captured in a funnel trap in a cattle pond. This record partially fills a gap in the range of this species in SW Indiana. Greene Co.: Hillenbrand Fish and Wildlife Area, ca. 0.14 km SW of the intersection of 650N and 1500W (39.119404°N, 87.22371°W). 08 March 2009. Vanessa C. Kinney, Jennifer L. Heemeyer, and Michael J. Lannoo. INHS 2009aa. Adult specimen captured in a pitfall trap outside of a semi-permanent wetland.

Notophthalmus viridescens (Eastern Newt). Daviess Co.: Approximately 5 km W of the intersection of Hwy 231 and Hwy 558 (38.896501°N, 86.927999°W). 21 July 2009. Nathan J. Engbrecht. INHS 2009ad. Single larva captured in an artificial pond. This record partially fills a large gap in the range of this species in SW Indiana. Greene Co.: Hillenbrand Fish and Wildlife Area, ca. 0.34 km SW of the intersection of 600N and 1500W (39.11066°N, 87.22505°W). 23 September 2009. Vanessa C. Kinney. INHS 2009z. Eft stage newt captured in a pitfall trap outside of an ephemeral wetland.

Testudines – Turtles

Sternotherus odoratus (Eastern Musk Turtle). Greene Co.: Hillenbrand Fish and Wildlife Area, ca. 0.90 km SW of the intersection of 600N and 1500W (39.107704°N, 87.23046°W). 26 June 2009. Vanessa C. Kinney. INHS 2009y. Adult captured in a pitfall trap outside of an ephemeral wetland at the edge of a grassland and wooded area. The hind legs of this individual were malformed; it is not known whether this was caused by a predation attempt, injury, or developmental complications.

Terrapene carolina (Eastern Box Turtle). Greene Co.: Hillenbrand Fish and Wildlife Area, ca. 0.14 km SW from the intersection of 650N and 1500W (39.119404°N, 87.22371°W). 22 May 2009. Vanessa C. Kinney, Jennifer H. Heemeyer, and Michael J. Lannoo. INHS 2009x. Adult captured in a pitfall trap outside of a semi-permanent prairie wetland.

Squamata — Snakes

Clonophis kirtlandii (Kirtland's Snake). Greene Co.: Hillenbrand Fish and Wildlife Area, ca. 0.90 km SW of the intersection of 600N and 1500W (39.107704°N, 87.23046°W). 25 March 2009. Vanessa C. Kinney and Alex Robinson. INHS 2009v. Adult captured in a pitfall trap entering an ephemeral wetland at the edge of a grassland and wooded area. Extends the known range of this species in Indiana one county to the SW. Kirtland's Snakes are listed as an Endangered Species in Indiana.

Diadophis punctatus (Ring-necked Snake). Greene Co.: Hillenbrand Fish and Wildlife Area, ca. 0.34 km SW of the intersection of 600 N and 1500 W (39.11066°N, 87.22505°W). 06 September 2009. Vanessa C. Kinney. INHS 2009w. Adult captured in a pitfall trap outside of an ephemeral wetland. Partially fills a gap in the range of this species in SW Indiana.

Lampropeltis getula (Common Kingsnake). Greene Co.: Hillenbrand Fish and Wildlife Area, ca. 0.24 km SE of the intersection of 650 N and 1500 W (39.119194°N, 87.219734°W). 11 June 2009. Jennifer L. Heemeyer. INHS 2009s. Adult found on a footpath in a managed prairie. This record partially fills a gap in the range of this species in southern Indiana.

Storeria dekayi (Dekay's Brownsnake). Greene Co.: Hillenbrand Fish and Wildlife Area, ca. 0.90 km SW of the intersection of 600N and 1500W (39.107704°N, 87.23046°W). 08 March 2009. Vanessa C. Kinney, Jennifer L. Heemeyer, and Michael J. Lannoo. INHS 2009t. Adult captured in a pitfall trap outside of an ephemeral wetland near a prairie-forest edge.

Thamnophis sauritus (Eastern Ribbonsnake). Greene Co.: Hillenbrand Fish and Wildlife Area, ca. 0.34 km SW of the intersection of 600 N and 1500 W (39.11066°N, 87.22505°W). 26 April 2009. Vanessa C. Kinney and Zachary J. Terrell. INHS 2009u. Adult individual found moving along a drift fence surrounding an ephemeral prairie wetland. Partially fills a gap along the edge of this species range in Indiana.

e-mail: ed.corey@ncdenr.gov

The geographic distribution of reptiles in North Carolina (USA) was summarized by Palmer and Braswell (1995) and has been supplemented by Beane (1998), Beane and Palmer (2006), and Eskew et al. (2008). We here report additional new records based upon specimens and photographs verified by William M. Palmer and/or Alvin L. Braswell and housed at the North Carolina State Museum of Natural Sciences (NCSM) unless otherwise indicated. Geocoordinates are based on datum WGS 84.

Crocodilia – Crocodilians

Alligator mississipiensis (American Alligator). CUMBERLAND CO.: ca. 8.4 km SW Vander (34.9747°N, 78.8547°W). Summer 2002. North Carolina Wildlife Resources Commission. NCSM 65371. First voucher for county. Palmer and Braswell (1995) reported unvouchered observational records. DARE CO.: 8.5 km ESE East Lake (35.87333°N, 75.87842°W). 20 December 2007. C. P. White. NCSM 73838 (37 eggs and eggshells from failed nest). First voucher for county. Palmer and Braswell (1995) reported unvouchered observational records. Also represents the northernmost nesting record for the species in North Carolina (Palmer and Braswell 1995).

Testudines – Turtles

Apalone spinifera aspera (Gulf Coast Spiny Softshell). ROBESON CO.: 4.8 km ESE Barnesville, Lumber River State Park, Lumber River (34.38778°N, 79.00098°W). 14 August 2009. Brian S. Ball and Jessica Ball. NCSM photographic vouchers BSB 09-1. New county record. STANLY CO.: 8.9 km SE Norwood, Pee Dee River at Montgomery County line (35.1605555°N, 80.0602166°W). 18 July 2008. Bryn H. Tracy, Rick Smith, et al. NCSM photographic vouchers BHT 08-1. First photographic voucher for county. Palmer and Braswell (1995) reported an unvouchered observational record for the Stanly-Union County line.

Apalone spinifera spinifera (Eastern Spiny Softshell). BUNCOMBE CO.: 6.4 km NNE Leicester, Turkey Creek (35.704°N, 82.6689°W). 11 June 2007. Bryn H. Tracy et al. NCSM photographic vouchers ALB 12096. First photographic voucher for county. Palmer and Braswell (1995) reported unvouchered observational records.

Chelydra serpentina (Snapping Turtle). CHOWAN CO.: "near Rockyhock" (ca. 36.17°N, 76.70°W). 20 June 1988. David King and Eileen Kenny. NCSM 75972. A second specimen, NCSM 39946, was recorded in 1995. New county record.

Chrysemys picta picta (Eastern Painted Turtle). BLADEN CO.: 3.2 km NNW Carvers (34.4875°N, 78.4289°W). 4 July 2003. J. Chris Turner. NCSM 65111. New county record. Extends range ca. 80 km SE of nearest record in Cumberland County (Palmer and Braswell 1995). MOORE CO.: 7.1 km S Robbins (35.3713°N, 79.5944°W). 10 August 2003. James Callicutt. NCSM photographic voucher LTP 03-1. New county record. SCOTLAND CO.: 17.7 km NW Wagram, Sandhills Game Lands (34.989872°N, 79.511056°W). 3 March 2005. L. Todd Pusser. NCSM photographic voucher LTP 05-1. New county record.

Clemmys guttata (Spotted Turtle). CURRITUCK CO.: Knotts Island, Mackay Island National Wildlife Refuge (36.506°N, 75.972°W). 4 May 1987. Donald J. Schwab and Thomas Padgett. NCSM 65481. 5 June 1988. Donald J. Schwab. NCSM 65537. First vouchers for county. Palmer and Braswell (1995) reported an unvouchered observational record. EDGECOMBE CO.: 9.0 km NE Conetoe, Conetoe Creek (35.8759°N, 77.3934°W). 9 May 2007. Bryn H. Tracy et al. NCSM photographic vouchers ALB 12097. New county record.

Deirochelys reticularia reticularia (Eastern Chicken Turtle). COLUMBUS CO.: 8.0 km SSE Lake Waccamaw (town), Lake Waccamaw State Park along SE shore of Lake Waccamaw (34.25863ºN, 78.47922ºW). 15 January 2007. Zachary S. Barfield. Adult female nesting; NCSM photographic vouchers ZSB 07-1. New county record. Also represents the only record of any reptile depositing eggs during January in North Carolina (Palmer and Braswell 1995).

Glyptemys (= *Clemmys*) *muhlenbergii* (Bog Turtle). GASTON CO.: 1.6 km N.NE Dallas (35.3298°N, 81.1743°W). 1 August 1994. Ann B. Somers et al. NCSM 39367. Additional vouchers NCSM 64942 and 65630, were also collected within this county. First specimen vouchers for county. Herman et al. (1992) and Palmer and Braswell (1995) reported photographic records. MCDOWELL CO.: 7.6 km SW Dysartsville (35.5477°N, 81.9226°W). 23 June 2008. Gabrielle J. Graeter, Lori A. Williams, Dottie Brown, and Ida Evretjarn. NCSM 75964. First specimen voucher for county. Herman et al. (1993) and Palmer and Braswell (1995) reported photographic records. YANCEY CO.: 5.6 km ENE Celo (35.879°N, 82.146°W). 31 July 1993. Dylan and Kevin Ellis. NCSM 37460 (egg deposited by female found 31 July 1993 and released 10 August 1993). 4.5 km SE Celo (35.82°N, 82.17°W). 22 August 2001. Dennis W. Herman et al. NCSM 62165 (eggshells). First specimen vouchers for county. Herman (1986) and Palmer and Braswell (1995) reported photographic records.

Kinosternon subrubrum subrubrum (Eastern Mud Turtle). LEE CO.: 8.5 km SE Sanford (35.425°N, 79.103°W). 26–27 June 1981. Alan L. Kyles and William M. Palmer. NCSM 21616 (adult female) and 21620 (adult male). Additional vouchers (NCSM 24980 and 64795) are known from this county. New county records. MCDOWELL CO.: 7.6 km SW Dysartsville (35.5477°N, 81.9226°W). 23 June 2008. Dottie Brown, Gabrielle J. Graeter, Lori A. Williams, and Ida Evretjarn. NCSM photographic vouchers GJG 08-1. New county record.

Pseudemys concinna concinna (Eastern River Cooter). MARTIN CO.: 3.7 km S Hamilton (35.9099°N, 77.2067°W). 26 May 1994. Alvin L. Braswell et al. NCSM 36272. New county record. Two additional vouchers (NCSM 64032, 65152) are reported from this county.

Sternotherus odoratus (Eastern Musk Turtle). Warren Co.: 10.9 km NNE Macon, along Lake Gaston (36.53378°N, 78.05519°W). 15 August 2008. Jamie M. Smith. NCSM 74547 (six embryos, two unhatched eggs, and eggshell fragments from communal nest). New county record.

Terrapene carolina carolina (Eastern Box Turtle). CASWELL CO.: 5.8 km S.SW Milesville (36.2564°N, 79.4277°W). 28 April 1979. Fred Scott. NCSM 20017. New county record.

Squamata – Lizards

Anolis carolinensis (Green Anole). MARTIN CO.: 3.1 km W.NW Williamston (35.85969°N, 77.09282°W). 17 October 2003. J. Edward Corey III. NCSM 65308. New county record. An additional voucher NCSM 66632 was collected in this county. WARREN CO.: 10.9 km NNE Macon, along Lake Gaston (36.53378°N, 78.05519°W). 28 September 2008. Macy Cox. NCSM photographic voucher JMS 08-1. New county record.

Anolis (=*Norops*) *sagrei* (Brown Anole). NEW HANOVER CO.: 1.8 km NNE Wrightsville Beach (34.21862ºN, 77.78902ºW). 13 October 2008. Andrew R. Wood. NCSM 74677. New county record and first record for North Carolina. Additional specimens have been observed at this locality and at a nearby locality, 2.3 km NW of Wrightsville Beach (34.22570ºN, 77.81074ºW) (A. R. Wood and David Smith, pers. comm.), suggesting a breeding population of this invasive species.

Aspidoscelis sexlineata sexlineata (=*Cnemidophorus sexlineatus sexlineatus*) (Six-lined Racerunner). MADISON CO.: 4.3 km NW Walnut (35.8801°N, 82.7706°W). 13 September 2003. Stephen Rice. NCSM 70720. New county record. Extends range ca. 52 km WNW of nearest record in Buncombe County (Palmer and Braswell 1995).

Hemidactylus turcicus (Mediterranean Gecko). NEW HANOVER CO.: 3.1 km NNE center Wilmington (34.2614ºN, 77.9356ºW). 11 November 2003. Andrew R. Wood. NCSM 65405. New county record and first record for North Carolina. Numerous other specimens (juveniles and adults) have been observed at this locality from 2003 to 2008 (A. R. Wood and C. Keith Farmer, pers. comm.), strongly suggesting an established population.

Ophisaurus attenuatus longicaudus (Eastern Slender Glass Lizard). PENDER CO.: 7.7 km N.NE Hampstead, Holly Shelter Game Lands (34.43840ºN, 77.70270ºW). 28 September 2004. Jeffrey G. Hall. NCSM 69334. New county record.

Ophisaurus mimicus (Mimic Glass Lizard). PENDER CO.: 8.3 km N Hampstead (34.44236°N, 77.70553°W). 22 April 2004. Jerald H. Reynolds et al. NCSM 71561. New county record.

Ophisaurus ventralis (Eastern Glass Lizard). CURRITUCK CO.: Corolla (36.3828°N, 75.8345°W). 31 May 2003. Alvin L. Braswell. NCSM 64912. New county record.

Plestiodon (=*Eumeces*) *anthracinus* (Coal Skink). HAYWOOD CO.: Shining Rock (ca. 35.37°N, 82.86°W). 28 July 1962. R. Gordon. Verified by M. Elizabeth McGhee. Georgia Museum of Natural History (GMNH 2456). New county record. A second voucher, NCSM 71660, was also collected from this county.

Plestiodon (=*Eumeces*) *fasciatus* (Five-lined Skink). DARE CO.: 8.5 km SSE East Lake (35.8369°N, 75.9172°W). 14 April 2006. Jeffrey C. Beane and L. Todd Pusser. NCSM 70474. New county record. HENDERSON CO.: near Flat Rock, Carl Sandburg Home National Historic Site (35.273°N, 82.443°W). 5 June 2004. R. N. Reed. NCSM 73670. New county record. MARTIN CO.: 3.1 km W.NW Williamston (35.85969°N, 77.09282°W). 23 July 2003. J. Edward Corey III. NCSM 65067. New county record.

Sceloporus undulatus hyacinthinus (Northern Fence Lizard). CASWELL CO.: 0.6 km NNW Frogsboro. 26 May 2005. Rufus W. Gaul Jr. NCSM 67642. New county record. CATAWBA CO.: 12.2 km NNW Claremont, River Bend Park along Catawba River (35.82037°N, 81.18770°W). 5 November 2008. Jeffrey C. Beane, J. Edward Corey III, et al. NCSM photographic vouchers JCB 08-2142. New county record. CLEVELAND CO.: 3.9 km SW Boiling Springs (35.2259°N, 81.6966°W). 21 October 2008. Dennis W. Herman. NCSM 74597. New county record.

Scincella lateralis (Ground Skink). ALAMANCE CO.: 2.6 km SSE center Burlington (36.0715°N, 79.4347°W). 20 April 2006. Stanley L. Alford. NCSM 70666. First voucher for county. Palmer and Braswell (1995) reported an unvouchered observational record. CASWELL CO.: 2.1 km E Frogsboro (36.3480°N, 79.1608°W). 14 April 1984. David L. Stephan and Daniel F. Lockwood. NCSM 24917. First voucher for county. Palmer and Braswell (1995) reported an unvouchered observational record. WILKES CO.: 1.4 km N Traphill (36.3775°N, 81.0258°W). 9 May 2006. Jeffrey C. Beane, Tammy B. Sawyer, and Thomas J. Thorp. NCSM 70717. New county record. Extends range ca. 21 km WSW of nearest record in Surry County (Palmer and Braswell 1995) and partially fills range hiatus shown in Conant and Collins (1998).

Squamata – Snakes

Agkistrodon contortrix (Copperhead). FORSYTH CO.: 6.0 km W Belews Creek (36.2424°N, 80.1332°W). 5 September 2007. Lance Cook. NCSM 73663. First voucher for county. Palmer and Braswell (1995) reported an unvouchered observational record. IREDELL CO.: 5.5 km SSE Turnersburg (35.8640°N, 80.7829°W). June 2006. Gene Johnson and Deb Lazenby. NCSM photographic vouchers GJ 06-1. First photographic voucher for county. Palmer and Braswell (1995) reported an unvouchered observational record.

Carphophis amoenus amoenus (Eastern Wormsnake). WARREN CO.: 10.8 km N.NE Macon, along Lake Gaston (36.532806°N, 78.056367°W). 10 January 2009. Jamie M. Smith. NCSM 75062. New county record.

Cemophora coccinea copei (Northern Scarletsnake). ALEXANDER CO.: ca. 8.0 km NE Taylorsville, Rocky Face Mountain (35.972°N, 81.109°W). 7 April 2008. Michael S. Coone and Cerce Coone. NCSM photographic vouchers MSC 08-1. New county record. ANSON CO.: 4.7 km E Lilesville (34.9656°N, 79.9373°W). 11

August 2006. Jeffrey C. Beane and L. Todd Pusser. NCSM 71484. New county record.

Crotalus horridus (Timber Rattlesnake). Gates Co.: 0.5 km N Sandycross (36.379467°N, 76.549425°W). 6 June 2009. Lacey Wilkins and J. Chris Turner. NCSM photographic vouchers JCT 09-1. New county record. Lincoln Co.: 2.9 km E Triangle (35.4784°N, 80.9643°W). 24 August 2003. D. Crow. NCSM 65177. First specimen voucher for county. Palmer and Braswell (1995) reported a photographic record and Brown (1992) reported unvouchered observational records. Martin Co.: 14.5 km SSW Jamesville (35.6977°N, 76.9762°W). 14 April 2006. J. Edward Corey III. NCSM 70464. New county record. A second specimen, NCSM 70722, from the county was also vouchered.

Farancia abacura abacura (Eastern Mudsnake). Montgomery Co.: 11.9 km SE Emery (35.1709°N, 79.6310°W). 14 July 2006. Jeffrey C. Beane. NCSM 72081. First voucher for county. Palmer and Braswell (1995) reported an unvouchered observational record.

Farancia erytrogramma erytrogramma (Rainbow Snake). Chowan Co.: 1.4 km S center Edenton, along Queen Anne Cr. (36.0561°N, 76.6059°W). 2 April 2008. Daniel Grother. NCSM photographic vouchers DG 09-7. First photographic voucher for county. Palmer and Braswell (1995) reported an unvouchered observational record.

Heterodon platirhinos (Eastern Hognose Snake). Alamance Co.: 1.0 km WSW Ossipee (36.1688°N, 79.5236°W). 28 October 2006. Julie P. Litten. NCSM photographic vouchers JPL 06-1. New county record. Wilkes Co.: 4.7 km WNW Traphill (36.3707°N, 81.0651°W). Ca. September 2003. David T. Sawyer and Tammy B. Sawyer. NCSM 65638. New county record.

Lampropeltis calligaster rhombomaculata (Mole Kingsnake). Alexander Co.: 3.2 km ENE Millersville (35.8993°N, 81.1525°W). 28 September 2004. Michael S. Coone. NCSM 71480. New county record. Caswell Co.: 5.5 km SSE Yanceyville (36.358821°N, 79.310371°W). 12 April 2007. Kendrick C. Weeks, Jeff Marcus, and Anne Brown. NCSM photographic vouchers KCW 07-1. New county record. Franklin Co.: 3.5 km N Louisburg (36.1287°N, 78.2961°W). 26 August 2007. Alvin L. Braswell. NCSM 73598. New county record. Martin Co.: 9.8 km ESE Beargrass (35.72439°N, 77.03581°W). 10 April 2009. J. Edward Corey III. NCSM 75890. First voucher for county. Palmer and Braswell (1995) reported an unvouchered observational record.

Lampropeltis getula getula (Eastern Kingsnake). Chowan Co.: 2.6 km WSW Hancock (35.0909°N, 76.6545°W). 9 June 2009. Elizabeth Hanrahan. NCSM photographic voucher EH 09-1. First photographic voucher for county. Palmer and Braswell (1995) reported an unvouchered observational record.

Lampropeltis triangulum elapsoides (Scarlet Kingsnake). Cumberland Co.: ca. 9.7 km E.NE Spring Lake, Carver's Creek State Park (35.1839°N, 78.8714°W). 22 April 2007. J. Edward Corey III, Perry Aycock, and Ross Maynard. NCSM photographic vouchers JEC 07-1. New county record.

Lampropeltis triangulum triangulum (Eastern Milksnake). Polk Co.: 5.2 km WNW Tryon (35.2229°N, 82.2923°W). 14 September 2003. Dale A. Jackan. NCSM 65223. New county record. Conant (1943) reported a specimen of *L. t. elapsoides* from Polk County near Tryon, but noted that it in some respects resembled an *L. t. elapsoides* x *temporalis* intergrade. That specimen is now apparently lost (Palmer and Braswell 1995). The specimen reported here (NCSM 65223) conforms morphologically to *L. t. triangulum*.

Nerodia erythrogaster erythrogaster (Red-bellied Watersnake). Durham Co.: Ca. 8.5 km SE Bahama, Butner Game Lands (36.1154°N, 78.8057°W). 10 June 2003. David G. Cooper. NCSM 64915. New county record. Additional vouchers (NCSM 72496, NCSM 72497) were also collected in this county. Granville Co.: Ca. 4.2 km WSW Butner, Butner Game Lands (36.117°N, 78.798°W). 10 May 2003. Joseph S. Zawadowski. NCSM 64806. New county record. Together, these records extend range ca. 31 km NW of nearest records in Wake County (Palmer and Braswell 1995).

Nerodia taxispilota (Brown Watersnake). Chowan Co.: 1.4 km S center Edenton, Queen Anne Cr. (36.0561°N, 76.6049°W). 12 April 2009. Daniel Grother. NCSM photographic voucher DG 09-1. New county record.

Pantherophis guttatus (Red Cornsnake). Washington Co.: 3.9 km SE Roper (35.8599°N, 76.5775°W). 30 April 2005. Rufus W. Gaul Jr. et al. NCSM 67725. New county record. A second voucher specimen, NCSM 68727, was also collected from the county.

Regina rigida rigida (Glossy Crayfish Snake). Pender Co.: "near Maple Hill" (ca. 34.67°N, 77.71°W). Ca. 1982. James Estes and Jutta Bray. NCSM 75969. New county record.

Regina septemvittata (Queen Snake). Rockingham Co.: 14.0 km SSW Reidsville, Haw River State Park property along Haw R. (36.25542°N, 79.75789°W). 15 November 2007. J. Edward Corey III. NCSM 73817. New county record.

Sistrurus miliarius miliarius (Carolina Pigmy Rattlesnake). Pitt Co.: 1.2 km NE Grimesland (35.5709°N, 77.1822°W). 4 August 2002. Zachary R. Orr. NCSM 65446. New county record. Extends range ca. 11 km W of nearest record in Beaufort County (Palmer and Braswell 1995, Braswell et al. 2003). Tyrrell Co.: 8.0 km E Gum Neck, Grapevine Landing (35.7179°N, 76.0615°W). 18 October 2005. Woody Webster and John Fear. NCSM 69664. New county record. Extends range ca. 25 km ENE of nearest record in Hyde County (Braswell et al. 2003).

Storeria dekayi dekayi (Northern Brownsnake). Martin Co.: 2.9 km W Williamston (35.85582°N, 77.09362°W). 13 March 2003. J. Edward Corey III. NCSM 64550. New county record.

Storeria occipitomaculata occipitomaculata (Northern Red-bellied Snake). Granville Co.: 5.3 km N.NW Stem (36.24704°N, 78.74015°W). 18 October 2006. Nathan A. Shepard. NCSM photographic voucher NAS 06-2. New county record. Person Co.: 2.8 km NE Bethel Hill (36.5229°N, 78.8959°W). 5 April 1977. A. L. Braswell, J. Brellenthin, and R. Yates. NCSM 17682. New county record.

Tantilla coronata (Southeastern Crowned Snake). MARTIN CO.: 3.1 km W.NW Williamston (35.85969°N, 77.09282°W). 7 March 2003. J. Edward Corey III. NCSM 64548. New county record. Extends range ca. 40 km NE of nearest record in Pitt County (Palmer and Braswell 1995).

Thamnophis sauritus sauritus (Common Ribbonsnake). CURRITUCK CO.: Knotts Island, Mackay Island National Wildlife Refuge (36.5059°N, 75.9717°W). 9 November 1986. Donald J. Schwab and Paul O'Neil. NCSM 65558 and 65559. New county records. Another voucher (NCSM 65555) was collected from this county. GASTON CO.: 4.0 km NNW center Gastonia, between Long Cr. and Rankin Lake (35.29498°N, 81.20568°W). 10 May 2008. Zachary S. Barfield. NCSM photographic voucher ZSB 08-1. New county record. MARTIN CO.: 14.8 km SSW Jamesville (35.69501°N, 76.97914°W). 11 March 2006. J. Edward Corey III. NCSM 70199. New county record. A second voucher, NCSM 70463, was also collected from this county.

Thamnophis sirtalis sirtalis (Eastern Gartersnake). CHOWAN CO.: 1.4 km S center Edenton, Queen Anne Park (36.0561°N, 76.6061°W). 26 April 2008. Daniel Grother. NCSM photographic vouchers DG 09-3. First photographic voucher for county. Palmer and Braswell (1995) reported an unvouchered observational record. MARTIN CO.: 3.4 km WNW Williamston (35.8580°N, 77.0935°W). 24 June 2006. J. Edward Corey III and J. Edward Corey Jr. NCSM 71077. New county record.

Virginia valeriae valeriae (Eastern Smooth Earthsnake). WARREN CO.: 10.8 km N.NE Macon, along Lake Gaston (36.532833°N, 78.054528°W). 25 July 2004. Jamie M. Smith. NCSM 65995 and 65996. New county records.

Acknowledgments.—We sincerely thank all those whose fieldwork resulted in new distributional records. William M. Palmer reviewed the manuscript.

The geographic distribution of Ohio's reptiles was summarized by Wynn and Moody (2006). They reported the most current record for each reptile species by county. Twelve species of turtles were represented by 408 county distribution records. Of those, only 37 percent represented specimens collected since 1976. Two species in particular were of interest as we prepared to conduct a statewide turtle survey. The Midland Smooth Softshell (*Apalone m. mutica*), a species of apparent limited distribution in Ohio, had only been documented in nine Ohio counties and five of those (55.5%) records were more than 50 years old. The Eastern Spiny Softshell (*Apalone s. spinifera*) had been confirmed in 55 of Ohio's 88 counties, but 71% of its Ohio distribution records were more than 30 years old.

In Ohio, the Midland Smooth Softshell has been reported from the Ohio River and several of its larger tributaries. It has been collected from the lower reaches of the Great Miami and Little Miami Rivers in southwest Ohio, and the Scioto River in south central Ohio. In eastern Ohio, it has been reported from the Muskingum River and the Tuscarawas River, a tributary of the Muskingum (Conant, 1951; Zemko, 1974; Wynn and Moody, 2006). Smooth Softshells generally require soft sand into which they burrow near the shoreline of rivers they inhabit. Unlike the Eastern Spiny Softshell (*Apalone s. spinifera*), the Midland Smooth Softshell avoids burrowing into gravelly sand and mud.

Aerial maps of Ohio were scanned for bends in rivers where sand is often deposited. Once located, the sites were visited and searched for Smooth Softshells. In shallow water, generally less than 20 cm, we sifted through the sand with our finger tips to feel for the carapace of buried turtles, found their posterior end, then pulled the turtles from the sand or we raked the shallows with potato rakes reaching into the water and pulling it toward the shore. Buried turtles are generally flipped upside down by the potato rake and make little attempt to escape for the first few seconds.

The distribution of the Midland Smooth Softshell in the Great Miami River was extended upstream by approximately 29 river miles into Butler County, Ohio. The range extension in the Scioto

River was far more significant. While previously known only from Scioto and Pike counties in the Scioto River, we captured turtles in Ross, Pickaway, and Franklin counties and extended the range approximately 88 river miles upstream from Camp Creek Township in Pike County, the locality that represented the record from farthest upstream until 2008.

Seven other species were collected during the survey, four of which are represented by new county records reviewed below. One of those, *Graptemys ouachitensis* had been documented in only three Ohio counties, all in the Scioto River, through 2006. An individual captured in the Muskingum River represents the first from that drainage system. The other six species collected include *Chelydra serpentina*, *Chrysemys picta*, *Graptemys geographica*, *Sternotherus odoratus*, *Terrapene carolina* and *Trachemys scripta*.

Voucher specimens were deposited into the Herpetology Fluid Collections (CMC) and photographs into the Herpetological Photodocumentation Collection (CMC HP) of the Cincinnati Museum Center's Frederick and Amye Geier Research and Collections Center. Tissue samples were taken from those specimens placed into the fluid collection. We report 17 new county records for turtles collected during the 2008 – 2009 survey. Identification of all specimens was verified by John W. Ferner. The datum for all GPS readings was WGS 84.

Apalone mutica mutica (Midland Smooth Softshell). USA: OHIO: Butler Co.: Fairfield Township. Great Miami River (39.34387°N, 84.59238°W). 29 May 2008. Paul J. Krusling and Jeffrey G. Davis. Cincinnati Museum Center (CMC 11163). Franklin Co.: Jackson Township. Scioto River (39.83235°N, 83.00908°W). 22 July 2008. Paul J. Krusling and Jeffrey G. Davis. Cincinnati Museum Center (CMC 11301). Pickaway Co.: Harrison Township. Scioto River (39.72147°N, 83.01099°W). 22 July 2008. Paul J. Krusling and Jeffrey G. Davis. Cincinnati Museum Center (CMC 11302). Ross Co.: Green Township. Scioto River (39.43317°N, 82.98454°W). 04 May 2008. Paul J. Krusling, William J. Letsche, and Jeffrey G. Davis. Cincinnati Museum Center (CMC 11166). Ross Co.: Scioto Township. Scioto River (39.3447°N, 82.98265°W). 02 November 2008. William J. Letsche. Cincinnati Museum Center (CMC 11346). Ross Co.: Twin Township. Paint Creek (39.31874 °N, 83.09517°W). 02 June 2009. Sarah Stevenson and Joe Letsche. Cincinnati Museum Center (CMC 11596).

Apalone spinifera spinifera (Eastern Spiny Softshell). USA: OHIO: Belmont Co.: Washington Township. Captina Creek approximately 500 m upstream from the State Route 148 bridge (39.90852°N, 81.01125°W). 13 July 2009. Jeffrey G. Davis, Greg Lipps Jr., and Ralph A. Pfingsten. Cincinnati Museum Center (CMC 11687). Columbiana Co.: Elk Run Township. Middle Fork Little Beaver Creek at Elkton (40.76117°N, 80.69533°W). 12 August 2009. Jeffrey G. Davis and Paul J. Krusling. Cincinnati Museum Center (CMC 11770). Fayette Co.: Union Township. Paint Creek in Washington Courthouse (39.53964°N, 83.44557°W). 05 July 2009. Paul J. Krusling and Jeffrey G. Davis. Cincinnati Museum Center (CMC 11802). Mercer Co.: Washington Township. Wabash River at Saint Anthony Road (40.50915°N, 84.74214°W). 28 July 2009. First record from the Wabash River drainage in Ohio. Jeffrey G. Davis and Paul J. Krusling. Cincinnati Museum Center (CMC 11700). Scioto Co.: Valley Township. Scioto River upstream from the State Route 348 bridge (38.88282°N, 83.01859°W). 13 September 2008. Jeffrey G. Davis and Paul J. Krusling. Cincinnati Museum Center (CMC 11308–11310). Stark Co.: Sandy Township. Little Sandy Creek on the north side of Magnolia (40.65823°N, 81.20761°W). 12 August 2009. Jeffrey G. Davis and Paul J. Krusling. Cincinnati Museum Center (CMC 11765). Tuscarawas Co.: Oxford Township. Tuscarawas River at Newcomerstown (40.27365°N, 81.59315°W). 12 August 2008. Jeffrey G. Davis and Paul J. Krusling. Cincinnati Museum Center (CMC 11313).

Chelydra serpentina serpentina (Eastern Snapping Turtle). USA: OHIO: Shelby Co.: Washington Township. Pond near Lockington (40.21613°N, 84.25694°W). 31 May 2009. Jeffrey G. Davis and Paul J. Krusling. Cincinnati Museum Center (CMC 11610).

Graptemys geographica (Northern Map Turtle). USA: OHIO: Clermont Co.: Franklin Township. Backwater of the Ohio River at Crooked Run (38.79069°N, 84.12711°W). 27 April 2008. Jeffrey G. Davis and Paul J. Krusling. Cincinnati Museum Center Herpetological Photodocumentation Collection (CMC HP 503).

Graptemys ouachitensis ouachitensis (Ouachita Map Turtle). USA: OHIO: Muskingum Co.: Cass Township. Muskingum River (40.12972°N, 81.98303°W). 24 June 2009. Paul J. Krusling and Jeffrey G. Davis. Cincinnati Museum Center (CMC 11824). Scioto Co.: Clay Township. Scioto River (38.77517°N, 82.99201°W). 18 June 2008. Paul J. Krusling and Jeffrey G. Davis. Cincinnati Museum Center Herpetological Photodocumentation Collection (CMC HP 549–550). Paul J. Krusling and Jeffrey G. Davis.

Trachemys scripta elegans (Red-eared Slider). USA: OHIO: Montgomery Co.: Mad River Township. Collected from an abandoned gravel pit adjacent to the Mad River (39.78293°N, 84.13837°W). 10 July 2008. Jeffrey G. Davis and Paul J. Krusling. Cincinnati Museum Center (CMC 11320). Lawrence Co.: Hamilton Township. Ohio River (38.56654°N, 82.80201°W). 07 July 2008. Jeffrey G. Davis and Paul J. Krusling. Cincinnati Museum Center Herpetological Photodocumentation Collection (CMC HP 483).

Acknowledgments.—We are grateful to the Ohio Division of Wildlife for funding this survey and to John W. Ferner for reviewing the first draft of this manuscript

The diversity of amphibians, and their associated ranges of life histories, habitats and breeding modes means there is no simple set of research methods which are suitable for this group of animals. Add to this a diverse set of complex and synergistic threats to population persistence, and the difficult task of conservation and management of amphibians is daunting. Fortunately, Ken Dodd has assembled some of the world experts in methods for studying amphibians across their many habitats and life history stages into an accessible text. This book was written as a reference guide and synthesis for graduate students, researchers and conservationists, and it serves this purpose well. This text provides good general discussion of methods and techniques for studying amphibians, including morphology (chapters 2, 8), physiology, disease and feeding (chapters 5, 10, 20, 21, 27), sampling for population size and distribution (chapters 4, 9, 13–16, 18, 22), experimental venues for asking detailed research questions (chapters 6, 12), and issues regarding study design and state variable choice (chapters 1, 23–25).

The emphasis of the book is to delineate new developments in amphibian research, evaluate techniques and relate to the inference possible under each, focus attention on potential biases under each method, and highlight sampling as one part of a well thought out research program. The book is a useful supplement to existing methodological texts, while it presents new material related to advances in inference models, landscape ecology, telemetry, genetics, and disease monitoring. It provides a good introduction to amphibian research, but you will most likely also need a stack of papers particular to your organism, method, and research objectives, along with existing texts on methods in amphibian ecology (Gent and Gibson 1998; Henle and Veith 1997; Heyer et al 1994).

Several chapters should be read by anyone interested in amphibian research and conservation (chapters 2, 23–26). In particular, an emphasis on carefully defined research objectives is made early on in the text (chapter 2), which is commendable, as hard thinking before any sampling is undertaken will guide the study design, methods, and modeling which will provide the strongest inference (e.g., Platt's classic 1964 paper). Many chapters repeat this emphasis on the need for clear definition of objectives. The introduction to chapter 23,'Selection of species and sampling areas: the importance to inference,' outlines Platt's steps to strong inference. Successful research relies on the careful specification of study objectives, followed by a sampling design selected to be representative of the population of interest. The choice of how, what, and where to sample must be linked to the objectives. The strongest inference combines both experimental and observational approaches.

Each chapter provides a general discussion of the methods and techniques needed to approach a research question, and many chapters discuss how a particular approach may influence the inference from the data. The summary section of most chapters is useful, as are the literature cited sections for each chapter, as the application of each method could not be treated in sufficient detail in an introductory text. It is, however, disappointing that several chapters are not as well-referenced as they may have been, or are more regionally based and limited by the experiences of the authors. Further, a separate citation index for each chapter means that novel applications of research methods for, say, physiological measurements (chapter 20) may not be readily found by someone reading the field enclosures section (chapter 12), though research objectives under each topic might certainly be related.

Most folks won't read this text cover-cover, though by doing so, one could recognize nine major research gaps highlighted across the 27 chapters: (1) relating estimates of abundance from reproductive effort (e.g., egg mass counts or larval surveys) to population size, which are complicated by potential variation in return rates of breeding adults, (2) details of foraging in field settings, which are complicated by temporal patterns of activity and prey availability and life history stage, (3) a large gap in our understanding of movement behavior and dispersal, including variation across seasons and space, (4) terrestrial ecology, especially of wetland-breeding amphibians which are unobservable throughout much of the year, (5) integration across levels of sampling detail, including issues of scaling among estimates of detection probability, false presences, occupancy, abundance, survival rates, genetic diversity and relatedness, (6) integrating unknown features of life history and distribution to guide management of amphibian populations, (7) habitat preference and use, especially across temporal and spatial scales, (8) community ecology, species richness, diversity, and interactions, and (9) integrating physiology, movement behavior, terrestrial ecology, and habitat preference to understand population dynamics and distribution.

Part 1 discusses the challenges in studying amphibians, and the importance of setting clear and focused research objectives. Chapter 2: "setting objectives in field studies" should be required

reading for all amphibian ecologists. The first sentence of the chapter summarizes an important point which is repeated in several other chapters in the text: poor planning leads to wasted resources and cannot effectively further conservation and management of amphibian species and their habitats. Defining research objectives is essential to scientific progress and the success of a research program. The authors point out that combining experimental and observation evidence are the best way to truly understand a system, which focuses research on the *causes* of an observed phenomenon. Hard thinking during the design phase of a study should narrow the types of experiments and observations that should be most important to the accumulation of knowledge (see also chapter 23). The chapter sets the proper tone for the remainder of the book, where the specific research methods are detailed.

Part 2 includes chapters on larval morphology, sampling, design and use of aquatic mesocosms, water quality and dietary assessment. The larval stage is often the target of amphibian research, for two reasons—one more practical and one more appropriate ('logistic' vs. 'strategic' considerations). Larvae are often more easily sampled and represent a critical life history stage, though important caveats include the assumption that there is a relationship between the larval and adult population sizes, and that the factors affecting larval populations are independent of the adult population. Chapter 4 provides an overview of techniques for sampling this life stage. The authors do an excellent job of detailing nine different approaches to larval sampling, and provide a 'considerations' subsection for each technique – discussing under what circumstances each technique is most useful (though perhaps this section could have benefitted from more citations of exemplary studies). Chapter 5 provides excellent detail for sampling and analysis of larval diets, including both manipulative experiments and observational studies. The literature cited section of this chapter will be especially useful.

Chapter 6 details the use and application of aquatic mesocosms using cattle tanks, plastic wading pools, and field enclosures/cages in situ. The authors provide a convincing argument for the use of mesocosms in developing strong inference as one component of a scientific course of study, in which observations lead to the development of expectations (via models), which are then tested using experiments. Notable is the absence of a discussion of artificial stream experimental systems ('flumes'), though these setups require an external source of water to maintain flow and therefore do not strictly fit the 'self-sustaining' definition provided by the authors. Many amphibians are reliant on wetland or stream habitats for at least a portion of their life cycle; chapter 7 introduces important water quality parameters and methods for obtaining appropriate values for a suite of water quality variables.

Part 3 includes chapters on marking, egg mass and nest counts, dietary assessment, tracking movements and terrestrial experimental venues. Chapter 8 gives an overview of techniques useful for marking adult animals, with a good discussion of ethical issues in the choice and application of marking technique. In particular, emphasis should be made on evaluating the potential for violation of the criteria for marking, and one may consult the mark-recapture literature for discussion of the impacts of violating one or more of the assumptions provided in the introduction to the chapter (e.g., Amstrup et al. 2005; Williams et al. 2002). A common technique for monitoring amphibian populations is the counting of egg masses or nests (chapter 9), and such counts are typically used as indices of population size. This chapter describes characteristics of a species which make egg mass/nest counts potentially useful, and discusses factors in designing a study which relies on these counts to make inference to a population status. This technique may not be suitable for many species (see table in Appendix 9.1). The use of egg mass counts as an index of population size is confounded with breeding effort, such that counts may more reasonably index the conditional probability of breeding effort, given population size. Alternatively, the presence or absence of a breeding population may be of primary interest, in which a large number of sites over a broad area are surveyed for the presence of eggs/nests. In both the abundance and site-occupancy cases, the estimation of the probability of detecting an egg mass (or nest) is critical (chapter 24, 25). In both cases, the state variable describes the annual reproductive effort, which is a function of the number of populations, population sizes, and factors influencing breeding probability.

Dietary assessments of adult and juvenile animals are an important component of management and conservation strategies for amphibians, and chapter 10 provides excellent detail on techniques for obtaining these data, as well as important considerations for study design and interpretation of data. While foraging opportunities and prey availability may be critical for population growth or persistence, these data are unknown for most species, and complexities in ontogeny, seasonal variability, and interactions with community structure, prey availability and diet make dietary assessment a large gap in our understanding of what may limit amphibian populations.

Movement within and between habitats is an important component of population ecology, though reliable and accurate estimates of movement and dispersal are difficult to obtain. Direct observation of animals is important for understanding patterns of habitat use and identification of dispersal rates, timing, and pathways. Chapter 11 provides good description of methods useful for direct observation of movement, as well as an introduction to analysis of movement data (although interested readers should see Turchin [1998] for a more detailed discussion). A major research gap involves movement behavior across seasons and under varying habitat conditions. As dispersal is a key component of population models, a focus on movement behavior is important in conservation and management decisions for amphibians.

The importance of the terrestrial life stage in amphibian population dynamics is woefully understudied, and factors underlying population change may affect terrestrial and aquatic stages differentially. There exists a critical need to better characterize terrestrial ecology (outside of factors relating to emigration/immigration at breeding sites) for amphibian management and conservation. Chapter 12 details the use of these research tools for a suite of questions in amphibian ecology and conservation, including (1) creating a venue for application or evaluation of experimental treatments, (2) capturing individuals in the course of moving among habitat patches, and (3) estimating terrestrial densities of amphibians. Table 12.1 is useful (though not exhaustive), in outlining the type of questions which have

been asked using terrestrial enclosures. As in the use of aquatic mesocosms, these research tools can be most informative when paired with large-scale surveys.

Part 4: "Amphibian populations" includes chapters on sampling methods for capturing or detecting amphibians, including trapping and area-based survey methods, 'rapid assessment' methods, auditory detections, and measuring habitat covariates. Drift fences and pitfall traps are the 'bread-and-butter' of amphibian ecologists studying wetland breeding habitats. These research tools, along with coverboards and other means of trapping free-ranging animals, are discussed in chapter 13. The chapter has a few illustrations of examples of traps and trap arrays, and discusses the application and appropriateness of passive vs. active trapping methods. For details on construction and design of trapping methods, one would be better served to consult (Heyer et al. 1994). Another old-standby method includes area-based surveys, which incorporate replicated and standardized areas of habitat surveyed and are a vast improvement over 'haphazard' surveys, from which little population-level inference may be drawn. The authors of chapter 14 outline examples of this method, and provide a useful section on design issues in applying this method (which are of course directly related to the study objectives). One omission in section 14.5.1 is that of the program GENPRES (Bailey et al. 2007), which can be useful for study design.

Rapid assessments of biodiversity are seen as useful for establishing 'baseline' information about an understudied region, though the authors of chapter 15 point out that there is a tradeoff in a large area sampled with robust inference. Incorporation of fundamentals of sampling (independence, randomization, and replication of sampling sites) could certainly improve the value of these programs. Though the authors insist that a rapid assessment has different objectives than other biodiversity inventories, I am not convinced that the reasons given are sufficient to support a biased inventory, especially when conservation and resource allocation decisions are made based on the inventory results. Chapter 18 describes approaches useful for estimating the number of species present in a study region, including both occupancy and abundance-based estimators (though estimators based on presence-only data, such as the Maxent model of Phillips and Dudik [2008], are not discussed). Though the author discusses the difference between a count (which is some fraction of the total population detected during a given survey) and abundance (which is a count of individuals adjusted for the probability of detecting an individual, given it is present and available to be counted), many traditional biodiversity estimators do not incorporate this detection bias (similarly for presence/absence data; see Chapters 23–25). With a modicum of extra effort and probabilistic site selection, these inventories can use newly developed multi-species models to improve inference (e.g., Kery and Royle [2008]; Royle and Dorazio [2008]; Zipkin et al. [2010]).

The authors of chapter 17 point out that the variability in habitat use (and condition) may be more important to the ecology of a species than single or season-specific observations. Section 17.4: "approaches for examining habitat selection" is a useful outline, though emphasis should be placed on (1) the differences among selection, preference, and use, and (2) the relationship between the probability of detecting a species at a location and the habitat characteristics, which might mask important relationships (MacKenzie 2006). Table 17.1 could be much improved with citations.

Part 5: "Amphibian communities" includes chapters on estimating diversity from field data, and applying concepts from landscape ecology to the conservation and management of amphibian populations. The information in Chapter 19 on landscape ecology and GIS methods were not included in earlier texts on methods in amphibian research. The challenge remains in describing a landscape, *as seen from the perspective of an individual amphibian*. Integrating physiology (chapters 20 and 21), habitat use and selection (chapter 17), and movement (chapter 11) is important in determining how the composition and configuration of the landscape may influence a population. The use of genetics (chapter 22) is one additional tool for describing how a landscape may influence patterns of relatedness, genetic diversity, and the definition of a population.

Part 7: Monitoring, status, and trends may be of the most interest to many. Many times, interest lies either in the abundance or the distribution of a population. Chapters 24 and 25 should therefore be read whenever either of these variables is included in the research objectives. Chapter 24 discusses two important sources of variation: (1) spatial variation in animal distribution, and (2) the probability of detecting an individual (given it is present at a site during a survey; detection probability). The underlying issue is that the detection of an individual of a species is a combination of presence and the probability the individual is observed. Both may be affected by a suite of variables, and can be related to each component (presence and detection) differently. The authors go on to provide details on how estimation methods for abundance and occupancy (and the associated rates of change in each variable) may be incorporated into studies of amphibian populations, while Chapter 25 demonstrates the bias and potential for incorrect inference when one ignores detection probability. In section 25.4, the authors discuss ways to deal with imperfect detection, which may be either at the study design stage, or after data have been collected (i.e., with models).

In the last chapter, Ken Dodd outlines important considerations for management of amphibian populations. He provides "five cardinal rules [for] developing management programs for amphibians," and provides a table (27.1) of conceptual ideas important for amphibian population management. The chapter could use better description of existing management programs and more citations, and could discuss in more depth issues with choosing among management objectives. Both wetland and terrestrial habitat management are discussed, though the discussion of headwater stream management is overlooked. Embedding management decisions in a formal process can help sort out the available management actions, and an associated monitoring program can help inform decision making by providing information as to whether the system is responding as expected (Lyons et al. 2008; Williams et al. 2002).

At US $120 (hardcover) or $60 (paper) the book is an investment, but should be a valuable addition to a herpetologist's or conservation biologist's shelf. The challenge of amphibian conservation and management will require carefully focused research questions, carefully designed surveys for distribution and associated changes, integration of genetics, abundance and distribution, and landscape ecology, and the incorporation of

these data into management decisions. This text furthers that goal, and sets a good foundation for researchers and practitioners in support of amphibian conservation and management.

Biology of the Reptilia, Volume 22. Comprehensive Literature of the Reptilia, compiled by Ernest A. Liner, Edited by Carl Gans and Kraig Adler. Society for the Study of Amphibians and Reptiles (www.ssarbooks.com). Hardcover. xx + 1366 pp. US $130.00. ISBN 978-0-916984-80-9.

ANTHONY P. RUSSELL
Department of Biological Sciences, University of Calgary
2500 University Drive NW, Calgary, Alberta T2N 1N4, Canada
e-mail: arussell@ucalgary.ca

In 1969, as a final year undergraduate student, I was excited to see (and buy) the first volume in a new series, the *Biology of the Reptilia*. This series was to be devoted to chapters written by experts in their fields on all aspects of reptilian biology. Little did I (or, I suspect, the editors) realize at the time the magnitude of the enterprise that was being entered into, and that it would be 39 years before the final chapter-based volume (Volume 21) appeared. Two years later we have the final volume in the series, a contribution that pulls together the literature resources and subject heading areas that underpin the entire synthetic overview of animals commonly known as reptiles. Over the 41 years of publication, 19 editors and compilers have overseen the efforts of 169 authors from 21 countries who have collectively contributed to 142 chapters.

Volume 22 is by far the most physically imposing of the series and comprises complete bibliographic citations for 22,652 references (as claimed on the dust jacket—I did not attempt to verify this count!!). This list occupies 990 pages, and a further 361 pages are devoted to an integrated subject index for all of the chapters. The remainder of the volume is taken up by a Preface (three pages); a Foreword (three pages) that provides a brief summary of the life and work of Carl Gans (interested readers may like to follow this up with the more detailed accounts provided by Dudley et al. 2006; Adler 2010; Bauer 2010; Bell 2010; Northcutt 2010; Rosenberg 2010); a set of photographs of all of the editors and compilers (three pages); an Introduction (four pages); a Table of Contents of the entire series (eight pages); a List of Contributors to the entire series (two pages); and a list of published volumes of the *Biology of the Reptilia* (two pages).

The series was the brainchild of Carl Gans, and his energy and drive maintained the momentum and cajoling needed to complete this daunting undertaking. Sadly Carl passed away in late 2009, shortly before the release of this final volume,

although he had seen it in proof form. The series stands as an impressive memorial to Carl's many accomplishments, and the herpetological community will be continually grateful for his insightfulness and sense of purpose in marshalling the production of this invaluable resource. Through the duration of the project the Reptilia went from being recognized as a distinct Class of vertebrates to a cluster of clades in the sauropsid lineage. This systematic transformation probably served to intensify research on this cluster of organisms, and the chapters in the *Biology of the Reptilia* have likely been contributory to this, serving to catalyze many new lines of inquiry. If this is so, then the series has fulfilled Carl's goal of facilitating new work rather than simply summarizing what was known up to a particular point in time.

Volume 22 provides us with the opportunity to reflect upon what a monumental contribution the *Biology of the Reptilia* represents. The 13,385 pages (11,997 pages for the chapter-based volumes 1–21) have involved literally hundreds of people over a time span of more than four decades. In this regard it bears comparison to other major synthetic undertakings. One that comes to mind is the assembly of the *Oxford English Dictionary*. From May 12, 1860 (the date of its formal inception), through January 1884 (when the first fascicle was published), to April 19, 1928 (when the final fascicle was published), the time elapsed was almost 68 years, resulting in 15,490 pages that traced the meanings and etymology of every word known in the English language to that time (Winchester 2003). Like the *OED*, the *Biology of the Reptilia* did not appear in parts that followed a structurally sequential pathway, but once the entire enterprise was revealed in its fully-assembled form its potential utility became greatly enhanced. This current volume provides the integrative guide to the series and will serve as a key to many future forays into the literature by reptile biologists seeking new insights and directions. It is unlikely that another exercise of this magnitude will ever be undertaken for these animals.

The sheer magnitude of the task of compiling Volume 22 is brought home in Liner's Introduction. What he expected to take him a year ended up taking 17. Liner provides information on how the compilation was accomplished, and explains how to use the bibliography. The resulting list is more than simply a merging of the reference lists for all chapters, and extensive efforts have been made to correct errors and inconsistencies. Some of these arose as a result of different authors citing the same reference in different ways, and some resulted from the differences in style practiced by the five publishers involved in the series as a whole (Academic Press, Volumes 1–13; John Wiley and Sons, Volumes 14–15; Alan R. Liss Inc., Volume 16; University of Chicago Press, Volumes 17–18; Society for the Study of Amphibians and Reptiles, Volumes 19–22).

The development of consistency is a major accomplishment, although it has, in itself, resulted in certain new errors of which the user will have to be carefully aware (see below). Because these are likely to have been introduced in a rather idiosyncratic manner, each user will likely discover them in relation to the literature that they are most familiar with but will likely not notice them in citations to literature less central to their own research interests.

Doubtless the alphabetical listing of the references will be of major service to those interested in the biology of reptiles in all its guises, but this mode of compilation also limits its searchability. What will probably turn out to be the most helpful and useful component of the volume is the integrated subject index. This serves as a guide to the entire series and allows treatments of topics and taxa to be located directly to page in all pertinent volumes.

Overall, the literature compilation appears to be accurate. I investigated this for my own chapter (Russell and Bauer 2008) and for the first chapter in the first volume (Carroll 1969). I cross-checked for all references listed under the letters "A" and "G" in both of these with the master list in Volume 22—they were all there. As mentioned above, however, the literature list is not without transcriptional errors. For example, the citation for Broili (1905) is correctly formulated in Carroll's (1969) chapter whereas Volume 22 refers to "*hohemicus*" rather than "*bohemicus*" in the title. I am sure that in most cases "corrections" that have been made to citations are effective, but I noted, by cross-checking with my own chapter (Russell and Bauer 2008) and with the original literature, that some have resulted in bibliographic miscitations. For example, the entries for George (1948, 1956) both include "*Uromastyx*" in the title. Although this is the correct spelling for the genus, it is not the form that occurs in the actual titles of these two papers (where "*Uromastix*" is employed). Similarly, all of the publications first authored by Sabine Renous are listed collectively under the name "Renous-Lécuru." This is potentially misleading because publications by this author appear under the names "Lécuru," Renous-Lécuru," and "Renous." The chosen method of compilation will likely lead to a proliferation of errors as a result of the unfortunate practice of secondary citation. Because this volume will be taken to be authoritative it is more likely to engender such introduced errors. Although I recognize that such moves were made so that all publications by a single author could be brought together, this requires prior knowledge of the association of particular names with the same individual. Inconsistency, therefore, creeps in – I note that "Halstead, L.B." and "Tarlo, L.B.H." are listed separately, even though they refer to the same individual. Overall, I feel that it would have been preferable to cite authors and titles exactly as they appear in the original publications as this allows bibliographic searching to be as exact as possible.

These relatively minor concerns aside, however, this volume constitutes an amazingly important resource that deserves a place in the library of every student of reptile biology. An inbuilt shortcoming results, of course, from the time elapsed between the publication of the first (1969) and last (2008) chapter-based volumes, meaning that literature coverage is not equally complete (as of 2010) for all subject areas covered by the series. It is also evident that the hugely valuable compiled literature list could be so much more effective if it was available in electronic, searchable format. One hopes that it will eventually be made available in that way, but until then the impressively large paper version will have to serve as the literary workhorse of herpetologists.

PUBLICATIONS RECEIVED

Mysteries of the Komodo Dragon, the Biggest, Deadliest Lizard Gives Up its Secrets, by Marty Crump. 2010. Boyds Mill Press (www.boydesmillspress.com). Hardcover. 40 pp. US $18.95. ISBN 978-1-59078-757-1.

This book by well-known herpetologist and children's author Marty Crump provides a wealth of information about *Varanus komodoensis* for younger readers. Drawing heavily on the work of Walter Auffenburg and other researchers, she provides a concise and accessible, but not watered-down, overview of the discovery, natural history, reproductive biology, and conservation status of Komodo Dragons. In addition to explaining the science, the book explains how science is done and is enlivened by photos and anecdotes of varanid researchers from Auffenburg to current students. This is not your grandfather's kid's book. In addition to conveying real information in the text, the book is provided with a bibliography of 21 "adult" references, an index, and information about the Komodo Survival Program. The "mysteries" covered include toxic saliva and parthenogenesis, but the most recent revelations regarding varanid venoms are not discussed.

Recognition and Alleviation of Pain in Laboratory Animals, by Committee on Recognition and Alleviation of Pain in Laboratory Animals (National Research Council of the National Academies). 2009. The National Academies Press (www.nap.edu). Softcover. xv + 170 pp. US $37.95. ISBN 978-0-309-12834-6.

This volume, which updates a 1992 report of the same name, defines pain, considers how animals feel pain, and how pain can be recognized and reduced in vertebrates under experimental conditions. Although the majority of the text is focused on the most commonly used laboratory mammals, the authors have made an effort to provide practical information on birds, reptiles, amphibians, and fish to help foster better care of these animals in the laboratory. It examines the relationship between pain, anxiety, fear, and stress and considers the conditions under which pain is justifiable. The bulk of the book addresses the clinical recognition of pain, pharmacologic and non-pharmacologic approaches to pain management, and humane endpoints for animals in pain, including euthanasia. The report makes discrete recommendations on alleviating pain, but recognizes that information for making such decisions is incomplete, especially for non-mammalian lab animals. An appendix overviews U.S. regulations and guidelines relating to pain recognition and alleviation. The book is extensively referenced and there is a short glossary of about 20 terms and an index. It is aimed at laboratory researchers, institutional veterinarians, animal care and use committee members, and anyone interested in the current state of both scientific and ethical issues related to animal pain.

Sexy Orchids Make Lousy Lovers & Other Unusual Natural Histories, by Marty Crump. 2009. The University of Chicago Press (www.press.uchicago.edu). x + [1] + 214 pp. Hardcover. US $25.00. ISBN 978-1-226-122185-7.

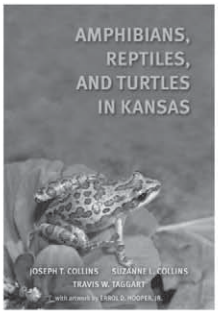
This readable volume presents a series of short vignettes illustrating the natural history of living things, with an emphasis on the interrelationships between animals of the same species, animals of different species, and animals and plants, fungi, and bacteria. The examples selected serve to highlight the diversity of such biotic interactions and focus on some of the more interesting or unfamiliar of these. Although drawn from all sorts of organisms, many examples feature amphibians or reptiles and many are derived from the author's own field experiences. Although accessible to a broad general audience, herpetologists and other field biologists will certainly enjoy the book — even if many examples are familiar to professional biologists, others may not be, and reading about so many interesting types of interactions back-to-back engenders a new appreciation for the sheer diversity and interconnectivity of life. Among the herpetological stories are those dealing with Harlequin Frog amplexus, Marine Iguanas and Sally Lightfoot crabs, alligators and the animals that share their nests, poison dart frogs and the ants that contribute to their toxicity, box turtles and the seeds they help germinate, and the buccal bacteria of Komodo Dragons. Although sources are not referenced directly in the text, the book provides an extensive bibliography of primary and secondary literature relating to the topics discussed, as well as a glossary and an index.

Photoperiodism, the Biological Calendar, edited by Randy J. Nelson, David L. Denlinger, and David E. Somers. 2010. Oxford University Press (www.oup.com). xiii + 581 pp. Hardcover. US $74.00. ISBN 978-0-19-533590-3.

This edited volume clearly illustrates how pervasive photoperiodism is in the natural world. Some of the most well known examples come from plants (e.g., flowering and

dormancy)—treated in six chapters, and insects (e.g., migration, diapause)—dealt with in five chapters, but examples are also provided from fungi, mollusks, and copepods. Seven chapters treat vertebrates, and one of these, by Zachary Weil and David Crews (pp. 399–419) reviews 'Photoperiodism in Amphibians and Reptiles.' This and other chapters discuss the mechanisms by which photoperiodic signals are decoded, the molecular and physiological bases for the regulation of body functions influenced by photoperiodism, and the resultant effects on whole organism biology, for example, reproductive activities. In the case of amphibians and reptiles the interaction of photoperiodic cues with other environmental variables, such as temperature and rainfall, are particularly important. Each chapter is well referenced and illustrated by line drawings and graphs and the book as a whole has a comprehensive index. Physiologists, endocrinologists, as well as ecologists and reproductive biologists should find this a useful, if somewhat selective, overview of this field.

The Evolution of Primary Sexual Characters in Animals, edited by Janet L. Leonard and Alex Córdoba-Aguilar. 2010. Oxford University Press (www.oup.com). ix + 537 pp. Hardcover. US $79.95. ISBN 978-0-19-532555-3.



This multi-authored volume considers the evolution of genitalia and other primary sexual characters, as well as the evolution of sexes and sexual systems. After several introductory chapters, including one by Michael Ghiselin on 'The Distinction between Primary and Secondary Sexual Characters,' the bulk of the book is devoted to examining the sexual characters of selected taxa of animals, chiefly mollusks, arthropods, and vertebrates. One chapter each is devoted to amphibians and reptiles. Lynne Houck and Paul Verrell discuss the amphibian reproductive system, sperm, sperm storage, and sperm transfer, and oviposition in caecilians, frogs, and salamanders. Tobias Uller, Devi Stuart-Fox, and Mats Olsson consider similar topics in reptiles and also present a phylogenetic analysis of testis size and sperm production. Both chapters, like others in the book, present suggestions for future research and cite many references, thereby providing entry into the literature. This work is illustrated by numerous black-and-white illustrations and graphs and has an extensive index and will be of special interest to reproductive biologists, morphologists, and evolutionary biologists.

Errata

A geographic distribution note for *Hemidactylus mabouia* (Somma 2010. Herpetol. Rev. 41:107) had been previously published (Somma 2009. Herpetol. Rev. 40:452); thus, the newer version should be disregarded. We regret the error.

In a recent natural history note (Wojnowski 2010. Herpetol. Rev. 41:216–217), the identity of the lizard involved was erroneously reported as *Aspidoscelis sonorae*, but instead appears to represent *A. tigris*. The author also notes that he mistakenly attributed confirmation of the incorrect species identification to W. Sherbrooke. He is grateful to Sherbrooke, C. J. Cole, and B. K. Sullivan for pointing out the error.

AMPHIBIANS, REPTILES, AND TURTLES IN KANSAS

By Joseph T. Collins, Suzanne L. Collins, and Travis W. Taggart
With artwork by Errol D. Hooper, Jr.

6" × 9" • hardcover with dust jacket • *xvi* + 312 pages • 497 color images • 97 color maps
65 black & white illustrations • ISBN: 978-0-9720154-5-5

Amphibians, Reptiles, and Turtles in Kansas is a book that displays the herpetofauna of Kansas in vivid color through the lens craft of co-author Suzanne L. Collins. Innovative features include the recognition of turtles (Class Chelonia) as a distinct evolutionary lineage, the inclusion of a phylogeny for the Phylum Chordata, and the elimination of subspecies for the traditionally recognized herpetofaunal groups.

With over 1,700 entries, the bibliography in this book is the most complete ever assembled for a state field guide. The range maps are in color and dots show the specific county localities for each species. The text includes the most current data for each herpetofaunal species found in Kansas, in addition to their conservation status, where relevant. Richly-illustrated identification keys can be useful in the field, as well as in the classroom and laboratory. Information on the identification, size, distribution, natural history, and pertinent literature references are included for each of the nearly 100 species of amphibians, reptiles, and turtles found in the state.

Price: $30.00 (+ $5.00 s & h for US orders; international orders please inquire for postal rates)

Announcing...

CONSERVATION OF MESOAMERICAN AMPHIBIANS AND REPTILES

Edited by Larry David Wilson, Josiah H. Townsend, and Jerry D. Johnson

Foreword by James B. Murphy

- 8½" × 11"
- hardcover with dust jacket
- *xvii* + 812 pages
- 21 contributions by 43 authors
- 44 color photographs
- 86 figures, 148 tables, 9 appendices
- ISBN 978-09720154-4-8

Mesoamerica, often called Middle America, is one of the world's major biodiversity hotspots. The herpetofauna of this region consists of approximately 1,900 species, of which about 1,000 are endemic to specific countries.

Conservation of Mesoamerican Amphibians and Reptiles (CMAR) represents the most comprehensive compilation of conservation-related herpetological contributions ever assembled for Mesoamerica. This volume will serve as a valuable reference for most future conservation work in this region.

Nearly four years in the making, CMAR contains a complete conservation assessment of the herpetofauna of this megadiverse region, in addition to distributional analyses from the perspectives of country, physiographic region, elevation, and vegetation zone. The database and wealth of information included in this work are unprecedented in the field of conservation biology.

Chapters on herpetofaunal conservation are featured for each of the Mesoamerican countries, with Mexico divided into four regions. Other feature chapters include such topics as the Global Amphibian Assessment, recent taxonomic changes, herpetofaunal distribution patterns, and a closing chapter examining the biodiversity significance, conservation status, and the future challenges we face in attempting to save the entire Mesoamerican herpetofauna. Several ancillary chapters on a host of conservation issues also are included.

The systematics of the Mesoamerican herpetofauna is discussed and brought up to date, highlighted with extensive commentary on current taxonomic problems. An addendum provides a summary of recent taxonomic publications.

This volume contains something for nearly everyone with a serious interest in herpetology, conservation biology, zoo biology, or those involved with governmental policy structure regarding conservation and/or environmental problems. Perhaps more importantly, this book will serve as a source of inspiration for future research projects, especially for biologists and conservationists who seek to salvage as much of the spectacular diversity and endemicity of Mesoamerica as possible.

A book for every serious herpetologist, conservationist, conservation organization, and zoological institution.

Price: $135.00 (+ $5.00 s & h for US orders; international orders please inquire for postal rates)

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints and Page Proofs

Reprints of notes or articles published in ***HR*** may be ordered through EZReprints (EzReprint@odysseypress.com), an online reprint ordering system. Authors will receive email notification as the issue goes to press. Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not sent for natural history notes or geographic distribution notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes. **POSTMASTER:** Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation,* and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available for purchase from the SSAR Bookstore (http://www.ssarbooks.com/). Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 840		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 840	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com. Online orders at: http://www.ssarbooks.com/.

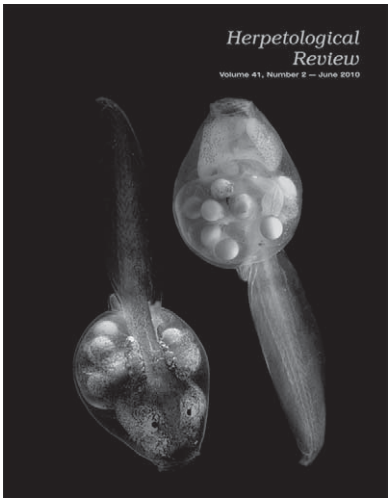
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.



To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:

http://www.ssarherps.org/pages/membership.php

Future Annual Meetings

2010 — Providence, Rhode Island, 7–12 July (with ASIH, HL)
2011 — Minneapolis, Minnesota, dates TBA (with ASIH, HL)
2012 — Vancouver, British Columbia, dates TBA (with ASIH, HL, WCH)

About Our Cover: *Anotheca spinosa*

Middle America, the waistband of the Western Hemisphere, seems to contain all of its features. Land forms, climate, soils, vegetation and fauna are more varied in Mexico and Central America than most anywhere else on earth. Owing to its contemporary mountain-building, the region boasts no fewer than four tectonic patterns that leave it rich in rugged plateaus sundered by steep escarpments and dotted with massive volcanic cones. Pristine montane rainforests at low to moderate elevations from Veracruz, Mexico, south into western Panama contain a rarely seen and engrossingly distinctive gargoyle of a frog called *Anotheca spinosa.*

It dwells in trees, usually at heights, so the monotypic *Anotheca* remains poorly known. Our knowledge of its life history derives mostly from captive observations performed 132 years after Steindachner described *Anotheca* (Jungfer 1996. Herpetologica 52:25–32; Steindachner 1864. Verh. Zool. Bot. Ges. Wien. 14:539–552). Fertilized eggs are deposited just above the water line in flooded tree holes, bamboo internodes, and other phytotelmata so the larvae must rely on the female for nutrition. She provides them with infertile eggs which often are ingested whole by the tadpoles. Depending upon need and opportunity, minute arthropods and fellow tadpoles may also be included in the diet.

William E. Duellman (pers. comm.) relates an amusing encounter between two accomplished, but feuding, herpetologists—Edward H. Taylor and Emmett Reid Dunn. Having just acquired strange anuran larvae with egg-filled body cavities, Taylor rushed back from fieldwork in Central America and made a preliminary presentation at the 1953 herpetological meetings. He believed he had stumbled upon a gravid neotenic tadpole about to lay eggs. Dunn, taking a wild guess, openly suggested that Taylor was unable to distinguish between the reproductive and digestive tracts. Turns out Dunn was correct and the larvae were subsequently found to be *Anotheca* (Taylor 1954. Univ. Kansas Sci. Bull. 36[8]:589–595). Considering how little was known about oophagous macrophage anuran larvae at the time, Taylor's error is understandable.

Likely uncommon in nature, *Anotheca* is being bred in captivity at the Atlanta Botanical Garden as part of their work with imperiled anurans from Panama. This live collection of amphibians was initially developed as a collaboration between Zoo Atlanta and the Atlanta Botanical Garden and has subsequently evolved into a resource with multiple purposes: 1) to provide an emergency genetic repository for imperiled species, 2) to provide specimens for research and education at other institutions, 3) to develop and refine captive breeding and husbandry techniques for these species, and 4) to transfer the resultant methodology to collaborators working with the same imperiled amphibian species in Panama. Success with this ambitious effort may help assure that future herpetologists might hear that rarest of nocturnal songs: the mysterious "boop-boop" of a calling *Anotheca* in the mist-shrouded treetops of Middle America.

PHOTO BY W. W. LAMAR

A female *Anotheca* kept in the Garden's "Frog Pod" was observed producing food eggs for a clutch of tadpoles from which the cover image was produced. **Danté Fenolio** used a digital Sony Alpha 100 at a shutter speed of 1/125th of a second with a 100mm macro lens set at f/25 and a Sony Macro Flash Unit to record the cover image.

Fenolio is the resident Amphibian Conservation Scientist for the Atlanta Botanical Garden's amphibian conservation program. His work with the Garden currently focuses on Darwin's Frog (*Rhinoderma*) conservation in Chile and ecological and population studies of the Georgia Blind Salamander (*Eurycea wallacei*). An avid wildlife photographer for most of his life, Fenolio is wrapping up a photographic book that focuses on wildlife that spends all or much of their lives in the dark.

SSAR BUSINESS

Thomas Beauvais Fund to Support Color Photographs in SSAR Publications

SSAR is pleased to announce the establishment of the Thomas F. Beauvais Fund to support the increased use of color in both the *Journal of Herpetology* and *Herpetological Review*. The goal of this fund is to encourage the use of high quality color images of amphibians and reptiles for both scientific and aesthetic purposes. This especially applies to new or never-before-illustrated species. Where authors have appropriate images to accompany their articles, they should contact the editor for particulars.

Thomas Beauvais is an amateur herpetologist who lives in Ann Arbor, Michigan. For several years he has been engaged in an extensive bibliographic, biogeographic, and distributional monograph on the Eastern Massasauga (*Sistrurus c. catenatus*). The accompanying photo shows Tom with an exceptionally large specimen from Indiana at the Field Museum in Chicago. Tom is a graduate of Eastern Michigan University and recently retired from a research position at NSF International, a public health and safety company in Ann Arbor. In 2001, he won a Conservation Achievement Award from the Niagara Peninsula Conservation Authority in Ontario for his cartographic and historical research on the massasauga. SSAR salutes his vision and generosity in establishing this fund, which will more fully record the natural appearance of these beautiful animals that we are privileged to study and enjoy. Those persons who wish to contribute to the Beauvais Fund may contact the SSAR Treasurer, Kirsten Nicholson (address on inside front cover).

NEWSNOTES

New Herpetology Collections Manager at LACM

The sections of Ichthyology and Herpetology at the Natural History Museum of Los Angeles County (LACM) are pleased to announce the appointment of Neftali Camacho as Collections Manager of Herpetology. Neftali has worked in Ichthyology and Herpetology for the past six years, assisting with our skeleton fungus decontamination project, curating our frozen tissue collections, and performing a variety of curatorial duties in both sections. Prior to that he was employed at the museum's Marine Biodiversity Processing Center. Neftali brings extensive natural history collections experience to his new position, as well as ex-

pertise on the herpetofauna of California. Many of you are already familiar with Neftali from specimen loan and data requests; he will continue to provide these services in Herpetology as well as overseeing the Herpetology collection and providing access and assistance to collection visitors. Neftali's appointment fills a position left vacant for the past seven years, during which time the Herpetology collection has been overseen by Ichthyology staff. Herpetology holds an estimated 178,000 catalogued specimens from around the world, with special emphasis on collections from the southwestern United States, Mexico, Central America, the Galapagos Islands, and Australia. All inquiries regarding loans, data requests, or collection visits may be directed to Neftali at 213-763-3371 or at <ncamacho@nhm.org>.

Integration of USGS Herpetology Collection Completed at UNM Museum of Southwestern Biology

The collection of amphibians and reptiles curated by the U.S. Geological Survey (USGS) Arid Lands Field Station in Albuquerque has been integrated into the University of New Mexico's Museum of Southwestern Biology (MSB). Specimen data have been merged and the combined database is now available online through several portals, including HerpNET <www.herpnet.org>.

With more than 12,300 fluid-preserved specimens and 200 skeletons, the USGS collection contains large holdings from Colorado (40%), Nevada (32%), and Nebraska, Arizona, Utah, and California (18% combined). The collection includes early (1920s-1940s) reference specimens for studies of food habits (skeletons) collected by Charles C. Sperry, as well as the Colorado State University herpetological teaching collection, with specimens collected by D. Pettus, A. W. Spencer, D. D. Post, and T. P. Maslin. A large series (3500) of reptiles collected from the Nevada Test Site in the 1960s was catalogued in 2008 and includes many Side-blotched Lizards (*Uta stansburiana*) and Western Whiptails (*Aspidoscelis tigris*), as well as other lizards and snakes. These specimens were donated by USGS scientist Phil Medica. Drs. Bruce Bury and Steve Corn of USGS have provided vital support to the collection in many ways during their studies in the western United States. Voucher specimens from surveys of national parks on the Colorado Plateau are the most recent acquisitions.

The USGS collection was relocated from Fort Collins, Colorado to Albuquerque, New Mexico when MSB collections moved to a renovated facility. Specimens previously cited in the published literature with the acronym BS/FC (Biological Surveys Collection/Fort Collins) have been assigned MSB catalog numbers and are cross-referenced with the original BS/FC catalog number. Although the specimens are property of the U.S. Department of the Interior, and primary responsibility for their care and management rests with USGS, integration of the specimens and their associated data with MSB facilitates their use by the greater scientific community.

Information and loan requests can be directed to collection managers Tom Giermakowski (MSB) at <tomas@unm.edu>; 505-277-5130, and Cindy Ramotnik (USGS) at <ramotnik@usgs.gov>; 505-277-5369.

Seeking Herpetologists with Military Experience

Joseph Mitchell and Rob Lovich are gathering information for an article on herpetologists with military experience. The article is to be published in *Natural Selections*, a newsletter produced by the U.S. Department of Defense Legacy Resource Management Program. If you have military service with your country, please consider providing information for their article. The following elements are needed:

1) A brief paragraph on your military experience—branch, where stationed, combat experience if any, other service of note, awards, rank, dates of service, and anything else you can add.

2) A copy of your CV.

3) A photograph of you holding a herp.

The authors will create a paragraph for each herpetologist and will highlight accomplishments subsequent to military service especially if in the area of management where appropriate.

Information and questions should be directed to Joseph C. Mitchell at <dr.joe.mitchell@gmail.com>.

Instituto Butantan Collection Destroyed in Fire

One of South America's largest herpetological collections, focused on snakes and numbering approximately 80,000 preserved specimens, was destroyed in a fire on 15 May 2010. The curatorial offices were not affected. Founded in 1901 by the Brazilian physician Vital Brazil as the Instituto Serumtherapico Butantan, it was renamed as Instituto Butantan in 1915. Aside from its size, the IB collection has been the focus of ongoing active research and had historical importance in that many specimens were endemic to Brazil, and represented large series, often from habitats that no longer exist. Discussions are underway regarding how the international community can come to the aid of our colleagues at Instituto Butantan.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (HerpReview@gmail.com) well in advance of the event.

7–12 July 2010—Joint Meeting of Ichthyologists and Herpetologists (ASIH / HL / SSAR), Providence, Rhode Island, USA. Information: http://www.dce.k-state.edu/conf/jointmeeting/

21–24 July 2010—33rd Annual International Herpetological Symposium, Tucson, Arizona, USA. Information: http://www.kingsnake.com/ihs/

5–8 August 2010—Southwest Partners in Amphibian and Reptile Conservation, Colorado State University, Fort Collins, Colorado, USA. Information: www.swparc.org.

10–11 August 2010—Northeast Partners in Amphibian and Reptile Conservation Annual Meeting, Acadia National Park, Maine, USA. Information: http://www.pwrc.usgs.gov/neparc/

13–15 August 2010—Midwest Partners in Amphibian and Reptile

Conservation Annual Meeting. Theme: "Blanding's Turtle Biology, Conservation, and Management." Lorado Taft Field Campus of Northern Illinois University, Oregon, Illinois, USA. Information: http://www.mwparc.org/meetings/2010/

16–19 August 2010—Turtle Survival Alliance & IUCN/SSC Tortoise and Freshwater Turtle Specialist Group Joint Symposium, Orlando, Florida, USA. Information: http://www.turtlesurvival.org/get-involved/2010-conference.

22–26 September 2010—VIII National Congress of Societas Herpetologica Italica, Abruzzo, Italy. Information: shiabruzzo2010.iscrizioni@gmail.com

12–14 November 2010—5th National Symposium on the Ecology, Status, and Conservation of the Diamondback Terrapin, at Louisiana University's Marine Consortium (LUMCON) in Chauvin, Louisiana, USA. Hosted by the Diamondback Terrapin Working Group. Information: www.dtwg.org.

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Joshua Hale or Ben Lowe; postal and e-mail addresses may be found on the inside front cover.

A listing of current contents of various herpetological journals and other publications is available online. Go to: http://www.herplit.com and click on "Current Herpetological Contents."

Partitioning of Temporal Activity in Desert Lizards

Competition between similar species coexisting in an ecological community is ameliorated if the species segregate along the lines of food, habitat, or activity time. Of these three factors, foraging ecology and habitat use have received considerable attention; however, research on temporal partitioning is much more limited. In this study, the authors investigated temporal activity in a diverse lizard assemblage in the Simpson Desert in central Australia. Three time periods were defined; sunset to sunrise (daytime), sunset to midnight (early night), and midnight to sunrise (late night), and were examined in both September and November. Ambient temperature and invertebrate prey activity were measured at these times as well. Thirteen lizard species were observed in the assemblage (*Ctenotus ariadne, Ctenotus dux, Ctenotus pantherinus, Egernia inornata, Morethia ruficauda, Menetia greyii, Ctenophorus isolepis, Ctenophorus nuchalis, Pogona vitticeps, Nephurus levis, Varanus brevicauda, V. eremius, V. gouldii*) with 77% of all captures occurring in the day. Only three species (*Ctenotus pantherinus, Egernia inornata, Nephurus levis*) were observed to demonstrate significant nocturnal activity. Abundance of invertebrates was variable, depending on time of day and month, and some lizards, in particular the skink species, had a wider degree of temperature tolerances than the agamids and varanids. The authors conclude that partitioning within the lizards in this assemblage is not evenly distributed temporally.

Impact of Low Population Densities on Fertility in Marine Turtles

Depensation, or the Allee Effect, the reduced per capita growth rate in low density populations, can have severe consequences for already dangerously small populations. Many marine turtles worldwide have suffered serious declines, primarily due to historic overexploitation. In this study, the authors conducted a meta-analysis to examine the potential for depensation on Green Turtles (*Chelonia mydas*) and Loggerhead Turtles (*Caretta caretta*). Using hatching success as an indicator of fertilization success, the authors found no evidence for depensation for either of these species in small nesting aggregations throughout the world. The authors propose a number of mechanisms which may mitigate depensation, including a polyandrous mating system, opportunistic matings between breeding aggregations, and interchange between rookeries. The authors emphasize the importance of monitoring small nesting aggregations, in part to understand the mechanisms that mitigate depensation in these species.

Senescence in Garter Snakes

Within a life-history context, evolutionary theories of senescence (aging) focus on a trade-off between investing in survival versus investing in growth and reproduction. In high mortality environments, organisms are predicted to develop rapidly and invest in high early reproduction, instead of survival and longevity. In contrast, longevity and delayed reproduction is predicted to be favored in less hazardous environments. Despite these theoretical predictions, investigating these hypotheses empirically is difficult. In this study, the authors investigated six northern Californian populations of Western Terrestrial Garter Snakes (*Thamnophis elegans*), which can be divided into high and low mortality habitats. These populations have been extensively studied and have been demonstrated to have evolved different life spans in keeping with theoretical predictions. In this study, the authors examined a number of physiological traits in neonates after stressed or control gestations to examine different responses of the two populations. Results indicated that neonates from the long-lived

populations were smaller, had more efficient DNA repair mechanisms (but also suffered higher levels of DNA damage), and had more efficient cellular antioxidant defenses and mitochondria. The authors conclude that their study highlights the interrelatedness of stress and life history evolution in reptiles.

Costs of Mate Guarding Behavior in Male Whiptail Lizards

Males of many species guard their mates following mating, which may have a number of benefits including reducing extra-pair copulations by females. Despite the potential benefits to the male in terms of fertilization success, mate guarding is also energetically costly. In this study, the authors have examined mate guarding in the Western Mexican Whiptail Lizard (*Aspidoscelis costata*), paying particular attention to the reduction in energy intake when guarding and the increase in male-male competition. The authors also tested whether males adjust their guarding behavior in relation to the perceived fecundity (as assessed by body size) of the female. Observations of a number of matings and subsequent mate guarding behaviors were made. The authors observed that males engaged in mate guarding consumed substantially smaller and less prey than non-guarding males. Further, guarding males were subject to 120% more male-male competitive behaviors than when not guarding. Finally, males were more aggressive when females were large. The authors suggest that these demonstrated costs of mate guarding, and possible survival consequences, must be less than the benefits accrued through mate guarding for this behavior to persist.

Patterns of Malagasy Chameleon Diversity Revealed

With its impressive diversity and incredibly high level of endemism, the island of Madagascar has long been an area of elevated interest for researchers studying the factors responsible for speciation and endemicity. Chameleons of the genus *Brookesia* are particularly diverse in the region (26 described species) and display a pattern of elevated microendemism, with as many as half only known from a single locality. In this paper, the authors explored three hypotheses potentially driving speciation, geographic distribution, and community assembly. First, mountains may serve as refugia during dry periods; if this is the case, endemic species would be restricted to these high-elevation regions and sister species would tend to occur on adjacent mountains. Second, watersheds may also serve as refugia during dry periods; in this scenario, watersheds with high-elevation headwaters would contain mostly wide-ranging species, endemic species would occur in headwaters with low-elevation headwaters, and sister species pairs would tend to occupy adjacent watersheds (especially low-elevation watersheds and therefore low elevation regions would exhibit greater diversity). Originally postulated by previous researchers, these first two hypotheses were suggested to be caused by Pliocene and Pleistocene climatic fluxuations. A third hypothesis, major rivers functioning as important barriers to dispersal, was also evaluated; this hypothesis predicts that the distributions of species pairs meet at major rivers and that low elevations are the most species-rich. To determine species pairs and examine the timing of speciation, using both mitochondrial and nuclear DNA data from most of the described members of the genus as well as several undescribed taxa (and including samples from multiple localities if possible), the authors simultaneously reconstructed the *Brookesia* phylogeny and inferred the divergence dates within the group. Second, distributional information was accumulated for all taxa (for the nine species known from seven or more localities, correlative niche modeling methods were employed to construct predicted distributions; otherwise point localities were used). These distributional data were used to infer regional species richness and endemism values across the island. The phylogenetic analyses revealed most of the species level diversification far predates the Pliocene. Furthermore, the patterns of species richness and sister species distribution reject rivers or watersheds as important drivers of speciation but support the mountain refugia hypothesis. This study exemplifies the importance of explicit hypothesis testing in evaluating hypotheses of evolutionary history.

Resource Use Over Different Spatial Scales in a Snake

Resource selection within a species can be broadly thought of occurring on three different spatial scales: 1) the entire geographical range of a species, 2) the home range of an individual within the landscape, and 3) specific locations within the home range. Most studies of resource selection occur on the second and third of these levels, but as resources in a landscape may be scale dependent, in order to fully understand a species habitat and resource use, wider scales must be considered. In this study, the authors have examined landscape level resource use in the Eastern Hognose Snake (*Heterodon platirhinos*), in southern New Hampshire, USA. Eight snakes were radiotracked for two years, and once landscape availability was controlled for, at the landscape level, snakes were found to choose forest-edge and old field habitats preferentially, and neglect forested habitats and

wetlands. Investigating resource allocation at the landscape level also indicated that snakes preferred low slope and sandy loam soils. These patterns were not detected when only the home range of an individual was considered. The authors therefore emphasize the importance of taking a landscape approach when investigating resource use.

Predator Avoidance Outweighs Thermal Benefits in a Gecko

Many species are faced with multiple predators, which may pose different levels of risk. According to the threat-sensitive predator avoidance hypothesis, prey should match their behavior to the level of risk posed by each predator. In this study, the authors have examined this in the nocturnal Velvet Gecko (*Oedura leseurii*), from eastern Australia, which is preyed upon by two snakes, the relatively dangerous Broad-headed Snake (*Hoplocephalus bungaroides*), which preys on geckos, and the less dangerous Small-eyed Snake (*Cryptophis nigrescens*), which preys on skinks. In the laboratory, geckos show generalized antipredator behaviors to chemical cues from both snakes, however, in nature, these behaviors may have costs, in particular thermal costs. In this study, a number of laboratory trials were used to investigate this question. In the first trial, geckos were presented with two identical shelters, one unscented and the other containing chemical cues from either the Broad-headed or Small-eyed Snake. Next, geckos were presented a cold unscented shelter and a warm shelter, again scented with either Broad-headed or Small-eyed snake chemicals. Finally, two warm shelters were presented, this time one was scented like the Broad-headed Snake, and the other like the less dangerous Small-eyed Snake. In each trial, regardless of the thermal suitability of the shelter, geckos avoided equally shelters scented with either snake, preferring to remain outside a shelter when both were scented, suggesting that Velvet Geckos treat these snakes as equally dangerous. These results were then confirmed in a natural setting, with geckos avoiding sites previously used by both snake species.

Function of Tentacles in the Aquatic Snake, *Erpeton tentaculatus*

The Tentacled Aquatic Snake (*Erpeton tentaculatus*), has a unique pair of scaled tentacles projecting from the rostral margins of the head. For over a century their function has remained a source of contention, with suggestions that they aid in camouflage, act as lures or ornaments, or aid in the detection of prey by sensing water movement. In this study, in an attempt to shed light on the function of these tentacles, the authors investigated snake behavior and tentacle morphology, induced the optic and trigeminal nerves, and mapped the resulting visual and somatosensory responses in the optic tectum and trigeminal ganglion, respectively. Dissection and microscopy failed to reveal minute sensory structures (which could bestow electromagnetic reception) associated with the tentacle scales; however tentacles were found to be heavily innervated via the trigeminal nerve (as is the pit organ of crotaline viperids). Furthermore, recordings of nervous impulses returning from the tentacles revealed that the tentacles were able to sense very minute water movements (equivalent to the force exerted by 8mg). Finally, snakes were found to strike accurately at digital fish under both normal and infrared conditions, suggesting that detection of water movement alone was sufficient to locate prey. The authors suggest that these tentacles operate alongside the visual system to aid in prey detection, especially in low-light environments.

Are Amphibians Good Indicators of Ecosystem Health?

Amphibians are often considered important indicators of ecosystem health. This is primarily because they are expected to be sensitive to a range of contaminants as they possess permeable skin, a complex terrestrial and aquatic life cycle, and a relatively simple immune system. In this study, the authors have examined the veracity of this reputation, completing a meta-analysis comparing the sensitivity to environmental challenges of amphibians relative to other taxa. Almost twenty-four thousand studies involving 1075 species and 73 chemical agents were examined. Overall, the results suggested that amphibians demonstrate only moderate responses to waterborne toxins. Amphibians are relatively insensitive to heavy metals and pesticides, but demonstrate high sensitivity to phenols, a class of toxins that has been largely overlooked in amphibian studies. The authors suggest that amphibians may not serve as very good barometers of ecosystem health and are prone to persisting in areas that have already been severely impacted. While chemical contaminants may play a role in amphibian declines, this may be indirect, reflecting the population loss or extinction of more sensitive taxa, in particular invertebrates.

Kerby, J. L., K. L. Richards-Hrdlicka, A. Storfer, and D. K. Skelly. 2010. An examination of amphibian sensitivity to environmental contaminants: are amphibians poor canaries? Ecology Letters 13:60–67.

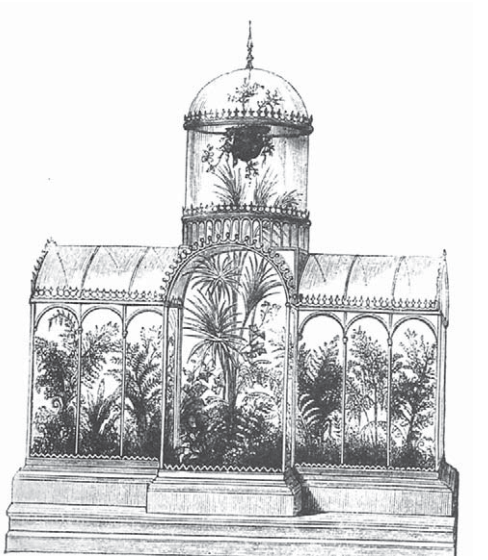
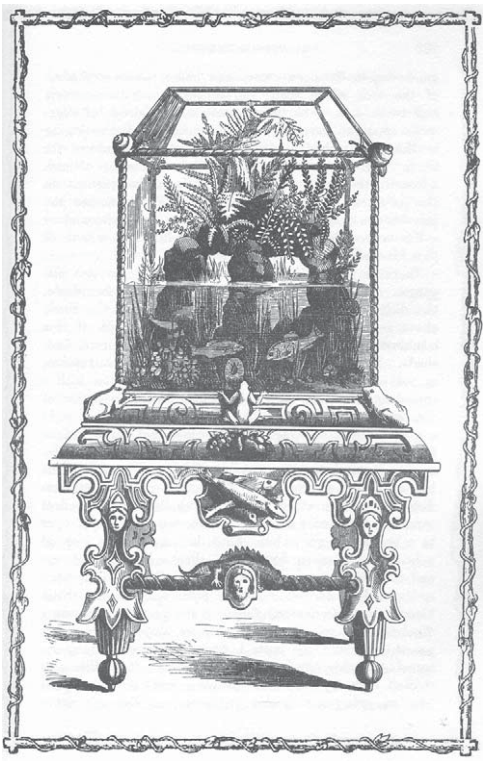
SEVERAL OF THE LADIES IN SOUTHPORT HAVE PURCHASED PETS AMONG THEM, AND IT MAY BE THAT NO SOUTHPORT LADY WILL CONSIDER HER ESTABLISHMENT PERFECT WITHOUT A BABY ALLIGATOR TO BASK ON THE HEARTH RUG, AND GO OUT ON A WALK ON THE PROMENADE WITH HER. WHEN THE PET DEFUNCTS, HE CAN BE STUFFED, GILT, AND PUT IN THE HAT FOR AN ORNAMENT, DON'T YOU KNOW?



—Frank Buckland in *Notes and Jottings from Animal Life* in 1882

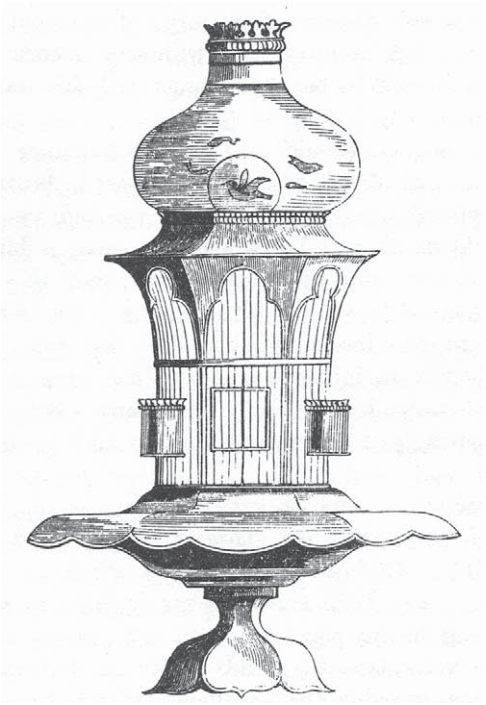
Nature Encased in Glass

In 1688, the French produced polished plate glass in large sizes by casting and hand polishing. Over 45 years later in the United Kingdom, Robert Lucas Chance introduced improved cylinder sheet glass using a German process to produce finer quality and larger panes. "A better system of making sheet glass, from blown cylinders, was introduced into England in 1832 by Chance Brothers and Bontemps. Although the new method, already established in Germany and France, required five types of skilled workers, it was cheaper, produced bigger sheets, and was free from the blemish in the centre… But after only seven years Chance Brothers devised a process by which the sheets could be ground and polished like plate glass… The manufacture of plate glass was introduced into England from Northern France in 1773…" (Derry and Williams 1961:594–595). This glass was used to create the first Crystal Palace in London in 1851. The process was used extensively until early in the 20th Century to make window glass. From this period onwards machines were developed to automate the production of window glass.



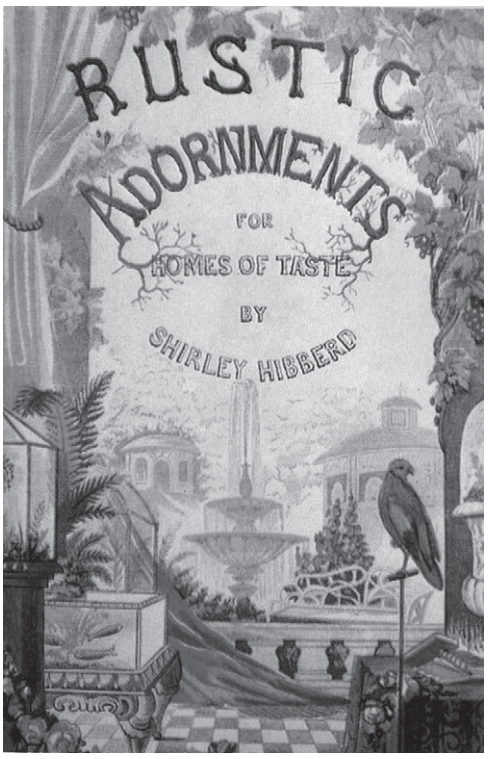
There is no question but that the availability of inexpensive window glass was one of the main factors for the rise of fern cases, aquaria, terraria, and vivaria in Europe. Fanciers interested in the behavior and biology of fishes, tadpoles, and newts were now able to look closely at them in an aquarium rather than peering into a pond or small bottle to catch a fleeting glimpse.

In 1829, Nathaniel Bagshaw Ward discovered that two seedlings, a grass and a fern, had *accidentally* sprouted in a closed glass bottle, containing a layer of damp soil he was using to pupate a sphinx moth chrysalis. He experimented with other closed glass containers and found that he could keep a number of ferns successfully. Glass was expensive as it was subject to a heavy excise tax (to pay for the Napoleonic wars) until 1845. After the tax was repealed, glass was affordable so Ward's "Closely Glazed Cases" were available widely and his invention reached its full potential. Wardian Fern Cases became the rage and virtually every wealthy Victorian lady's drawing room had fern-growing cases. Shirley Hibberd (1856) loved ferns: "Plumy emerald green pets glistening with health and beadings of warm dew." Pteridomania, the craze for ferns, was fueled by books such as *The Ferns of Great Britain* by Anne Pratt in 1855, *Hardy Ferns: How I Collected and Cultivated Them* by Nona Bellairs in 1865, and even as late as 1905 with George Schneider's work called *Choice Ferns for Amateurs: Their Culture and Management in the Open and Under Glass*. Well-dressed Victorian women often collected wild plants and animals for their enclosures, as seen in the picture "Gathering Ferns" from *London Illustrated News* in 1871. The picture is by William Kay Blacklock and is available on the web at http://goldenagepaintings.blogspot.com/2009/02/william-kay-blacklock-gathering-ferns.html. Orchids and other tropical plants were kept in fern-cases as well.



Wardian Fern Cases could be very elaborate. This terrarium was modeled after the Crystal Palace of London's Great Exhibition in 1851.

By the mid-1800s, the drawing rooms of the wealthy were often filled with a myriad of glass containers, large and small, housing plants and animals. All of these items were sometimes advertised in natural history books available during this time. One of the curious facts is that fern and aquarium crazes were almost always feminine interests during the Victorian era. "But the role of women as encouragers of natural history must not be underrated. It is unlikely that so many natural history societies, museums, zoological and botanical gardens and public aquaria would have been founded if they could not have relied on regular female support." (Barber 1980). Charles Kingsley described the Victorian lady naturalist at home in *Glaucus* in 1855: "I have seen the young London beauty, amid all the excitement and temptation of luxury and flattery, with her heart pure and her mind occupied in a boudoir full of shells and fossils, flowers and sea-weeds, and keeping herself unspotted from the world, by considering the lilies of the field, how they grow." Why were



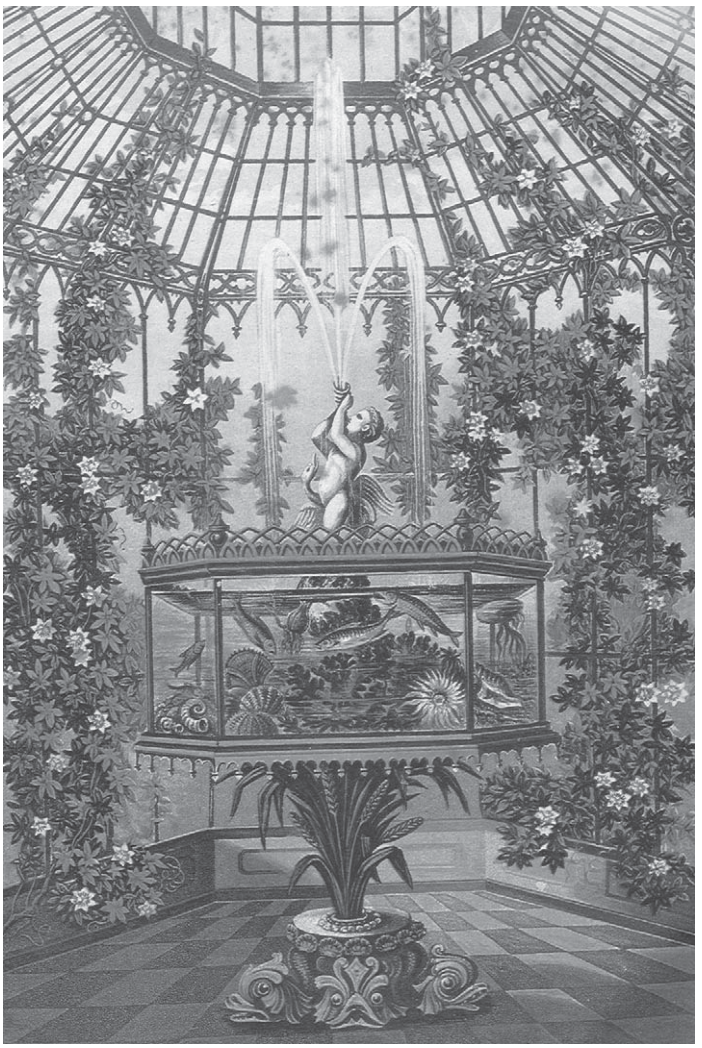
In 1856, Shirley Hibberd published *Rustic Adornments for Homes of Taste*. Pictured here is Aquarium combined with Fernery. Note frogs at base.

so many natural history books and periodicals published during this period? Victorians believed that it was slightly common to obtain animals and plants for parlors and drawing rooms simply for amusement; if flora and fauna were to be shown, there had to be an educational component attached to their passion for collecting. George Brettingham Sowerby the Second in *Popular History of the Aquarium* put it this way in 1857: "Nor is it only for amusement that such parlour oceans and lakes are prepared and stocked; they are invaluable as a means of instruction."

Combination aquarium and bird cage from *Rustic Adornments for Homes of Taste*. At top of enclosure are two bowls. Birds had access (from lower wire cage) to smaller bowl within the larger one where they were juxtaposed to fishes swimming around them. This was a popular Victorian design feature.

In 1856, the pioneer naturalist Shirley Hibberd published *Rustic Adornments for Homes of Taste and Recreations for Town Folk in the Study and Imitation of Nature* . This is the most complete book published during the Victorian era covering fern cases, marine and freshwater aquaria, aviaries, apiaries, and outdoor gardens and it is one of the most beautiful with elaborate drawings and colored floral borders on each page. Hibberd wrote in the Preface, "Whatever serves to heighten the enjoyments of home, and add fresh graces to the domestic hearth, must be worthy of encouragement and culture."

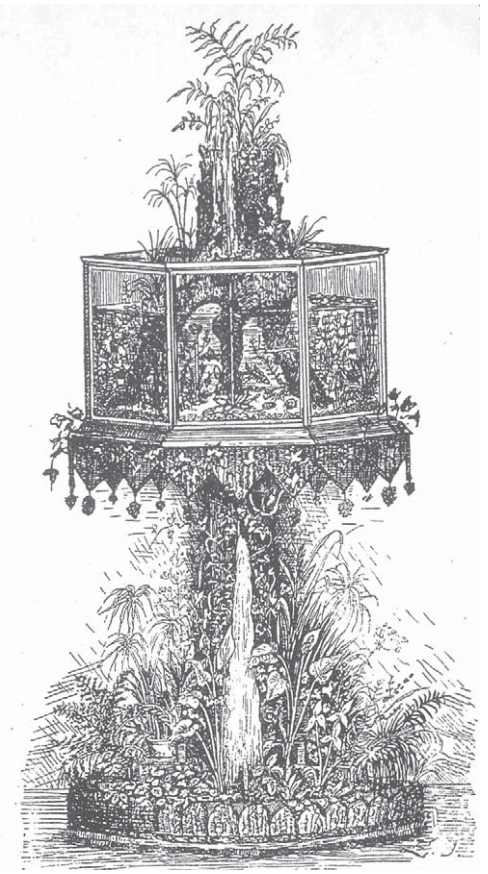
Cover from *Rustic Adornments for Homes of Taste*.



But there was a downside to the fern craze: "The poor Ferns, like the wolves in olden times, have a price set upon their heads, and they in like manner will soon disappear. We must have 'Fern laws,' and preserve them like game" (Bellairs 1865). Another problem which surfaced was that ferns quickly died in the polluted London air. As interest in ferns began to wane in England, the development of aquaria filled the void. "When every drawing-room contained a fern case, they began to seem a little dull, or even—horrid thought!—a little vulgar." (Barber 1980.).

From Land to Water

The keeping of goldfish substantially predates the aquarium craze, dating back to at least 1000 AD in China. The Chinese exported goldfish breeding to Japan and Korea around 1500 AD. Goldfish reached Europe around the beginning of the 17th Century and the US in 1876. These fishes were bred to be seen from above in shallow porcelain bowls.



In 1850, Robert Warington kept two small goldfish and a *Valisneria spiralis* plant in a twelve-gallon tank for almost a year without changing the water. He is credited with discovering the "Balanced Aquarium." During the same period, Philip Henry Gosse was independently pursuing the same experiments. Gosse published *A Naturalist's Rambles on the Devonshire Coast* which described his somewhat unsuccessful adventures at aquarium-keeping. In 1853, he said "Let the word AQUARIUM then be the one selected to indicate these interesting collections of aquatic animals and plants."

Warington and Gosse were important figures in contributing to the new aquarium craze in Victorian England. In 1856, Gosse wrote the first book on the marine aquarium entitled *A Handbook to the Marine Aquarium* . . . and it contained an advertisement by W. Alford Lloyd: For Sale—15,000

Some aquarium presentations were stunning. Illustration from *Cassell's Household Guide* in 1869?–1871?.

specimens comprising over 200 genera in 50 large glass aquaria. Other authors published books on aquarium keeping: *Ocean Gardens: The History of the Marine Aquarium, and the Best Methods Now Adopted for its Establishment and Preservation* by H. Noel Humphreys in 1857; *The Marine Aquarium: Directions for its Preparation and Management* by R. M. Stark in 1857; *Common Objects of the Sea-Shore* by Reverend John G. Wood in 1857; *The Family Aquarium; or, Aqua Vivarium ... Being a Familiar and Complete Instructor upon the Subject of the Construction, Fitting-up, Stocking, and Maintenance of the Fluvial and Marine Aquaria* by Henry D. Butler in 1858; *Cassell's Household Guide* in 1869?–1871?; *The Student's Aquarium (Marine and Fresh Water): How to Make and Manage* by S. Jacob in 1886; *The Amateur Aquarist* by Mark Samuel in 1894; and *Das süsswasser-aquarium. Geschichte, flora und fauna des süsswasser-aquariums, seine anlage und pflege* by Ernst Bade in 1898. Some of these books offered instructions for collecting animals and plants at the seashore and early pictures again show Victorian women with billowing dresses, buckets, and long-handled dip nets searching the tide-pools (see Bedell 2009).

Beautiful aquarium from *Das süsswasser-aquarium. Geschichte, flora und fauna des süsswasser-aquariums, seine anlage und pflege* by Ernst Bade in 1898.
